This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

BIBLIOTHECA · BODLEIANA ·

PRINTED BY WILLIAM CLOWES,
Duke Street, Stamford Street, Lambeth.

PREFACE TO VOLUME THE FIRST.

In the course of the regular publication of the Numbers and Parts of the Penny Cyclopædia, the purchasers of the work will have been enabled to compare its general execution with the announcements of the original Prospectus. The completion of a volume appears to call upon the Conductors for a few explanatory observations.

The plan of this work differs in a considerable degree from most other Cyclopædias. These have generally given elaborate treatises on each branch of knowledge, often referring for the explanation of each term, as it occurs in the alphabetical order, to the general treatise. The plan of the Penny Cyclopædia, as it is specially intended as a book of reference, is not to attempt to form systems of knowledge, but to give pretty fully, under each separate head, as much information as can be conveyed within reasonable limits. But whilst it endeavours to present in detail the explanation of those terms of Art and Science, the right understanding of which is independent of any system, it also attempts to give such general views of all great branches of knowledge, as may help to the formation of just ideas on their extent and relative importance, and to point out the best sources of complete information.

As this plan excludes all long essays and treatises, it necessarily leads to giving more ample space to the separate heads than is done in most Cyclopædias; and in doing this, it is often found difficult to determine the point where the selection of terms must end. This is particularly the case as to names of Persons and Places, which unavoidably form a large part of every book of general reference. It is hardly possible to fix any rule which will not either exclude something that ought to be admitted, or include names of very little importance. Something, therefore, must be left to the judgment of those who contribute to, and superintend, such a publication. It will be observed that the plan of the Cyclopædia has rather been enlarged, since the earlier Numbers, as to the names admitted, and somewhat also, perhaps, in the length of the more important articles. It would appear that, in the proper conduct of such a work, some practice and experience are peculiarly necessary. The difficulty of forming a complete and satisfactory list of words can only be estimated by those who have made the experiment. On looking into the best works of this class already published, it will be found that, while they all differ very considerably as to the words inserted, none are without some omission that would be better supplied. Nor can the Editors of the Penny Cyclopædia congratulate themselves on having inserted *every* term or name that ought to have found a place, though they hope that in the progress of the Work they will be better able to guard against any omission.

As to errors in the articles themselves, either of incorrect statements of facts, or of false deductions from premises, some such are unavoidable in every large work, however carefully the subject-matter has been weighed, or however scrupulously the writer may have discharged his duty. In a periodical publication, in which a number of writers are necessarily combined, and where the matter is almost infinitely varied, the causes of error are still more numerous. The experience of one year, however, enables the Conductors of this Cyclopædia to state with confidence, that whatever errors there may be in the first volume, (and they trust they are neither very nume-ous nor very important,) they feel no doubt that the work in its progress will continue to improve. At least, no exertions will be spared to procure sound information on all subjects, and to convey it in clear and perspicuous language. The Conductors have to express their thanks to numerous correspondents, both for valuable suggestions and criticisms, of which, in many cases, they have been enabled to avail themselves. In some instances, where the accuracy of statements has been called in question, they believe that the Cyclopædia is correct; and in other instances, the difference is no more than may be expected where authorities are at variance, and opinions may naturally be expected to differ somewhat as to their precise value. As most of the communications referred to were anonymous, the Editors have no other means of thanking the writers than by this general acknowledgment.

It may be necessary to mention that a few of the more trifling errors that are most obvious—such as the breaking off of a letter, or a stop at the end of a line—are the unavoidable consequence of the process of stereotyping. Before this process commences, the usual labour of revision is complete; but in producing the stereotype plate new errors are sometimes created. It is the intention of the Conductors of this Work to subject even the stereotype plates to a careful examination, so that injuries of this mechanical nature may be repaired.

In the commencement of their undertaking, the Editors, bearing in mind the difficulty of securing at once an efficient body of contributors, recommended to the Committee only to attempt the publication of Six Numbers in each month. Their present stock of materials, and their reliance upon their numerous coadjutors, founded upon ample experience, have induced them to desire that the work should proceed at a quicker rate. In this they feel satisfied that they only second the wishes of the great body of its purchasers. The work will therefore continue upon the following arrangements:—

1. The *First Volume* of the Penny Cyclopædia—containing Eleven Parts—is now concluded; and will be sold, handsomely bound in cloth, lettered, at Seven Shillings and Sixpence.

2. Commencing with December, 1833, *Two Numbers* of the work will be published *regularly every Week, without Supplements*, so that sometimes Eight, and sometimes Ten Numbers will appear in each calendar month.

3. On the 1st of January, 1834, *Part XII.* will be published, price *Ninepence*, and the *Monthly Parts* regularly continued at that price.

4. On the 1st of September, 1834, the *Second Volume*, containing Eight Ninepenny Parts, will be published, bound uniformly with Vol. I., at Seven Shillings and Sixpence;—and the future volumes will be completed every *Eight* Months.

November 13, 1833

THE PENNY CYCLOPÆDIA

OF

THE SOCIETY FOR THE DIFFUSION OF
USEFUL KNOWLEDGE.

A.

A, the first letter of the alphabet in the English, and many other languages. As a sound, its power in the English language is at least fourfold, as in the words *father*, *call*, *tame*, and *hat*. The first of these sounds is that which generally prevails in other languages. The modified pronunciation of the vowel in *tame* is partly due to the vowel *e* at the end of the word; in *call* and similar forms, the peculiarity arises from the letter *l*; so that the only true sounds of the vowel are perhaps the long sound in *father*, and the short one in *hat*. The printed forms of this letter, viz., the capital A, the small character a, and the italic *a*, are all derived from a common form, differing but slightly from the first of the three. In the old Greek and Latin alphabets, from which our own has descended, the following were the ordinary figures of this letter:—

among which, the fourth and fifth only differ from the rest in the rounding of the angle: the form consisting of straight lines being well adapted for writing on stone, metal, &c.; the rounded letter, on the other hand, being better suited for expeditious writing, with softer or more flexible materials. From this last our two small characters are easily deduced.

A (in music), the sixth note in the diatonic scale, answering to the *la* of the Italians and French. It also stands for the *alto* parts.

A or AN, the indefinite article. Of the two, *an* is used before a vowel. Where the following word begins with a consonant, it being more troublesome to express the final *n*, this letter, from not being pronounced, ceased to be written. Thus we say *an emperor*, but instead of *an king*, we find it more convenient to say *a king*. Sometimes a virtual consonant exists at the beginning of a word without being written, as in *union* and *once*, where the ear catches the initial sounds of *y* and *w*, *younion* and *wunce*. Before such words it is customary to drop the final letter of the article, at least in pronunciation, and there can be no good reason for not writing *a union*, *a once beloved monarch*. On the other hand, whenever *h* is mute, we should retain the *n* both in writing and speaking, thus, *a history*, but *an historical work*. That *an* and not *a* is the primitive form of the article, is proved by the Anglo-Saxon *an*, and the German *ein*; indeed, our own numeral *one* is only another and fuller form of the same word. In such phrases as *three shillings a pound*, the article evidently has this meaning. The double shape of our article has led to a corrupt mode of writing certain words, thus from *an eft* was deduced *a neft*, *a newt*; and the reverse seems to have taken place in the change of *a nadder* to *an adder*. The letter *a* often appears prefixed to nouns so as to constitute a kind of adverb, as *afoot*, *aside*, *aboard*, *now-a-days*, &c. These, as Horne Tooke observes, are all abbreviations of *on fote*, *on syde*, *on borde*, *now-on-daies*, &c., which thus occur in our old English poets. This *on* is an Anglo-Saxon preposition with the meaning of *in*. In many words now in use the *a* in the beginning takes the place of *on*. Alive, for instance, means on life, *i. e.*, in life. 'So he fell asleep,' in the old translation of the New Testament is, *he fell on sleep*.

The *a*, formerly often prefixed to our participles in *ing*, both in the active and passive sense, as *the house is a-preparing*, *he is gone a-walking*, has the same origin.

AA, a small river which flows into the Ems, on the east bank, in the district of Lingen, which is in the kingdom of Hanover. The little town of Freeren stands on the Aa. The singularity of the name, rather than the importance of the river itself, deserves a short notice. *Aa* is possibly a corruption of the word *aue*, which means *green pastures* or *meadows*, and may also have been used to denote the low-flat lands along the banks of the river. *Aue* is the name of a small tributary of the Elbe, and also of a brook in the principality of Schaumbourg-Lippe. *Aue* is also the name of a mountain village, situated in a romantic valley of the Erzgebirg circle of the kingdom of Saxony.

AA, a branch of the Aar, in the canton Aargau; a small river of Jutland; also the name of one of the streams at the confluence of which Breda stands, and the name of a tributary to the Dommel in N. Brabant. The wide diffusion of such a name shows it must have some *general* signification, applicable to all the rivers to which it belongs.

The word *Aa* may be the same as *Aach*, the name of several German rivers, with the guttural *ch* dropped. The Celtic *Ac*, or *Ach*, water, is probably the origin of all these names.

AALBORG, one of the four divisions, and the most northern part, of the peninsula of Jutland, properly so called. It contains about 2820 English square miles, and perhaps about 130,000 inhabitants. The principal town, which is also called Aalborg, stands on the south side of the narrow channel which joins the Liimfiord with the sea, and is a sea-port, with a considerable trade in grain and herrings. From 400 to 500 vessels enter the port annually. The number of inhabitants is about 5300. Aalborg is a bishopric, and has a good academy or cathedral school founded in 1553, with some manufactures of leather, sugar, and tobacco. The name Aalborg means Eel-town, a great number of eels being caught in the neighbourhood: it is in N. lat. 57° 5′, E. long. 10° 5′. All the other towns of the district are small: Thistedt, the next in size, does not contain 2000 inhabitants.

AAR, the principal branch of the Rhine in Switzerland. [See AARGAU.]

Another small stream of the same name falls into the Rhine, in the duchy of Nassau; and a third Aar joins the Rhine in the Prussian province of the Lower Rhine, on the west side, about twelve miles above Bonn.

AARD-VARK (*Orycteropus*, Geoffroy*), in Zoology, a genus of animals belonging to the class *Mammalia*, and order *Edentata*.

In a work, like the PENNY CYCLOPÆDIA, where knowledge is communicated under separate heads arranged in alphabetical order, it is an unavoidable consequence of the general plan that terms must be occasionally employed which have not been previously defined, and of which, in a regular treatise, the explanation would necessarily precede the use. To obviate this inconvenience as much as possible, it is proposed, without entering into the minute details of the subject, or anticipating information which properly belongs to a different part of the work, to give a brief explanation of such terms as they occur; so that the general reader may be enabled to comprehend their meaning and import without the trouble of referring to other sources.

---

* It is usual, in works of Natural History, to place the scientific name of a species after the popular or local name. By the scientific name the species is recognized in every country, while the popular or local name is limited in its use. But as the same species is often called by several scientific names, each of which has been given to it by a different naturalist, it is also usual to place the name of the naturalist after the word which he has invented or adopted. Thus, Aard-vark is the Dutch name of the animal in question; Orycteropus the scientific name by which it is commonly known; and Geoffroy St. Hilaire (generally abridged Geof.) the name of the naturalist who gave it that scientific denomination.

Before commencing the history and description of the genus which more properly constitutes the subject of the present article, we shall, therefore, give a short explanation of the terms *Mammalia* and *Edentata*, as well as of the technical import of the words *Class*, *Order*, *Genus*, and *Species*, which are of constant occurrence in Zoology: these terms would otherwise be obscure or unintelligible to an ordinary reader.

The word Mammal (Mammalia is the Latin form of the plural) was formed by Linnæus from the Latin mamma, signifying a breast or udder, in the same manner as our common word animal is formed from anima, life or soul; and was intended to denote those animals which suckle their young, and for which there is no generic name in any known language sufficiently definite and comprehensive. The common word Quadruped, which more nearly expresses the exact idea than any other, has no relation to the natural affinities which we observe among animals, since it excludes man and the cetaceous tribes (such as whales), at the same time that it comprehends the lizards, tortoises, and other reptiles, which have but a very remote analogy to the true Mammalia.

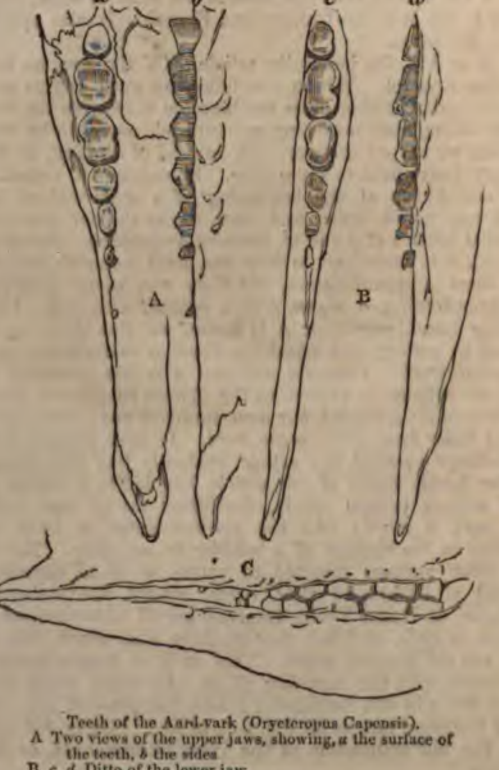
The vernacular term Beast, which we often use in opposition to Birds and Fishes, is still more vague and indeterminate. The word Mammal, however, so happily imagined by the great Swedish naturalist, is liable to none of these objections, but expresses, in a distinct and definite manner, the most prominent functions and natural limits of this class of animals. In the constant use which we shall be obliged to make of this term, we shall adopt the common English form of the plural, *Mammals*, instead of the Latin form, *Mammalia*, though the latter is most generally used by British zoologists. The word *Mammals* is as regularly formed, and therefore as admissible into the English language, as animal and animals.

Mammals, therefore, in the technical language of zoologists, constitute a *class*, or primary division of the animal *kingdom;* and are, in this respect, co-ordinate with Birds, Fishes, Reptiles, and Insects; all of which are so many *Classes*. The term *Order* denotes a subordinate division, and bears the same relation to a class which this latter does to a kingdom; so that a class is made up of orders, in the same manner as a kingdom is made up of classes. The next inferior sub-division to an order is a *Genus;* and this is itself composed of *Species*, the lowest link in the chain of scientific classification, and that which admits of no further division. A species, then, comprehends all those animals which may reasonably be supposed to be descended from one common, original stock; and in this sense all men compose but a single species, all horses compose but a single species; and in the same manner all oxen, sheep, goats, dogs, &c. compose respective and appropriate species. Difference of climate, variety of food, and other local and extraneous circumstances, undoubtedly produce striking changes in the form, size, and colour of different individuals, even of the same species; examples of which are sufficiently abundant among all domestic animals, and that, too, in exact proportion to the degree of their domestication, and to the care and attention which have been bestowed upon them by man. But these variations are confined within certain prescribed limits, and the utmost power and ingenuity of man have been exerted in vain to produce and perpetuate a new race or species of animals. He has succeeded, to be sure, in procuring the Mule from the intercourse of the Horse and the Ass, two very distinct species, though in some respects closely allied to one another; but this mule is itself a barren, unproductive being, which Nature regards as a monster, and to which she has denied the power of continuing its race.

An example will best illustrate the true import of the ms which we have been here endeavouring to explain. us the dog, the fox, the wolf, and the jackal, are all so ny *species* of one common *genus;* as are likewise the lion, the tiger, the panther, the lynx, and the common cat, species of another genus. These are respectively called the genus *Canis*, or the dog kind, and the genus *Felis*, or the cat kind; and compose, together with the hyænas, civets, weasels, bears, badgers, &c. the natural *Order* of *Carnivora*, or flesh eaters, which have six incisor or front teeth in each jaw, and live upon the flesh of other animals. Another natural order of Mammals comprises all those which, like the rat, the squirrel, the rabbit, and the guinea-pig, have only two large teeth in front, which they continually employ in gnawing whatever falls in their way; they are, therefore, called Rodentia, or gnawers. These, at least in the number of their incisor teeth, form the intermediate link which connects the Carnivora with the Edentata, or next order of Mammals, which are distinguished by having no front teeth at all, and are therefore constrained to live entirely upon a vegetable regimen, or upon insects, carrion, and other soft substances which require little cutting or mastication. These different Orders of Carnivora, Rodentia, and Edentata, together with the Ruminantia or ruminating animals, the Cetacea or whale kind, and others less important, which it is unnecessary here to enumerate, compose the *class* Mammalia.

Having thus briefly explained the signification of those technical terms which will occur most frequently in the subsequent Zoological articles, we shall return from this digression to the more immediate object of our present consideration.

The Orycteropus is now separated from the Myrmecophaga, or Anteaters of Linnæus, with which it had been formerly associated. In its anatomical structure, it bears a much closer relation to the armadillos than to any other quadrupeds, not even excepting the ant-eaters, with which it was formerly associated. Like these animals, the orycteropus has neither incisors nor canine teeth; and its feet are equally provided with large and powerful claws, for digging up roots and insects, and for forming subterraneous burrows. Its molar teeth, however, are altogether peculiar both in form and structure, and have no resemblance to the teeth of any other known animal. Of these there are five large ones on each side (both in the upper and under jaws), which are always permanent; and a variable number of from one to three smaller ones, placed in front of the others, and apparently representing the false molars of ordinary quadrupeds. The first of the large molars is smaller than any of the other four, and of a cylindrical form, somewhat compressed or flattened on the sides; the second is rounder; the third and



Teeth of the Aard-vark (Orycteropus Capensis).

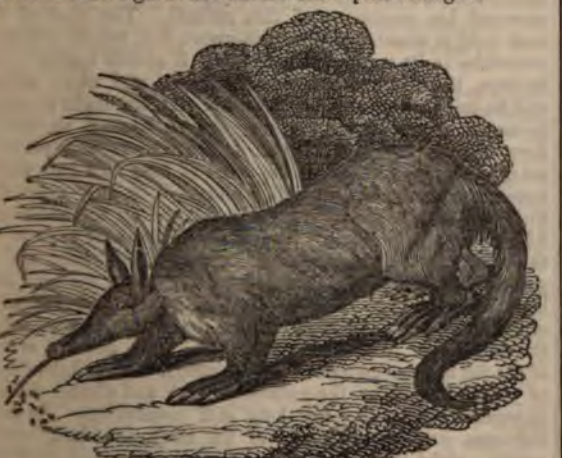
B, *c*, *d*, Ditto of the lower jaw.
C The teeth in their natural position,

fourth are each composed of two similar cylinders, as it were, soldered together, and the last is a simple cylinder, like the first and second. Immediately in front of these are the small or false molars, which, being of a deciduous nature (falling annually), vary in number according to the individual. In their internal structure these teeth differ from those of all other animals. They are pierced throughout their whole length with an infinite number of small capillary tubes, running in the same longitudinal direction, and opening at the root or under part of the teeth. The crowns or upper surfaces of the teeth are covered with enamel, but after this has been worn away by the continued process of mastication, as in very old animals, the openings of these small canals may be plainly distinguished upon the surface also; and in this state, the teeth, to use the appropriate comparison of Baron Cuvier, resemble the joint of a cane cut across, and exhibiting the numerous minute vessels which perforate its interior. Properly speaking, these teeth are destitute of real roots, and are therefore, like the tusks of the elephant, and the incisors of the rodentia, capable of being indefinitely increased, by the deposit of new matter on the under extremity, to counterbalance the continual wear of the upper surface.

In the form of the extremities the orycteropus resembles the armadillos still more nearly than in the nature of its dental system. The legs are remarkably short and stout; the feet plantigrade (that is to say, the animal walks upon the whole sole of the foot, as man and the bear, instead of bringing the point of the toe only in contact with the ground, as may be observed in the dog, horse, &c.); and the toes, of which there are four on the fore feet and five on the hind, are armed with extremely large, powerful claws, flattened horizontally, and scooped or hollowed out on the under surface, so as to form a most efficient instrument for digging and burrowing beneath the surface of the earth. This process is still further facilitated by the oblique form of the anterior extremities, arising from the unequal length of the toes; the two interior being considerably longer than the others, and the whole diminishing gradually from the index (or toe corresponding with the fore-finger) outwards. In other parts of its anatomy the orycteropus resembles both the armadillos and the ant-eaters, and particularly in the form and structure of the stomach and alimentary canal. The reader who is desirous of further information upon these subjects may consult Cuvier's *Leçons d'Anatomie Comparée*, and his great work *Sur les Ossemens Fossiles*, from which the details here given are for the most part abridged.



The only species of this curious genus with which zoologists are at present acquainted is the *Aard-Vark* (Orycteropus Capensis), called *innagu* by the Korah Caffres, and *goup* by the Hottentots. It is an animal extremely common in some parts of Southern Africa, though, from its nocturnal habits and extreme timidity, it is not so frequently seen as many others which are in reality scarcer. Its colonial name of aard-vark, or earth-pig, by which it is known among the Dutch inhabitants of the Cape of Good Hope, is derived as well from its habit of burrowing as from the general appearance which it bears, at first sight, to a small, short-legged pig. This animal, when full grown, measures about three feet five inches from the snout to the origin of the tail; the head is eleven inches long; the ears six inches; and the tail one foot nine inches. The head is long and attenuated; the upper jaw projects beyond the lower, and ends, as in the common hog, in a truncated, callous snout, having the nostrils pierced in the end of it; the mouth is small for the size of the animal, and the tongue flat and slender, not cylindrical as in the true ant-eaters, nor capable of being protruded to such an extent as in these animals: it is, however, covered in like manner with a viscous or glutinous saliva, which firmly retains the ants upon which the animal lives, and prevents those which once come into contact with it from escaping afterwards. The ears are large, erect, and pointed; and the eyes, which are of moderate size, are situated between them and the snout, about two-thirds of the distance from the extremity of the latter. The body of the aard-vark is thick and corpulent; the limbs short and remarkably strong; the hide thick, tough, and nearly naked, having only a few stiff hairs, of a pale reddish-brown colour, thinly scattered over it, excepting on the hips and thighs, where they are more numerous than elsewhere. The tail is about half the length of the body and head together, and, like the body, is nearly naked; it is extremely thick and cylindrical at the base, but decreases gradually towards the extremity, and ends in a sharp point.

Thus formed, the aard-vark is in all respects admirably fitted for the station which Nature has assigned to it in the grand economy of the animal kingdom. It feeds entirely upon ants, and in this respect fulfils the same purpose in Southern Africa which is executed by the pangolins in Asia, the myrmecophaga in America, and the echidna in New Holland. To those who are only acquainted with the size and nature of these insects in the cold northern climates of Europe and America, it may seem surprising how an animal so large as the aard-vark can support itself exclusively upon ants, and yet be invariably found fat and in good condition. But the ants and termites of tropical countries are infinitely more numerous than those which inhabit more northern latitudes, and so large as sometimes to measure an inch or an inch and a half in length. The bodies of these ants are, besides, of a soft, unctuous nature; and travellers inform us that the Hottentots themselves frequently collect them for food, and even prefer them to most other descriptions of meat. Patterson affirms that prejudice alone prevents the Europeans from making a similar use of them; and says that, in his different journeys, he was often under the necessity of eating them, and found them far from disagreeable. However this may be, their importance in fattening poultry is well understood at the Cape, and the farmers collect them by bushels for this purpose.

These insects raise mounds of an elliptical figure to the height of three or four feet above the surface of the ground; and so numerous are these gigantic ant-hills in some parts of Southern Africa, that they are frequently seen extending over the plains as far as the eye can reach, and so close together that the traveller's waggon can with difficulty pass between them. They abound more especially in the Zeurevelden, or sour districts, so called from producing a kind of sour grass; are seldom found on the karroos or downs, and never in very dry or woody districts. By constant exposure to the rays of a powerful tropical sun they become so hard and indurated on the outer surface that they easily support the weight of three or four men, and even a loaded waggon will sometimes pass over without crushing them. Internally these mounds are of a spongy structure, something resembling a honeycomb, and are so completely saturated with animal oil that they inflame without difficulty, and are an excellent substitute for wood or coal.

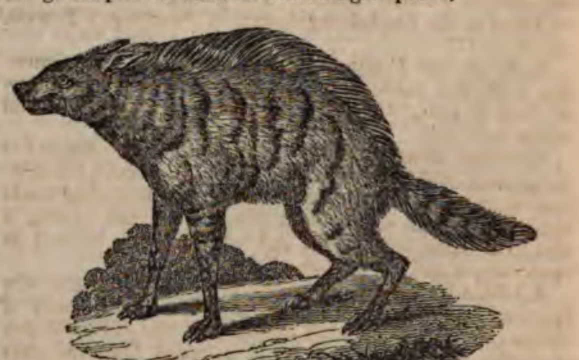
Wherever ant-hills abound the aard-vark is sure to be found at no great distance. He constructs a deep burrow in the immediate vicinity of his food, and changes his residence only after he has exhausted his resources. The facility with which he burrows beneath the surface of the earth is said to be almost inconceivable. We have already seen how admirably his feet and claws are adapted to this purpose; and travellers inform us that it is quite impracticable to dig him out, as he can in a few minutes bury himself at a depth far beyond the reach of his pursuers; and, further, that his strength is so great as to require the united efforts of two or three men to drag him from his hole. When fairly caught, however, he is by no means retentive of life, but is easily dispatched by a slight blow over the snout. The aard-vark is an extremely timid, harmless animal, seldom removes to any great distance from his burrow, being slow of foot and a bad runner, and is never by any chance found abroad during the day-time. On the approach of night he sallies forth in search of food, and, repairing to the nearest inhabited ant-hill, scratches a hole in the side of it just sufficient to admit his long snout. Here, after having previously ascertained that there is no danger of interruption, he lies down, and, inserting his long slender tongue into the breach, entraps the ants, which, like those of our own country, fly to defend their dwellings upon the first alarm, and, mounting upon the tongue of the aard-vark, get entangled in the glutinous saliva, and are swallowed by whole scores at a time. If uninterrupted, he continues this process till he has satisfied his appetite; but on the slightest alarm he makes a precipitate retreat, and seeks security at the bottom of his subterranean dwelling. Hence it is that these animals are seldom seen even in those parts of the country in which they are most numerous. Like other nocturnal animals, which pass the greater part of their lives in sleeping and eating, they become exceedingly fat, and their flesh is considered to be a wholesome and palatable food. The hind-quarters, particularly when cut into hams and dried, are held in great esteem, and are much sought after by colonial epicures.

AARD-WOLF (*Proteles*, Is. Geof.), in Zoology, a genus of digitigrade carnivorous mammals founded by M. Isidore Geoffroy St. Hilaire for the purpose of giving a place to a new and singular quadruped brought from the interior of Caffraria by the late traveller Delalande. The three specimens of this interesting animal procured by M. Delalande were all, unfortunately, of an immature age, and had not acquired their permanent teeth, so that the characters of their adult dentition still remain to be determined. Enough, however, is known to enable us to assign the most prominent and influential characters of the genus, and to infer, with a tolerable degree of accuracy, the habits and economy of the animal.

It is an observation at least as old as Pliny, that Africa is a land of wonders, which continually produces a succession of new and singular objects. In zoology, the maxim of the Roman philosopher, as to African wonders, is verified almost daily. Among the most recent examples of this fact we may adduce the discovery of the *proteles;* an acquisition of peculiar interest to the zoologist, as forming the intermediate link which connects the civets with the dogs and hyænas, three genera which have hitherto stood, as it were, insulated from surrounding groups, and widely separated from one another. The dogs and hyænas, indeed, had been united a short time previous by the discovery of an intermediate species in the same locality which has since produced the proteles; but it is this latter species alone, which, uniting the characters of all these three genera, enables us to trace their natural affinities, and to assign to them their proper position in the scale of existence.

To the external appearance and osteological (bony) structure of a hyæna, this truly singular animal unites the head and feet of a fox, and the teeth and intestines of a civet. It has five toes on the fore feet, and four only on the hind; the innermost toe of the fore foot is placed, as in the dogs, at some distance above the others, and therefore never touch the ground when the animal stands or walks. The legs also are completely digitigrade; that is to say, the heel is elevated, and does not come into contact with the surface, as in man and other similarly formed animals which walk upon the whole sole of the foot, and are thence said to be plantigrade. It is of great importance to remark the difference between these two modifications of the locomotive organs, because they have a very decided and extraordinary influence upon the habits and economy of animal life. Digitigrade animals, which tread only upon the toes and carry the heel considerably elevated above the ground, have much longer legs than plantigrade animals, and are therefore especially fitted for leaping and running with great ease and rapidity. Accordingly, it will be observed that the horse, the stag, the antelope, the dog, and other animals remarkable for rapidity of course, partake strongly of this formation; and even their degree of swiftness is accurately measured by the comparative elevation of the heel. Inattentive observers sometimes misapprehend the nature of this peculiar conformation of the extremities of digitigrade animals, and are apt to confound the hough with the ankle, and to mistake for the knee what is really the heel of the animal. Thus we have heard it said that, in the hind legs of the horse, the knee was bent in a contrary direction to that of man. This is by no means true: a little attention to the succession of the different joints and articulations will show that what is called the cannon-bone in the horse, and other digitigrade animals, in reality corresponds to the instep in man, and that what is generally mistaken for the knee really represents the heel.

In the particular case of the proteles the natural effect of the digitigrade formation is, in some degree, lessened by the peculiar structure of the fore legs, which, contrary to the general rule observable in most other animals, are considerably longer than the hind. In this respect, also, the proteles resembles the hyænas; and in both genera this singular disproportion between the anterior and posterior extremities abridges the velocity properly due to their digitigrade conformation. It has been already observed that the only individuals of this genus which have been hitherto properly observed were young specimens, which had not acquired their adult dentition; but it was sufficiently obvious to the experienced eye of M. Cuvier, who first examined them, that the dental system of the mature animal must very closely resemble, if it be not actually identical with, that of the civets and genets. The young animal presented three small false molars and one tuberculous tooth on each side both of the upper and under jaws; and we shall find, in the sequel, that the approximation of M. Cuvier is fully justified by the evidence of another accurate observer, who had an opportunity of examining this animal in its native regions. The genus proteles contains but a single species, the *Aard-wolf*, or earth-wolf (*Proteles cristata*), so called by the European colonists in the neighbourhood of Algoa Bay, in South Africa, the locality in which M. Delalande procured his specimens of this animal. The size of the aard-wolf is about that of a full-grown fox, which it further resembles in its pointed muzzle; but it stands higher upon its legs, its ears are considerably larger and more naked, and its tail shorter and not so bushy. At first sight it might be easily mistaken for a young striped hyæna, so closely does it resemble that animal in the colours and peculiar markings of its fur, and in the mane of long stiff hair which runs along the neck and back: indeed, it is only to be distinguished by its more pointed head, and by the additional fifth toe of the fore feet. The fur is of a woolly texture on the sides and belly, but a mane of coarse, stiff hair, six or seven inches in length, passes along the nape of the neck and back, from the occiput to the origin of the tail, and is capable of being erected or bristled up, like that of the hyæna, when the animal is irritated or provoked. The general colour of the fur is pale cinereous (ash-coloured), with a slight shade of yellowish-brown: the muzzle is black and almost naked, or covered only with a few long stiff moustaches. Around the eyes, and on each side of the neck, are dark brown marks; eight or ten bands of the same colour pass over the body in a transverse direction, exactly as in the common striped hyæna; and the arms and thighs are likewise marked with similar transverse stripes. The legs and feet are an uniform dark brown in front, and grey behind. The long hairs of the mane are grey, with two broad rings of black, the second of which occupies the point; those of the tail are similarly marked, and equally long and stiff; whence it appears as if the mane and tail were clouded with an alternate mixture of black and grey. The ears are grey on the interior, and dark brown on the outer, surface.



In its habits and manners the aard-wolf resembles the fox: like that animal it is nocturnal, and constructs a subterraneous burrow, at the bottom of which it lies concealed during the day-time, and only ventures abroad on the approach of night to search for food and satisfy the other calls of nature. It is fond of the society of its own species; at least, many individuals have been found residing together in the same burrow; and, as they are of a timid and wary character, they have generally three or four different entrances to their holes, so that if attacked on one side they may secure a retreat in an opposite direction. Notwithstanding the disproportionate length of their fore legs they are said to run very fast; and so strong is their propensity to burrow, that one of M. Delalande's specimens, perceiving itself about to be run down and captured, immediately ceased its flight, and began to scratch up the ground, as if with the intention of making a new earth.

M. Isidore Geoffroy St. Hilaire, in his paper on the Proteles, inserted in the eleventh volume of the *Mémoires du Muséum*, has bestowed upon this species the name of *Proteles Lalandii*. He has done so, in the belief that the species has not been indicated by any previous traveller. We have considered it proper, however, to substitute the specific name of *Proteles Cristata*, for that proposed in honour of M. Lalande, for both Sparrman and Levaillant have mentioned the aard-wolf long before the date of M. Delalande's journey; and the former has not only described it with tolerable accuracy, but has even ascertained its true generic characters, and associated it with the civets, under the denomination of *Viverra cristata*. The passage alluded to will be found in the English translation of *Sparrman's Travels*, vol. ii., p. 177.

In the *Second Voyage* of Levaillant, vol. ii., p. 360, mention is likewise made of this animal under the appellation of 'loup de terre,' which is a simple translation of its colonial name aard-wolf.

Sparrman mentions having found ants in the stomach of the proteles, and these, it may be observed, are also a favourite food of the bear. The dental system of this animal would further lead us to suppose that, like the fox and hyæna, it also feeds upon wild grapes and bulbous roots, as well as upon carrion and the produce of the chase.

AARGAU, one of the twenty-two Swiss cantons. On the north the Rhine separates it from the grand duchy of Baden: the canton of Basel bounds it on the west, and that of Zürich on the east. It takes its name from the river Aar, which rises in the glaciers that form the southern limits of the canton of Bern; and, after flowing through the lakes of Brienz and Thun, and past the towns of Bern, Soleure, and Aarau, falls into the Rhine on the south bank, about fourteen miles above Laufenburg. The whole length of its course is about 160 miles. The canton takes its name from the river, the word *Aar-gau* signifying the *province* or *district* of the Aar: the same termination frequently occurs in other names, such as Thurgau.

The canton of Aargau is a pleasant, and in many parts a fertile, district, diversified by hills, mountains, and valleys. The chain of the Jura mountains runs through part of the canton, but they hardly attain the height of 3000 feet. The number of inhabitants is about 152,900. Aargau is one of the most industrious cantons of Switzerland, and perhaps more a manufacturing than agricultural country. This canton has paid great attention to the education of its people. The chief town is Aarau, which contains 4000 inhabitants; and has manufactures of silk, cotton, and leather; and good establishments for education. At Laufenburg are some falls in the Rhine, which impede the navigation of the river. A bridge here leads over the Rhine to the little village of Laufenburg, in Baden. Aargau contains many neat, industrious towns; such as Zofingen with a good library, Lenzburg, Klingnau, Schinznach having near it the castle of Hapsburg, which is the original seat of the Imperial Austrian family, and Baden, which has warm baths, and a good Lyceum. Each of the eight districts into which Aargau is divided has a secondary school. [See *Journ. of Educ.*, No. 6.] The area of the canton is estimated at about 770 English square miles, in Hassel's Statistics.

AARHUUS, a division of Jutland, containing 1800 English square miles, and 88,000 inhabitants; with a considerable portion of good soil. Aarhuus, the chief town, stands in N. lat. 56° 10′, E. long. 10° 22′, between the sea and a small lake, which, at its outlet, forms a port. The town is pretty well built, and contains a large cathedral church: the manufactures are cotton and woollen cloth, gloves, sugar-refining to a small amount, tobacco, and leather. The number of inhabitants is about 6000. Aarhuus is the point in Jutland from which passengers generally set out to the island of Zealand, where they land at a place called Kallundborg, whence a road leads to Copenhagen. Aarhuus is about 100 miles W. N. W. from the capital. Randers, N. N. W. of the town of Aarhuus, on the Guden, a small navigable river, has about 5000 inhabitants, whose branches of industry are similar to those of Aarhuus, with the addition of stockings and brandy-distilleries. Randers has a grammar-school and good hospital.

AARON, the first high-priest of the Jews. He was the elder brother of Moses, and was, by the express appointment of Heaven, associated with that illustrious legislator in the enterprize of delivering their countrymen from Egyptian bondage, and conducting tnem to the promised land. Aaron, who was a ready and eloquent speaker, was the chief instrument employed in announcing the command of God to Pharaoh, and attesting it by the series of stupendous miracles recorded in the earlier chapters of the book of Exodus. After the passage of the Red Sea, and during the sojourn in the wilderness, he was far from manifesting the steady confidence and undaunted disregard of popular clamour which characterized the conduct of his brother: but, notwithstanding the timidity and weakness which he had shown in yielding to the demand of the impatient and superstitious multitude, that he would make them a golden calf to worship, he was, in conformity to the divine purpose, consecrated to the priesthood, of which the highest office was made hereditary in his family. Aaron, however, was not permitted to reach the promised land, any more than his brother Moses. Having ascended the summit of Mount Hor, in company with Moses and his eldest son Eleazar, he died there, after Moses, as commanded by God, had stripped him of his sacerdotal robes, and put them upon his son. This event happened when Aaron was in the hundred and third year of his age, forty years after the departure of the Israelites from Egypt, and, according to the commonly received chronology, in the year 1451 B. C., or 2553 from the creation of the world.—The history of Aaron is to be found in the book of Exodus, and the three following books of the Pentateuch.

AARON, the fifth caliph of the race of the Abassides, born 765, died in 802.—[See ABASSIDES.]

AB, the fifth month of the ancient Hebrew year, but now the eleventh (or, in intercalary years, the twelfth), in consequence of the transfer of the new year from spring to autumn.

On the 1st day of Ab a fast is held in commemoration of the death of Aaron. On the 9th a very solemn fast is observed in remembrance of the destruction of the Holy Temple by Nebuchadnezzar in 588, B. C., and of the destruction of the second Temple by Titus, A. D. 70. This fast is considered the most mournful of the whole year: on this day, in the synagogues, the lamentations of Jeremiah are publicly read, with other portions of the Bible, expressive of sorrow and desolation. No recreation is allowed from the beginning of the month, nor may any man shave his beard. the more serious Jews even abstain from all meat, except on the Sabbath-day. On the 18th, another fast is observed. All these fasts are postponed one day if they fall on the Saturday.

A little festival is celebrated on the 15th day of the month to commemorate an ancient custom, according to which, the young girls of each tribe came forth into the fields clothed in white, and exhibited themselves in dances before the marriageable young men, with the view of being selected by them in marriage. This festival is called Tub-ab, or the fifteenth Ab, the word Tub expressing the characters T and B, or 6 and 9, used by the Jews for fifteen.

The month of Ab may begin in some years as early as the 10th July, in others as late as the 7th August. In 1833, it commences on the 17th July.

Ab is the name of the twelfth month of the Syrian year coinciding with our August.

ABABDE, the name of several African tribes, which occupy the country between the Nile and the Red Sea, south of Kosseir, nearly as far as the latitude of Derr, 22°. 47′. The Bisharye inhabit the mountains from thence southwards. Many of the Ababde have settled in Upper Egypt, on the east bank of the Nile, from Kenneh to Assouan, and thence to Derr. According to Belzoni, some of them are spread as far as Suez. But the greater part still live like Bedouins, and act as guides to the Sennaar caravans which set out from Daraou, a place about ten hours' journey north of Assouan. The Ababde formerly guarded the caravans from Kenneh to Kosseir, on the Red Sea;

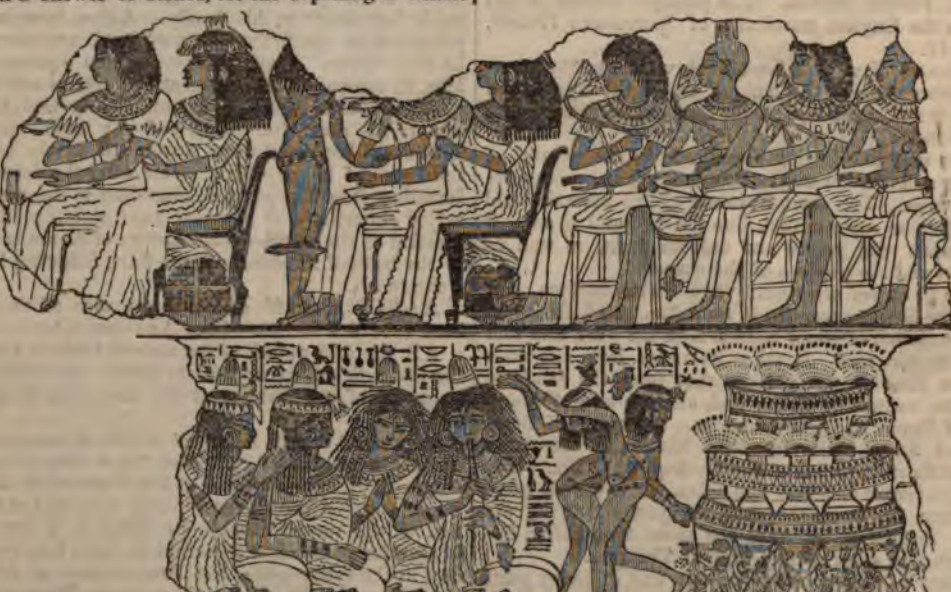
but they have been deprived of this branch of profit by the Maazu and Ataony Arabs, who live to the north, and farm the profits of this line of road from the Pasha.

The Ababde have considerable property, but a very bad character; they are described as faithless, and unworthy of the Bedouin origin of which they boast.

These people are known in Upper Egypt for their excellent camels, and particularly for their dromedaries. They trade principally in senna leaves, and charcoal made of acacia wood, which is sent as far as Cairo. The Ababde have few horses; they fight with other Arab tribes upon camels. Their arms are a target, lance, and sword. They are divided into three principal tribes, El Fokara, El Ashabat, and El Meleykab.

Those who encamp with the Bisharye speak the language of the latter. The female children of the Ababde and Jaafere Arabs, as Burckhardt calls them, who inhabit the west bank of the Nile, south of Thebes, as far as the first cataracts, as well as the female children of all the people south of Kenneh and Esne to the borders of Sennaar, undergo the operation of excision, which was an old Egyptian custom. [Compare Strabo., p. 824, Casaub.] The Ababde fight naked, except that they have a rag or napkin round their waists. A fight which Burckhardt saw commenced with a shower of stones, for the repelling of which missiles, their targets appeared very useful. The combatants on each side were about thirty; and the results were, three men slightly wounded, and one shield cleft in two.

This account is from Burckhardt's *Travels in Nubia* (London, 1819), who appears, from this and other passages, to consider the Ababde as of Arab stock; but if this be his meaning, it seems to be incorrect. Other writers say that the Ababde, who are of the same family as their southern neighbours, the Bisharye, differ in appearance, habits and language from the Arabs. The latter fact might readily be established by a comparison of an Arabic and Ababde vocabulary; but we have not been able to find one of the latter language. That the Ababde have, at different periods, mixed with the Arabs is certain, and we believe have got their religion, such as it is, from the same nation. Their form, which is not that of the negro, their dark colour, and their long hair besmeared with grease, and hanging in ringlets, which have been compared in shape to corkscrews, show them to be of Nubian stock, and probably the remnant of a race long settled in these regions. The kind of head-dress which they wear is often seen on the Egyptian monuments, and a pretty correct notion of it may be formed from the following Egyptian painting, now in the British Museum.



The fact of the Ababde being camel-breeders, and using them in battle, coincides singularly with the habits of the *Arabians*, as Herodotus calls them, who lived south of Egypt, and were in the army of Xerxes when he invaded Greece, B.C. 480.

It is conjectured by Ritter, that the Ababde, as well as the Bisharye, may be a remnant of that people, whom we hear of under the Roman Emperors by the name of Blemyes. We hear no more of the Blemyes after the Arab conquest of Egypt, but they appear under the general name of Bejas, as the great carriers between the Nile and Aidab on the Red Sea, and, in fact, as a commercial people. The Bisharye, the Ababde, Barabras, &c., may be considered as different branches of the Beja stock. [See Bejas.] What reasons Herodotus had for calling the camel-riding people south of Egypt by the name of Arabs, it is difficult to say; only we may observe, that Arabia, properly so called, was then very little known; and the word Arabs would be applied vaguely, and perhaps sometimes incorrectly, to many people, who lived a nomadic life. For many Ababde customs, see Belzoni's *Researches*, p. 309, 4to. [See Ritter's *Geography*, Africa.]

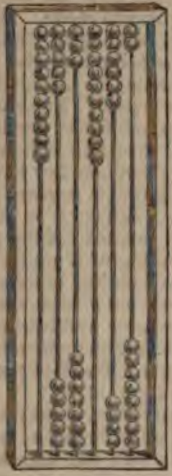
ABACISCUS, in architecture, is a diminution of the architectural term Abacus, and is principally applied, when used at all, which is not often, to the tiles or squares of a tessellated pavement.

A'BACUS, in architecture, is the level tablet, whether square or oblong, which is almost always formed on the moulded or otherwise enriched capital of a column, to support the horizontal entablature. [See the words Capital, Column, and Entablature.] The architectural application of the term Abacus, which in the original is applied to any rectangular tile-like figure, arises from a story which Vitruvius tells of the manner in which the foliated capital called the Corinthian originated.

A'BACUS, a game among the Romans; so called from its being played on a board, somewhat in the manner of chess.

A'BACUS, an instrument employed to facilitate arithmetical calculations. The name may be given with propriety to any machine for reckoning with counters, beads, &c., in which one line is made to stand for units, another for tens, and so on. We have here given the form of an abacus, such as we may recommend, for the purpose of teaching the first principles of arithmetic, the only use, as far as we know, to which such an instrument is put in this country. Its length should be about three times its breadth. It consists of a frame, traversed by stiff wires, on which beads or counters are strung so as to move easily. The beads on the first right hand row are units, those on the next tens, and so on. Thus, as it stands, the number 57048 is represented upon the lower part of it.

For a more detailed account of the method of using this instrument for the purposes of instruction, see Numeration. There is an instrument sold in the toy-shops with twelve wires, and twelve beads on each wire, for teaching the multiplication-table, which may be made of more use if applied according to the method which will be described in the article referred to.



The abacus can never be much used in this country, owing to our various division of weights and measures. We should need one abacus for pounds, shillings, and pence; another for avoirdupois weight; a third for troy weight, and so on. In China, however, where the whole system is decimal, that is, where every measure, weight, &c., is the tenth part of the next greater one, this instrument, called in Chinese Shwanpan, is very much used, and with most astonishing rapidity. It is said that while one man reads over rapidly a number of sums of money, another can add them so as to give the total as soon as the first has done reading. Their abacus differs from the one described above, in having only five beads on each wire, one of which is distinguished from the rest either in colour or size, and stands for five. There is one of these instruments in the East India Company's Museum. The Greeks and Romans used the same sort of abacus, at least in later times. The Russians are also much in the habit of performing calculations by strings of beads. It is probable that the word was originally applied to a board strewed with dust or sand, on which letters were marked in teaching children to read. The word *Abax* was the Greek term for this instrument. Some etymologists derive the name from the Phœnician *Abak*, which signifies dust. Lucas de Burgo, an old algebraical writer, says it is a contraction of Arabicus. It is most probable, however, that the first derivation is correct. A chequered board, such as we still sometimes see at the doors of public-houses, was formerly used in this country as an abacus [see EXCHEQUER], and a chess-board would now do very well for the purposes of instruction above-mentioned. The multiplication-table is sometimes called the Pythagorean abacus.

ABANDONMENT is a term used in marine insurance. Before a person, who insures a ship or goods, can demand from an insurer or underwriter the stipulated compensation for a total loss of such ship or goods, he must *abandon* or relinquish to the insurer all his interest in any part of the property which may be saved. [See INSURANCE.]

ABA'NO, PETER DE, a celebrated Italian physician and philosopher of the middle ages. He was born in 1250 at Abano, anciently Aponus, a village about five miles from Padua. Peter de Abano, or Apono as he is often called, having repaired to the University of Paris to complete his education, is said, while studying there, to have published the most famous of his works—his *Conciliator Differentiarum Philosophorum et Medicorum*, a performance from which he has derived the title of the *Conciliator*. He afterwards wrote various other works which are less known, and also translated into Latin some of the treatises of the Arabian physicians. Abano was undoubtedly one of the most accomplished scholars and men of science of his age; and he also seems to have been possessed of native powers and an inventive genius. As it was, he has been regarded as one of the principal restorers of true science in his native country. After he left the University of Paris, where he took the degree of Doctor both in Philosophy and in Medicine, he settled at Bologna, where he practised as a physician for the remainder of his life. Abano was also a great proficient in mathematics and astronomy, so far as those sciences were known in that age. His reputed skill in this kind of learning caused him to be regarded, in his own day, as a magician; and, in his latter years, a process was actually commenced against him as such by the Inquisition. An inscription on a statue which the citizens of Padua erected to him after his death, asserts that he was suspected of magic and accused of heresy, but acquitted. Other authorities, however, assure us that he only escaped condemnation by his death, in 1316, at the age of sixty-six; and that the sentence, which would have been passed upon him if he had lived, was executed upon his effigy in straw. The imputation of being a practiser of magic long clung to the memory of Abano in the popular belief, and even in the minds of many of the learned. As one of the many distinguished cultivators of mathematical and physical science who have acquired this sort of celebrity, he occupies a conspicuous place in the curious work which the French physician, Gabriel Naudé, published in the early part of the seventeenth century, entitled *A Vindication of the Great Men who have been accused of Magic*. Abano, however, although no student of magic, shared the universal belief of that and several succeeding ages in the delusions of astrology, and had no doubt that the movements of the stars exercised the most important influence on human affairs. The calculation of these imaginary sympathies formed, indeed, the principal part of his astronomy. The mysterious and almost prophetic character which he and others thus professed to derive from their scientific skill, must no doubt have helped, in a considerable degree, to countenance and confirm the popular notion of their intercourse with the powers of darkness. [See *Bayle's Dictionary*—Abano.]

ABATEMENT. This word is derived from the old French word *abater*, which signified to beat down, prostrate, or destroy.

Before entering upon the explanation of the present meaning of this term, it will be well to observe, for the information of those who may not be acquainted with the history of our law, that by far the greater number of the terms of art (as they may be called) peculiar to it, are derived either from the Norman-French, or the Latin,—we shall therefore give a cursory view of the circumstances which led to their adoption. When William I., commonly styled the Conqueror, became King of England, he filled all the posts of profit and honour with subjects from his Norman dominions —the civil places chiefly with ecclesiastics. The foreign priests having obtained from their master all the seals of the judges and other officers of the superior courts of justice, it was found necessary to ordain that all proceedings in them should be carried on in the Norman tongue instead of the English, with which these new judges were for the most part altogether ignorant. This practice continued until Edward III. conquered the armies of the French in their own country, and abolished the use of their language in the courts of justice here. At the same time that all arguments and judgments of law were spoken in French, the written parts of the proceedings, such as the writs and records, were all in the Latin language, with which the priests of the Roman Church were necessarily more or less acquainted. The judicial *writings* continued to be in Latin long after Edward III. had expelled the French tongue from our courts; and they were not written in our own language until the reign of George II., when an Act of Parliament was passed for the purpose.

It will be evident that, under the circumstances described, the more ancient legal terms would, whenever that could conveniently be done, be translated into the French and Latin languages; and as, during the periods mentioned above, the laws of England experienced great alterations and received many additions, abundance of new terms were necessarily called for to express new notions, and were naturally drawn from the languages then in legal use. Many of the expressions thus translated, and those first invented, are employed at the present day with little or no alteration. Of this we have an example in the word which is the subject of this article.

The term *Abatement* is used by our law in three senses viz. those of abating a nuisance, abating an action or indictment, and abating into a freehold.

The first of these, in which the word seems to be used in its primitive or literal sense, is that of abating or *beating down* a nuisance; an expression commonly used, and, therefore, well understood. Whatever unlawfully annoys, or does damage to another, is a nuisance, which he is at liberty to abate, that is beat down, and remove; provided in so doing he commits no breach of the peace, and does no more injury to the property than is absolutely necessary for effecting his purpose. If a new house or a wall be erected so near to an old house as to obstruct its ancient lights, this is a private nuisance, which it is competent to the person injured peaceably to abate: or, if a gate or other obstruction be erected or placed across a public road, this, which is a public nuisance, any of the king's subjects passing that way may beat down and remove.

The second signification of abatement is that of abating a civil action, or an indictment. Here it is taken figuratively, and signifies the beating down or overthrowing such action or indictment. This is effected in an action at law, either by showing, by way of plea, that something has occurred by which the proceeding is *ipso facto* determined, or by stating some matter which renders it imperative on the court to quash, or put an end to, the proceedings. Thus, in the first case, it may be alleged that the plaintiff has taken possession of the property which he seeks by his suit to recover from the defendant. In the second case, it may be shewn that the plaintiff in such proceedings is an alien, an outlaw, or an attainted or excommunicated person, and therefore incompetent by the law of England to maintain an action; or that the defendant is privileged from action, or has been misnamed in the suit; or that there are other persons still living who are equally liable with the defendant, and ought, therefore, to be joined with him in the demand; or that the plaintiff is disqualified from suing by some personal disability, or that the plaintiff or defendant is misnamed. In the former of these cases, the plea informs the court that the action is no longer pending—is already of itself abated by one of the parties, without the interposition of the court: in the latter it calls upon the court to pronounce a judgment which shall put a stop to the present proceedings, without deciding anything upon the main question in dispute between the parties. Where the defendant pleads any matter in abatement which lies peculiarly in his own knowledge, such as his own misnomer, or the non-joinder of other parties as defendants, it is, in general, necessary that the plea should be so framed as to give to the plaintiff that information which shall prevent his falling into a similar mistake, when commencing a new action for the same demand. This is technically called giving the plaintiff a better writ. It is an indispensable rule, where the action is only abateable by plea, that he who takes advantage of a flaw must, at the same time, show how it can be amended. This is, of course, not required where the action is actually abated, and where the plea, though in form a plea in abatement, is substantially a plea in bar, and shows, not that the particular proceeding is misconceived, but that the plaintiff has no *right* to recover by his action the thing which he has claimed.

In the early history of our law, as recorded in the Year Books, the most numerous subjects of discussion are questions arising upon pleas in abatement; and many important legal points were settled in considering whether a writ had or had not abated in fact, or was or was not abateable. Of late years a variety of causes, which cannot be explained without involving the consideration of matters scarcely intelligible to any but a professional reader, have conspired to render pleas in abatement in civil actions of much less frequent use than they formerly were.

The subjects of pleas in abatement, in criminal proceedings, are far more confined than in civil actions. In general, if an indictment assign to the defendant no Christian name or a wrong one, no surname or a wrong one, or no addition, or description of his calling and place of abode, or a wrong one, he may plead this matter in abatement. In modern times, however, misnomer is the only case in which a plea in abatement to an indictment has been at all usual in practice; and, at the present day, such a plea would be of no avail to a defendant,—a statute (7 Geo. IV. c. 64, s. 10) having been lately passed which gives authority to criminal courts of justice to amend the indictment according to the truth upon such a plea being made, and then to call upon the party to plead to the substance of the charge.

The learning upon pleas in abatement, as distributed through the Year Books, is well analysed by Thelwall in his *Digest*; and a full analysis of the law of abatement, in its more modern form, will be found in Comyn's *Digest*—title Abatement. [See also Bacon's *Abridgment*—Blackstone's *Commentaries*, vol. iii. p. 301; vol. iv. p. 334—Stephen on *Pleading*—Jacob's *Law Dictionary*.]

The last species of abatement is that of an abatement into a freehold, wherein, as in the last case, the term abatement is used in a figurative sense. Where, upon the death of a person possessed of freehold lands, another who has no title enters upon those lands to the prejudice of the party entitled as heir or devisee, he is said to abate into the freehold of such heir or devisee. In a state of nature, perhaps, upon the death of an individual who had occupied land, the next person entering upon it would have a better title than any other individual; but our law has, for the preservation of the public peace, given to a man possessed of land the power of nominating a successor as devisee; and in case of his not doing so, has pointed out the person who shall take as heir; and the entering of a person not entitled by either of the methods allowed by law is termed an abatement into the freehold; and this act of intrusion, or interposition between the former possessor and his heir or devisee, is justly considered one of the highest offences which can be committed against the right of freehold property. [Blackstone's *Commentaries*, vol. iii. pp. 167-8.]

ABATIS, a military term, signifying a work composed of felled trees, with the softer branches cut off, laid side by side with the end from which the branches grow towards the enemy; thus forming an obstruction to his progress, and a breast-work for musketry to fire over. This species of defence is often used in fieldworks, where wood, not of too great size, is plentiful. Lines, flanked by bastions, are thus formed, either simply by laying down and fastening the trees, or, if when so placed they would be too high to fire over, by sinking them in a ditch whose section is an angle, with its longest slope towards the enemy. They are sometimes formed against the counterscarp of a rampart, sometimes in the covered way, and may generally be used wherever an obstruction is to be raised to the enemy's progress, provided they can be flanked by a fire sufficient to prevent his destroying them at his leisure.

ABATTOIR, the name given by the French to the public slaughter-houses, which were established in Paris, by a decree of Napoleon, in 1810, and finished in 1818. Paris, previous to the arrangement thus made for the public health and comfort, was, as London now is, subject to the nuisance of having cattle driven through a crowded city, to be slaughtered in yards and hovels of the closest streets. But that capital was not still further exposed, as our metropolis is, to the frightful annoyance of a great cattle-market, held in the very heart of the city: the cattle were bought and sold at the adjacent villages of Scéaux and Passy. Assuredly, the beast-market of Smithfield, and the slaughter-houses of Warwick-lane, and of many other thoroughfares, are evils which ought not to exist in a period of high civilization. The abattoirs of Paris are five in number; three being on the right bank of the Seine, and two on the left. These buildings, which are of very large dimensions, consist of slaughter-rooms, built of stone, with every arrangement for cleanliness, and with ample mechanical aids; and of ox and sheep pens. Each butcher has stalls set apart for his beasts, and conveniences for securing his own forage. A fixed price is paid for the accommodation of the building, and for the labour of the persons engaged in the usual duties of the establishment. In 1824, these payments from the butchers of Paris amounted to a million of francs—about 40,000*l*. When it is considered that about two million head of sheep, oxen, calves, and hogs, are annually slaughtered in London, it is evident that the most serious inconveniences must result from the continuance of the system in which we have so long persevered; and that the establishment of beast-markets, and public slaughter-houses, in suburbs where the population is least dense, would be a measure of great utility. [See *Dulaure, Histoire de Paris*, tom. ix.]

ABAUZIT FIRMIN, born 1679, died 1767, aged 87. His family was descended from an Arabian physician who settled at Toulouse in the ninth century. He was born at Uzès in Languedoc, of Protestant parents in good circumstances, and lost his father when he was only two years of age. In 1685, after the revocation of the Edict of Nantz, he and his brother were seized by the authorities for the purpose of being educated in the Catholic faith. After some time, however, his mother was enabled to effect his escape, and send him to Geneva. For this she was imprisoned, until she also contrived to escape and follow her son. Abauzit applied himself closely to study, and attended to almost every branch of human knowledge. In 1698 he visited Germany, Holland, France, and England, and gained the esteem of many eminent men, among others of Bayle and

Newton. King William wished to retain him in England, but he decided to return to Geneva. There he took part in the translation of the New Testament, which appeared in 1726, and received the thanks of the clergy for his exertions. The Academy offered him a professor's chair in 1723, which he declined, preferring the situation of a supernumerary librarian, without salary. In 1727 the government of Geneva bestowed on him the rights of citizenship. He is one of the most remarkable instances on record of a combination of universality and depth of learning. Every man who talked with Abauzit on his own particular study, imagined that, whatever his general learning might be, his special attention had been reserved for that which they were discussing. Newton addressed himself to Abauzit as a proper person to decide between him and Leibnitz. Pococke, the Oriental traveller, thought he had passed his life in the east. Rousseau imagined that he had devoted himself to the study of ancient music. The latter speaks of him in terms of the highest admiration in his *Héloïse*, being the only instance in which he has thus distinguished a contemporary. In his temper he was so mild and enduring, that an anecdote which is preserved of him shows that those virtues had reached an excess which almost entitles them to the appellation of a disease of the mind. His friends bribed or encouraged his servant to try what lengths he might go with his master. The man, accordingly, neglected to make his bed, of which Abauzit reminded him without reproof. The same neglect, however, was allowed to occur several days running; on which Abauzit called the servant, and said, 'You appear not to like to make my bed; perhaps you think it too much trouble; it is, however, no great matter, as I begin to accustom myself to it.' For a man of his attainments we have not much remaining of Abauzit. With the exception of some antiquarian papers, in Spon's *Histoire de la Ville de Genève* and the *Journal Helvétique*, he printed nothing himself. Some theological works were published after his death, but the greater part of his manuscripts were burnt by his heirs, whose religious opinions differed from his own, which were Unitarian.—[Mostly abridged from the *Biographie Universelle*.]

ABBAS the Great, or, with his full name, Shah Abbas Bahadur Khan, was the fifth king of the Sufi dynasty which ascended the throne of Persia in the year 1501 of our era. During the latter part of the reign of Shah Mohammed Khodabende, his father, he filled the situation of governor in the province of Khorasan; and on the death of that prince in 1586, succeeded him in the government. Khorasan had just then been occupied by the Usbeks, and it was the first object of Shah Abbas to recover possession of it. But his efforts proved for a time ineffectual. Not being able to take Herat, the capital of Khorasan, from the Usbeks, he was obliged to content himself with leaving a garrison at Meshhed, and even this town, considered as sacred by the Shiites on account of the tomb of a celebrated Mohammedan saint, Imam Ali Reza, fell again into the hands of the enemy. About the same time the internal peace of Persia was interrupted by a revolt at Istakhar, which was, however, soon repressed, and terminated with the execution of the prime mover, Yakub Khan. The year 1590 was distinguished by victories in Gilan and Azerbijan over the Turks, who had collected a considerable force on the banks of the river Kur, and threatened Persia with an invasion. The Turks lost, through this campaign, their influence in Gilan, but retained for the present possession of the fortresses of Nuhavend, Tebriz, Tiflis, and almost the whole of Azerbijan and Georgia. During this time, one of the generals of Abbas conquered the province of Lar in the south, and the Bahrein islands in the Persian gulf, important on account of their pearl-fishery.

The Usbeks still remained masters of Khorasan, and, owing to their desultory mode of carrying on their attacks, many attempts at bringing them to a regular action had failed. At last, however, in the year 1597, they were totally defeated by the Persian troops, near Herat, and Khorasan was for a long time released from their predatory incursions.

Two English knights, Sir Anthony, and his brother Sir Robert Sherley, arrived about this time as private travellers in Persia. They were honourably received by Shah Abbas, whose confidence they soon gained to such a degree, that while Sir Robert Sherley remained in Persia, his brother Sir Anthony was sent as envoy from the Persian court to the Christian princes of Europe, to offer them the Shah's friendship, chiefly with a view to some future common undertaking against the Turks, who were then the terror of Europe.

Between Persia and Turkey hostilities were still carried on. Nuhavend, Tebriz, and Bagdad were taken; a Turkish army of 100,000 men was defeated by about half that number of Persians; Abbas recovered Azerbijan, Shirwan, part of Georgia, and Armenia, and subsequently also Kurdistan, Mosul, and Diarbekir; and the Turks were ever after this victory kept in check. They formed a league with the Tartars of Kaptchak, but the united forces of both were vanquished in a battle fought between Sultanieh and Tebriz, A. D. 1618, the last memorable battle that occurred during the reign of Shah Abbas. Negotiations were then commenced between Abbas and the Sultan at Constantinople; but insurrections and conflicts in the frontier provinces, fomented and secretly instigated by the Turkish government, still continued for some time.

Shah Abbas encouraged the trade of Europeans with Persia: he protected the factories which the English, the French and the Dutch had at Gombroon; but he looked with jealousy on the flourishing establishment of the Portuguese on the small island of Ormuz, situated near the entrance of the Persian Gulf, which had been in their possession ever since 1507, when Albuquerque occupied it, and had now become the emporium of an extensive commerce with India, Persia, Arabia, and Turkey. This settlement the Persians and the English East India Company agreed to attack with joint forces. The English furnished the naval, the Persians the military, forces; and the island was taken on the 22nd April, 1622. For this service the English received part of the plunder, and a grant of half the customs at the port of Gombroon; but their hopes of further advantages for their commerce in these parts were frustrated, and the mission of Sir Dodmore Cotton from England to the Persian court, in 1627, likewise failed in procuring them.

After a reign of upwards of forty years, Shah Abbas died at Kaswin, A. D. 1628. Like most of the monarchs of the Sufi dynasty, he was excessively cruel, and hasty in awarding capital punishment often on very slight grounds. All his sons fell victims to his suspicion and jealousy; only one grandson survived him, who succeeded him on the throne as Shah Sufi. Abbas was a zealous Shiite, and used to make frequent pilgrimages to the tomb of Imam Ali Reza, at Meshhed; but he showed great tolerance to those that professed other religions, and especially to Christians. His belief in astrology was so firm that he once even vacated the throne for a short period during which it had been predicted that danger menaced the life of the Shah. He made Isfahan the capital of the empire, and embellished that town by magnificent gardens and palaces. He favoured commerce, and rendered the communications in the interior easier by caravanserais and highways. As a means of securing the authority of the crown, he countenanced the conflict of political parties in the interior; with the same view he formed a new clan of his own, consisting of persons from all classes, and denominated the 'King's friends,' whom he distinguished and attached to his person by many particular favours.

ABBASIDES. The name of this family of sovereigns is derived from their ancestor, Abbas ben Abd-al-Motalleb, a paternal uncle of the Arabian prophet Mohammed. On account of their descent from so near a relation of the prophet, the Abbasides had, ever since the introduction of the Islam, been held in very high esteem among the Arabs, and had at an early period begun to excite the jealousy of the Ommaïade caliphs, who, after the defeat of Ali ben Ali Taleb, the son-in-law of Mohammed (A. D. 661), occupied the throne of the Arabian empire. The Abbasides had already for some time asserted their claims to the caliphat, in preference to the reigning family, when, in A.D. 746, they formed a strong party, and commenced open hostilities against the government of the Ommaïades in the province of Khorasan. Three years afterwards (A.D. 749) the Abbaside Abul-Abbas Abdallah ben Mohammed, surnamed Al-Saffah, or 'the bloodshedder,' was recognized as caliph at Kufa. A battle on the banks of the river Zab, not far from Mosul (in the same neighbourhood where, more than a thousand years before, the battle of Gaugamela had made Alexander master of the Persian empire), decided (Jan. 750 A. D.) the ruin of the Ommaïades. Merwan II., the last caliph of that lineage, fled before the advancing forces of Al-Saffah from Mosul to Emesa, thence to Damascus, and finally to Egypt, where he was overtaken and killed. So great was the hatred of the victorious party against the vanquished royal family, that not less than ninety Ommaïades were doomed to a cruel and ignominious death, while even the remains of those that were already dead, were taken out of their tombs, and publicly insulted. A survivor of the fallen dynasty, Abd-alrahman, a grandson of the caliph Hesham, escaped to Spain, the westernmost province of the Arabian empire. There his name procured him a favourable reception; he was saluted as king, and an Ommaïade lineage continued to reign for nearly three centuries (A.D. 756—1031) over the eight Mohammedan provinces of Spain.

Al-Saffah died in A.D. 753, and was succeeded in the caliphat by his brother Al-Mansur (A.D. 753—774), who removed the seat of government from Damascus to the new-built city of Bagdad. He was successful in wars with the Turcomans and with the Grecian empire in Asia Minor: but the internal tranquillity of his reign was often disturbed by insurrections in the distant provinces. In the reign of his son, Mohdi (A.D. 774—784), a Mohammedan army, under the command of the youthful Harun al Rashid, penetrated the Grecian provinces of Lesser Asia as far as the Hellespont. During the short reign of Mohdi's son, Hadi (784—786), an attempt at an overthrow of the Abbaside dominion was made at Medina, by Hossein, a descendant of Ali ben Abi Taleb.

Hadi was followed by the celebrated Harun al Rashid, a grandson of Al-Mansur, whose early military exploits have already been alluded to. When called to the throne, he soon displayed a love of justice and peace, and a zeal for literature and the arts, which corresponded to his valour as a military commander. He opened friendly communications with Charlemagne: the presents which he sent him (among others a curious sort of clock, a description of which is given by Eginhard), while they show the regard which he entertained for his great European contemporary, afford at the same time an illustration of the progress which the mechanical arts must at that time have made among the Arabs. In conducting the internal affairs of his empire, Harun was chiefly guided by his two ministers, Yahya and Jafar, of the ancient Persian family of the Barmekides, whose ancestors had, through many generations, previous to the introduction of the Islam, held the hereditary office of priests at the fire-temple of Balkh. But the high degree of popularity which the Barmekides enjoyed, aroused Harun's jealousy, and the rashness and cruelty with which he indulged himself in his suspicion by putting to death not only the two ministers, but almost all their relations, form an odious exception to the praise of mildness and equity with which his memory is honoured by Eastern chroniclers. The epoch of his reign has, in the remembrance of Mohammedan nations, become the golden age of their dominion. The wealth and the adopted luxury of the conquered nations had given to social life that refinement, and to the court of Bagdad that splendour, of which so lively pictures are exhibited in many of the tales of the *Arabian Nights*. Flourishing towns sprung up in every part of the empire. Traffic by land and by sea increased with the luxury of the wealthy classes; and Bagdad rivalled even Constantinople in magnificence.

To wage war against the Infidels was, with the Arabs, a matter of religion and of faith: as soon, therefore, as a conquered nation embraced the Mohammedan belief, it was no longer regarded as subject to the victors, but was raised to an equality with them, and formed an integral part of the same body. The different elements of the empire were thus held together by the tie of a common religion, and the language of the Koran (which the Mohammedans have always deemed it unlawful to profane by translations) became the medium of communication for the nations from the banks of the Indus to those of the Tagus and the Ebro. The supreme pontificate and the secular sovereignty, the two elements whose conflict forms the prominent feature in the history of the Christian world during the middle ages, were in the Mohammedan empire united in the person of the caliph, who, invested with the mantle, signet, and staff of the prophet, and bearing the title of Emir al Mumenin, *i.e.* Commander of the Faithful, wielded the supreme spiritual and temporal rule without any other restriction or control besides the ordinances of the established religion. The only formal recognition of the sovereignty of the caliphs (and, subsequently, of all other independent Mohammedan princes) was the prerogative of having the money of the state stamped with their name, and of having their name also introduced into the public prayers at the mosques. According to the ancient Persian plan, the several provinces of the empire were governed by delegates, with military and administrative powers. But this system soon proved fatal to the caliphat: for the lieutenants in the distant parts of the empire would often revolt, and aspire to independent authority. On an expedition to Khorasan, undertaken against such a disloyal satrap, Harun died at Tus, A.D. 808.

The throne was for some years contested between his two sons, Amin and Mamun: but, in A.D. 813, Mamun came to the sole and undisputed possession of it. His reign (A.D. 813—833) forms an important epoch in the history of science and literature, the cultivation of which was conspicuously patronized by that caliph. The Arabs were avowed borrowers in science: they were chiefly indebted to the Hindus and the Greeks; and even what they received from these nations seems often to have exceeded their comprehension. Their claims to originality of invention, and to the merit of having made real additions to the stock of knowledge, are not great; but they are entitled to *our* gratitude for having kept alive and diffused the light of letters, and for having preserved a sort of scientific tradition from classical antiquity, during an age when science and literature in Europe lay buried under ignorance and barbarism. Mamun founded colleges and libraries in the principal towns of his dominions, such as Bagdad, Bassora, Kufa, and Nishabur. Syrian physicians and Hindu mathematicians and astronomers lived at his court; and works on astronomy, mathematics, metaphysics, natural philosophy, and medicine were translated from the Sanscrit and Greek into Arabic. Mamun took personally a particular interest in astronomy. He built observatories, had accurate instruments constructed, improved by their means the astronomical tables, and caused a degree of the meridian to be measured in the sandy desert between Palmyra and Racca on the Euphrates. At his command, Mohammed ben Musa wrote an elementary treatise on algebra, the earliest systematic work extant on that branch of mathematics, for their knowledge of which, as well as for much of their astronomy, the Arabs seem to be chiefly indebted to the Hindus. The investigation of the structure of their own language, and the systematic development of the Mohammedan theology and jurisprudence, both founded chiefly on the Koran, afforded an opportunity of applying practically the principles of the Aristotelian philosophy.

The period of prosperity which the Arabic empire enjoyed under Harun al Rashid and Mamun was only of short duration. The chivalrous enthusiasm with which Mohammed had inspired his nation became soon extinguished under voluptuousness and love of enjoyment. Many provinces in the west (Spain, Fez, and Tunis) had already shaken off their allegiance to the caliphat, and the attachment of others in the east was likewise doubtful. From the north the empire was threatened by the Turks, some tribes of whom had been compelled to adopt the Mohammedan religion. Turkish youths were soon brought as mercenaries to Bagdad, and Motasem (833—842), the brother and successor of Mamun, formed of them a body-guard, which, under the reign of Vathek (842—846), Motawakkel (846—861), and Montaser (861, 862), became to the caliphat what the prætorian guards had been under the Roman emperors. Mostaïn (862—866) was obliged to concede to them the privilege of electing their own commander, and thus lost much of his authority at home, while the provinces of his empire were infested by invasions from the Greeks. Under his successor Motaz (866—868), a native of Sejestan, Yakub al Laith, surnamed Al-Soffar, *i.e.* the brazier, made himself master of Khorasan, Kerman, Persia proper, and Khuzistan, and united these provinces into an independent kingdom, with Nishabur for its capital, which continued in the possession of his family (the Soffarides) till 917.

The successors of Motaz were Mohtadi (868, 869), Motamed (869 — 892), Motadhed (892 — 902), Moktafi (902 — 907), Moktader (907 — 932), and Kahir (932 — 934). Under the reign of Radhi (934—940) the disorder of the empire had reached such a height, that the caliph, in order to restore public order and tranquillity, was obliged to call Mohammed ben Rayek, the governor of Wasith, to Bagdad, and to confide to him, with the title of Emir al Omara, or commander of the commanders, an almost unlimited authority in the government. From this time the caliphat became a mere nominal dignity; all the efficient power was in the hands of the mighty Emirs al Omara, After the short reign of Mottaki (940—943), Mostakfi (943, 944) came to the caliphat; but he was soon dethroned by Moizzeddaula the Buide (properly Bawaihide), who, in concert with his two brothers, had rendered himself master of a great part of Persia and Irak. Moizzeddaula conferred the caliphat, now limited to the mere pontifical dignity and to the possession of the town of Bagdad, on Mothi Lillah (946—973), and reserved to himself the powerful office of Emir al Omara, which continued hereditary in his family during the caliphat of Tayi lillah (973—991), and Kadir billah (991—1031), till the year 1056, when, in the caliphat of Kaïm biamr illah (1031—1074), Bagdad was occupied by the Seljukes under Togrul Beg, whose family retained the authority of Emir al Omara till 1152, while the nominal sovereignty of the caliphat passed from Kaïm biamr illah successively into the hands of Moktadi (1074—1094), Mostajer (1094—1118), Mostarshed (1118—1134), Rashid (1134, 1135); and Moktafi (1135—1160). The sovereigns of those principalities into which the Arabian empire had now dissolved itself, either still recognized the caliph at Bagdad as Imam or supreme pontiff, and thus showed him a sort of spiritual allegiance, or they were Shiites, *i.e.* partizans of the cause of Ali ben Abi Taleb and his descendants, and as such execrated the dominion of the Abbasides. Of the first kind were the Tulunides and Ikshides in Egypt and Syria, and the Tahirides, Soffarides, Samanides, and Gasnevides in Persia and Khorasan; to the second description belonged the Assassines, and the Fatimides in Africa. Moktafi's son Mostanjed (1160—1170) was succeeded in the caliphat by Mostadhi (1170—1179), and Nasir (1179—1226), during whose reign the Tartars under Jingiskhan invaded Persia. Dahir occupied the caliphat only for a few months. His successor, Mostanser (1226—1242), offered for a time a vigorous resistance to the advance of the Tartar conquest; but his son Mostasem was defeated and killed by the Tartar Hulaku, who took Bagdad, and put an end to the government of the Abbasides.

Ahmed, a son of the caliph Dahir, fled to Egypt, where Sultan Bibars, the Mamluk (A.D. 1260), recognized him as caliph. But he soon met his death at Bagdad in an attempt to establish his right to the throne of his ancestors; and Bibars conferred the title of caliph on another Abbaside, Hakem bi-amillah, whose descendants, under the protection of the Mamluks, retained possession of the almost nominal caliphat in Egypt till 1517, when the Osman Turks conquered Egypt. Sultan Selim took the last Abbaside caliph, Motawakkel, to Constantinople, where he kept him for some time as a prisoner, but afterwards allowed him to return to Egypt, where he lived at Kairo till his death, in 1538.

ABBE' is the French term for Abbot, which will be explained in its place. In France, before the Revolution, Abbé was the denomination of a very numerous body of persons, who had little or no connexion with the church, except the apparent one, which they derived from this title. Many of them had not even received the tonsure, which, is in Roman Catholic countries, the first and indispensable mark of the clerical character. So far back as the end of the seventeenth century, we find Richelet, the lexicographer, complaining that there was scarcely a young man, tolerably well made, and who had acquired the air of an ecclesiastic, who did not, by an insufferable abuse, assume the style of Monsieur l'Abbé. 'People,' he adds, 'even stupidly honour with that respectable name any scholar living, who may have put on the short coat, the small neckband, and the little peruke.' Another author, Mercier, writing a century later, describes the same class of characters. 'They are persons,' he says, 'passing under the denomination of Abbé, without any clerical mark or ornament, in a smart coat with gilt buttons, a small opera hat, displaying a high style of frisure of the hair, and the most effeminate manners.' The coat, usually of brown or blue, with the neckband and wig, formed the well-known distinguishing costume of the Abbé. The band, descending under the chin, was originally the common dress of all classes: ecclesiastical persons only wore it shorter than others, in affectation of humility. As for the peruke, which was also of small dimensions, it is said to have been first worn by the Abbés about the year 1660; the Abbé Lariviere, a worthless character, who afterwards became Bishop of Langres, having set the example. This innovation greatly scandalized the more serious members of the ecclesiastical order; and several works were written in vehement condemnation of the abuse. One of these bears the odd title of *Clericus Deperrucatus*, which may be translated *The Church Unperiwigged.* The abbés occupied a very conspicuous place in French society, and discharged a variety of functions. 'In man houses,' writes Mercier, 'we find an Abbé, on whom is bestowed the appellation of friend, and who is in reality but an honest upper servant, commanding the livery servants: he is the humble attendant on Madame, assisting at her toilet, taking charge of household matters in general, and directing the affairs of Monsieur without.' Many of the abbés, however, followed a more useful and creditable way of life. Some acted as private tutors in families, though these were seldom treated with much respect, and were consequently, in general, persons of very inferior qualifications. Others were professors of the university; and a great many employed themselves as men of letters,—in which capacity their labours have given to the title of Abbé an honourable celebrity, and redeemed it from the universal contempt to which swarms of frivolous and intriguing sycophants would otherwise have reduced it.

ABBE'S COMMENDATAIRES, were such abbés as held abbeys in commendam,—that is, with the right of administering their revenues, or a part of them. There were, before the Revolution, between 200 and 300 abbeys in France, which the king had the privilege of conferring in commendam; and it was the expectation of obtaining one of these benefices which induced so many persons to take the title of Abbé. Before obtaining such preferment they used to be called *Abbés de sainte esperance*, abbés of holy hope. After they were thus provided for, they were Abbés Commendataires. The papal bull, which ratified their appointment, commanded them in all cases to get themselves ordained priests within the year, or as soon as they should arrive at the canonical age (five-and-twenty), on pain of the benefice being declared vacant; but it was common to obtain dispensations for disregarding this condition, and most of them remained Secular Abbés, as they were designated; that is, not subjected to any monastic rule. The Abbé Commendataire received the third part of the revenues of his abbey, and also enjoyed certain dignities and privileges which it is unnecessary to specify; but the actual government of the house was committed to the hands of a resident superior, the *prieur claustral*, who was in almost all respects quite independent of the sinecurist, his colleague.

ABBESS, the superior of a nunnery, or other female religious community. An abbess, in the Roman Catholic Church, possesses, in general, the same dignity and authority as an abbot, except that she cannot exercise the spiritual functions appertaining to the priesthood. An abbess, for example,

Costume of an English Abbess
(From Strutt's Ecclesiastical Antiquities).

cannot confess her nuns; although it appears that in ancient times she was allowed to do so; and that the practice was suppressed, according to the learned father Dom Martene, in his treatise on the *Rites of the Church*, in consequence of its having been found that there was no end to the questions which female curiosity would ask. According to a decree of the Council of Trent, an abbess, at the time of her election, ought to be at least forty years old, and to have made profession for eight years; and it is forbidden that any person be elected to the dignity who has not been professed for five years, or is under thirty years of age.

ABBEVILLE, a town in France, in the department of the Somme, and upon the river which gives name to the department. It is situated in a pleasant and fertile valley, and is a place of considerable trade. Its manufactures are various, and include woollen stuffs, such as serges, barracans, &c.; also bed-ticking and linings; rope and twine; and soap. There is also a woollen-cloth manufactory, the most extensive in France, established in 1665, by Van Robais, a Dutchman, who was patronized by the minister Colbert. The cloths are little inferior to those of our own country. Dyeing and bleaching are also carried on. The articles thus made, together with the produce of the neighbourhood, grain, flax, hemp, and oil, constitute the chief exports of the place, which trades with Brittany and with Bayonne. The river at high water enables boats and vessels of one hundred tons to work up to the town. The population of Abbeville is about 19,000; but other accounts make it amount to 30,000, or even 36,000, including the suburbs. It is fortified, but is not to be regarded as in the first class of strong places. The houses are generally well-built, and of brick. A few are of stone, and some few ancient ones of wood. There were, before the revolution, many ecclesiastical establishments, including a collegiate church, and thirteen, if not fourteen, parish churches. Abbeville is twenty-five miles north-west of Amiens, the departmental capital, and ninety-one north by west of Paris. Lat. 50° 7′ north, and long. 1° 49′ east of Greenwich.

ABBEY, a religious community presided over by an abbot or abbess. When the superior was denominated a Prior, the establishment was called a priory; but there was latterly no real distinction between a priory and an abbey. The priories appear to have been all originally off-shoots from certain abbeys, to which they continued for some time to be regarded as subordinate. The wealthiest abbeys, in former times, were in Germany; and of all such foundations in the world, the most splendid and powerful was that of Fulda, or Fulden, situated near the town of the same name in Franconia. This monastery, which belonged to the order of St. Benedict, was founded by St. Boniface, in the year 784. Every candidate for admission into the princely brotherhood was required to prove his nobility. The monks themselves elected their abbot from their own number; and that dignitary became, by right of his office, Arch-Chancellor to the Empress, and Prince-Bishop of the diocese of Fulda. He claimed precedence over all the other abbots both of Germany and of France. One of the first effects of the Reformation, both in England and in Germany, was the destruction of the religious houses; although, even in the Protestant parts of the latter country, a few male and female monastic communities still subsist. In England their extinction was sweeping and complete. The preface to Bishop Tanner's *Notitia Monastica* may be consulted for the most accurate and comprehensive account that has been given of the number and revenues of the English monasteries at the time of the dissolution. From this statement, it appears that, by the Act of Parliament passed in 1535 for the suppression of all the establishments of this kind having a less revenue than 200*l*. a-year, about 380 houses were dissolved; from whose possessions the crown derived a revenue of 32,000*l*., besides plate and jewels to the value of about 100,000*l*. By a subsequent act passed in 1539, all the remaining monasteries were suppressed, to the number of 186; the revenues of these amounted to 100,000*l*. per annum. Besides the monasteries, forty-eight houses of the knight's hospitallers of St. John were also confiscated to the crown. Other authorities make the wealth of the monastic establishments much greater than it would appear to have been from this account; and it is probable that the revenues of many of them, at the period of the dissolution, had been considerably diminished by the precautions which the abbots were led to take in anticipation of that event. Camden states the whole number of the religious houses that were suppressed at 645. In the early times of the French monarchy, the term abbey was applied to a duchy or earldom, as well as to a religious establishment; and the dukes and counts called themselves abbots, although remaining, in all respects, secular persons. They took this title in consequence of the possessions of certain abbeys having been conferred upon them by the crown.

ABBOT, the title of the superior of certain establishments of religious persons of the male sex, thence called Abbeys. The word *Abbot*, or *Abbat*, as it has been sometimes written, comes from *Abbatis*, the genitive of *Abbas*, which is the Greek and Latin form of the Syriac *Abba*, of which the original is the Hebrew *Ab*, father. It is, therefore, merely an epithet of respect and reverence, and appears to have been at first applied to any member of the clerical order, just as the French Père and the English Father, having the same signification, still are in the Catholic Church. In the earliest age of monastic institutions, however, the monks were not even priests; they were merely holy persons who retired from the world to live in common, and the abbot was that one of their number whom they chose to preside over the association. In regard to general ecclesiastical discipline, all these communities were, at this time, subject to the bishop of the diocese, and even to the pastor of the parochial district, within the bounds of which they were established. At length it began to be usual for the Abbot, or, as he was called in the Greek Church, the Archimandrite (that is the Chief Monk), or the Hegumenos (that is the Leader), to be in orders; and since the sixth century monks generally have been priests. In point of dignity an abbot is considered to stand next to a bishop; but there have been many abbots in different countries who have claimed almost an equality in rank with the episcopal order. A minute and learned account of the different descriptions of abbots may be found in Du Cange's Glossary, and in Carpentier's Supplement to that work. In England, according to Coke, there used to be twenty-six abbots (Fuller says twenty-seven), and two priors, who were Lords of Parliament, and sat in the House of Peers. These, sometimes designated Sovereigns, or General Abbots, wore the mitre (though not exactly the same in fashion with that of the bishops), carried the crozier (but in their right hands, while the bishops carried their's in their left), and assumed the episcopal style of Lord. Some croziered abbots, again, were not mitred, and others who were mitred were not croziered. Abbots, who presided over establishments that had sent out several branches, were styled Cardinal-Abbots. There were

Costume of an English Mitred Abbot
(Principally from Dugdale's Monasticon).

likewise, in Germany, Prince-Abbots, as well as Prince-Bishops. In early times we read of Field-Abbots (in Latin, *Abbates Milites*) and Abbot-Counts (*Abba-Comites*, or *Abbi-Comites*). These were secular persons, upon whom the sovereign had bestowed certain abbeys, for which they were obliged to render military service as for common fiefs. A remnant of this practice appears to have subsisted in our own country long after it had been discontinued on the continent. Thus, in Scotland, James Stuart, the natural son of James V., more celebrated as the Regent Murray, was, at the time of the Reformation, Prior of St. Andrew's, although a secular person. And the secularization of some of the German ecclesiastic dignities has since occasioned something like a renewal of the ancient usage. We have in our day seen a prince of the House of Brunswick (the late Duke of York) at the same time Commander-in-Chief of the British army and Bishop of Osnaburg. The efforts of the abbots to throw off the authority of their diocesans long disturbed the church, and called forth severe denunciations from several of the early councils. Some abbeys, however, obtained special charters recognizing their independence; a boon which, although acquired at first with the consent of the bishop, was usually defended against his successors with the most jealous punctiliousness. Many of the abbots lived in the enjoyment of great power and state. In ancient times they possessed nearly absolute authority in their monasteries. 'Before the time of Charlemagne,' says Gibbon, 'the abbots indulged themselves in mutilating their monks, or putting out their eyes; a punishment much less cruel than the tremendous *vade in pace* (the subterraneous dungeon, or sepulchre), which was afterwards invented.' The picture which this writer draws of what he calls 'the abject slavery of the monastic discipline' is very striking. 'The actions of a monk, his words, and even his thoughts, were determined by an inflexible rule, or a capricious superior: the slightest offences were corrected by disgrace or confinement, extraordinary fasts, or bloody flagellation; and disobedience, murmur, or delay, were ranked in the catalogue of the most heinous sins.' The external pomp and splendour with which an abbot was in many cases surrounded, corresponded to the extensive authority which he enjoyed within his abbey, and throughout its domains. St. Bernard is thought to refer to the celebrated Luger, Abbot of St. Denis, in the beginning of the twelfth century, when he speaks, in one of his writings, of having seen an abbot at the head of more than 600 horsemen, who served him as a cortege. 'By the pomp which these dignitaries exhibit,' adds the Saint, 'you would take them, not for superiors of monasteries, but for the lords of castles,—not for the directors of consciences, but for the governors of provinces.' This illustrates a remark which Gibbon makes in one of nis notes:—'I have somewhere heard or read the frank confession of a Benedictine Abbot, "My vow of poverty has given me 100,000 crowns a-year, my vow of obedience has raised me to the rank of a sovereign prince."' Even in the unreformed parts of the continent, however, and long before the French Revolution, the powers of the heads of monasteries, as well as those of other ecclesiastical persons, had been reduced to comparatively narrow limits; and the sovereignty both of abbots and bishops had been subjected in all material points to the authority of the civil magistrate. The former became merely guardians of the rule of their order, and superintendents of the internal discipline which it prescribed. In France this salutary change was greatly facilitated by the concordat made by Francis I. with Pope Leo X., in 1516, which gave to the king the right of nominating the abbots of nearly every monastery in his dominions. The only exceptions were some of the principal and most ancient houses, which retained the privilege of electing their superiors. The title of Abbot has also been borne by the civil authorities in some places, especially among the Genoese, one of whose chief magistrates used to be called the Abbot of the People. Nor must we forget another application of the term which was once famous in our own and other countries. In many of the French towns there used, of old, to be annually elected from among the burgesses, by the magistrates, an Abbé de Liesse (in Latin, Abbas Lætitiæ), that is, an Abbot of Joy, who acted for the year as a sort of master of the revels, presiding over and directing all their public shows. Among the retainers of some great families in England was an officer of a similar description, styled the Abbot of Misrule; and in Scotland the Abbot of Unreason was, before the Reformation, a personage who acted a principal part in the diversions of the populace, and one of those whom the zeal of the reforming divines was most eager in proscribing.

ABBOT, GEORGE, an English prelate of the seventeenth century, more remarkable for the circumstances of his personal history than on any other account. He was born in 1562, at Guilford, in Surrey, where his father was a poor clothworker. Aubrey, the antiquary, in the curious little volume which he published in 1696, under the title of *Miscellanies*, tells a marvellous story of a dream which the mother of George Abbot had, that he would become a great man. In spite of the dream the boy might have remained a clothworker, like his father, had there not been in those days many admirable public institutions for the education of the children of the humbler classes. George Abbot and his elder brother, Robert, were put to the grammar-school of their native town, and in due time proceeded to Baliol College, Oxford. George entered the University in 1578, and in 1597 obtained his first preferment by being elected Master of University College. After this he was also three times appointed Vice-Chancellor of the University. These academic honours seem to show that his reputation and influence at Oxford must have been considerable; but the high standing which he enjoyed has been attributed as much to the zeal with which he opposed Popery and Arminianism as to his superior ability or learning. There had already commenced between him and Laud that violent opposition of theological sentiment, which, involving them eventually in political hostility and in a contest of personal ambition, made them rivals and enemies for life. The Master of University College, however, must have been in considerable esteem for his erudition as well as for his orthodoxy, seeing that we find him in 1604 appointed one of the persons charged with the new translation of the Bible. He was one of eight to whom the whole of the New Testament, with the exception of the Epistles, was entrusted. In 1608 he was appointed chaplain in the establishment of the Earl of Dunbar, at this time the king's chief favourite. This connexion proved of the most important consequence to Abbot's future fortunes. Soon after it was formed, the earl was despatched to Scotland by the king, in order to commence that attempt to bring about a uniformity between the two national churches, their persevering prosecution of which so greatly contributed to the disastrous fate of the line of Stuart. Abbot accompanied him on this mission, and gave himself to its object with so much zeal as to secure the highest approbation and favour both from the earl and the monarch. His course of professional promotion, hitherto so slow, now proceeded with almost unexampled rapidity. He had in 1609 obtained the Deanery of Gloucester, and in December of that same year he was made Bishop of Lichfield and Coventry. In the February following he was transferred to the See of London; and, finally, in little more than a month afterwards, elevated to the Archbishopric of Canterbury. It is probable that Abbot was indebted for his elevation principally to his being the object at the moment of that capricious favoritism for which James was so remarkable throughout his reign. Abbot at this time did not disdain to court his royal master with the most profuse expenditure of that flattery which he loved so well to receive from others, and not unfrequently used to bestow on himself. Both Fuller and Clarendon have expressed a belief that, had the system of severity begun by Archbishops Whitgift and Bancroft not been interrupted by the intervention of the opposite politics of Abbot, Calvinism and dissent would have been extirpated from England, and the political convulsions which arose in the next reign, from the effervescence of these elements, would have been prevented. We do not think that this result would have followed; but, if it had, it is quite certain that the utter extinction of English liberty would have been its accompaniment. Abbot, however, although his theology was of a different complexion from that of his predecessor Bancroft, soon showed himself scarcely less inclined to stretch to their utmost extent all the powers and prerogatives of his office. In the Court of High Commission his conduct was as arbitrary and oppressive towards certain descriptions of delinquents as that of any one who had ever presided over that ecclesiastical tribunal; and he manifested the most marked disposition to set up its authority as superior to that of both the statute and the common law. It is also an accusation brought against him that, never having held a parochial charge himself, he was apt to be inattentive and overbearing towards the inferior or working clergy. In other respects, Archbishop Abbot, though a stern and rigid ruler of the establishment, was active and zealous in the performance of all the duties of his high station. After having reached the summit of professional advancement, he seems, like some other ambitious characters, Coke, for example, and Shaftesbury, to have exchanged the servility by which he rose for an opposite demeanour, and from the supple and cringing courtier to have sprung up into the bold advocate of popular rights and popular politics. Before obtaining the archiepiscopal dignity, Abbot had professed the doctrines of divine right and passive obedience in their most comprehensive and slavish form. Now, however, when circumstances placed him in opposition to the rising influence of his old adversary, Laud, he soon came to adopt and act upon principles in politics, as well as in religion, removed as far as possible from those of that headlong zealot of arbitrary power.

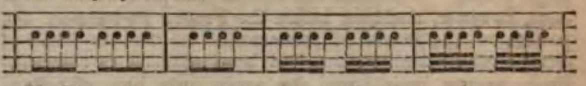
The bright fortunes of Abbot were, however, clouded by an occurrence of which his enemies took signal advantage. On the 24th of July, 1622, the Archbishop (prelates then did not think it unbecoming their office to engage in secular sports) was occupied in a stag hunt in Lord Zouch's park at Harringworth, in Hampshire, where he was so unfortunate as to discharge, while he sat on horseback, a barbed arrow from his cross-bow, which struck one of the park-keepers, Peter Hawkins, in the fleshy part of the left arm, and occasioned the man's death in less than an hour. The party in the church and state to whom Abbot was opposed, employed every effort to turn this accident to his disadvantage, both with the public and with the king; and although James very sensibly remarked that 'an angel might have miscarried in this sort,' he found it necessary to yield so far to the clamour that was raised, as to appoint a commission to consider the case of the archbishop, and to determine whether he had not, by this act of chance-medley, incapacited himself, as Laud and his partizans asserted, for discharging the duties of his office. The adjudication of the commissioners was, that nothing more than an irregularity had been committed, but that it would be necessary for the archbishop to receive the king's pardon, and also a dispensation, before he could resume the exercise of his functions. These forms were accordingly gone through; but the affair, although thus far satisfactorily terminated, gave great vexation and distress to Abbot, both from the scandal to which it subjected him, and from the feelings with which he naturally and unavoidably contemplated the lamentable event of which he had been, though unintentionally, the cause. It is said that, throughout the remainder of his life, he observed a monthly fast on the day of the week which had thus stained his hand with blood; and he also settled a pension of twenty pounds for life on Hawkins's widow. After this he withdrew for some time from his attendance at the Council Board, and took no part in public affairs. The following year, however, on hearing it reported that the king intended to proclaim a toleration to the Papists, he wrote a letter to his Majesty, dissuading him from that measure. He also, soon after this, strenuously opposed in Parliament the projected match between the Prince of Wales and the Infanta of Spain. On the 2nd of February, 1626, Abbot crowned Charles I. in Westminster Abbey, Laud officiating as Dean of Westminster. The new reign confirmed the ascendancy of this latter personage and his confederate Buckingham, and left the Archbishop and his politics less influence at Court than ever. In these circumstances he selected and steadily persevered in that independent path in which alone he was now to find either honour or safety. In 1627, when Dr. Manwaring was brought to the bar of the House of Lords, and sentenced to be fined, admonished, suspended, and imprisoned, for a sermon in which he asserted that 'the king is not bound to observe the laws of the realm concerning the subjects' rights and liberties, but that his royal will and command in imposing loans and taxes, without common consent in Parliament, doth oblige the subjects' conscience upon pain of eternal damnation,' Abbot, in reprimanding the culprit, by order of the House, expressed in energetic terms his abhorrence of so audacious a doctrine. He also refused to license another discourse of a similar description, which had been preached at Northampton by Dr. Sibthorp, and for this he was suspended from his archiepiscopal functions, and ordered into confinement in one of his country houses. This most arbitrary and oppressive treatment was *mainly* the work of his vindictive enemy Laud, whose character, accordingly, the archbishop has delineated with a pen dipped in gall, in a narrative of the affair which he drew up in his own vindication, and which Rushworth has printed. It was found necessary, however, soon after, to restore him to favour, and he received his summons as usual to the Parliament which assembled in March, 1628. During the rest of his life he continued the same course of opposition to the arbitrary and oppressive measures of the Court; and by the resistance which he offered, as far as lay in his power, to the insane counsels of Laud, may be said to have established a claim to be regarded as a patriot in the termination of his career. He died at his palace of Croydon on Sunday, the 4th of August, 1633, and was buried in the church of his native town of Guilford, where a sumptuous monument is erected to his memory. He was the founder of a well-endowed hospital, which still exists in that town; and other instances are recorded of his charity and munificence. He was succeeded in the primacy by Laud, who soon brought matters to such a pass as overthrew both himself and the church.

Archbishop Abbot is the author of several literary productions, among which is *A Brief Description of the whole World*, published in 1636. His brother Robert was raised to the see of Salisbury in 1615, but died on the 2nd of March, 1618. The archbishop's youngest brother, Maurice Abbot, was an eminent London merchant, and was, in the course of his life, one of the first Directors of the East India Company, Lord Mayor, and representative of the City in Parliament. He died in 1640. The sons of the poor cloth-worker were thus singularly lucky in their worldly advancement.—[See *Biographia Britannica*—*Wood's Athenæ Oxonienses*, by Bliss—*Fuller's English Worthies*—*Bayle's Dictionnaire Critique*—*Rushworth's Collection*—*Southey's Book of the Church*.]

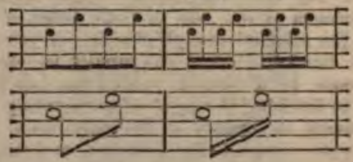
ABBREVIATION, a mathematical term, given to the process by which a fraction is reduced to lower terms. Thus the division of the numerator and denominator of $\frac{16}{24}$ by 8, which reduces it to $\frac{2}{3}$, *abbreviates* the fraction.

ABBREVIATION (*in Music*) is a kind of stenography, or short-hand, which much diminishes the labour of the composer and copyist, and ought to be well understood by every performer. It not only frequently happens that the same note is reiterated, but the same passage is repeated, and the necessity of writing at length such repetitions is avoided by the use of certain well-contrived, simple abbrevitions. Those most commonly employed are:—I. One dash, or more, through the stem of a minim or crotchet, or under a semibreve, by which such note is converted into as many quavers, semiquavers, &c., as it is equal to in time. Ex.

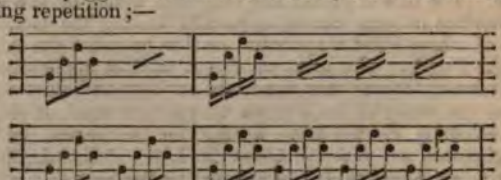
are to be played thus,—



II. Two alternate notes frequently repeated, are commonly abridged in the following manner,—



III. Arpeggios are thus contracted, the dash alone denoting repetition;—



IV. The word *simili* (*the same*) signifies that the group of notes is to be repeated. *Bis* (*twice*) written over a bar, or a passage, denotes repetition. The abbreviations of Italian or other terms used in music, will be found under the respective words.

ABBREVIATIONS, the shortening of a word or phrase, made either by omitting some letters or words, or by substituting some arbitrary mark.

Abbreviations are of two kinds; first, those which are used in familiar speech, by which two words are made one, as can't for can not, won't for will not, &c., and those which are employed in writing only; our business is with the latter.

Before the invention of printing, every expedient to abridge the enormous labour of copying would be naturally adopted, and the principle, once introduced, was followed where the necessity which led to its first employment no longer existed. Latin inscriptions are not unfrequently quite unintelligible to the best scholar who has not given the subject his particular attention, and many are ambiguous even to the most skilful. The most usual Latin abbreviation is the initial letter instead of the whole word; whether a name, as M. for Marcus, P. for Publius; or a relation, as F. for filius, a son; or an officer, as C. for consul, Qu. for quæstor, &c.

The Rabbins carried this practice to a great extent; and although, in copying the Bible, they carefully abstained from abbreviations, their other writings are filled with them. They even carried their abbreviations into their common tongue, and when they had contracted a name or sentence, by taking the initials only, they made words of the unconnected letters by the interposition of vowels. Thus, for Rabbi Levi ben Gerson, they took the first letters, R.L.B.G.; and, by the interposition of vowels, made the word Ralbag.

In the middle ages the practice of abbreviating increased; and even in printing, where the employment of contractions was much less necessary, the old mode was by no means abandoned. Many writings became unintelligible; and in matters of law and government the difficulties thus created demanded the interposition of Government. An Act of Parliament was passed in the fourth year of George II., by which the use of abbreviations was altogether forbidden in legal documents; and although this was so far modified by another Act, within a year or two, allowing the use of those of common occurrence, the old practice was never completely revived. A few only are still employed, chiefly in titles, coins, and commercial transactions; the most important of which follow,—

ABDALLATIF, or, with his full name, MOWAFFIKEDDIN ABU MOHAMMED ALLATIF BEN YUSSUF BEN MOHAMMED BEN ALI BEN ABI SAID, a distinguished Arabic writer, whose name has become familiar to us chiefly through an excellent description of Egypt, of which he is the author. The Baron Silvestre de Sacy has appended to his French translation of this treatise a notice of the life of Abdallatif, taken from the bibliographical work of Ebn Abi Osaibia, who knew Abdallatif personally, and to a great extent quotes an account of his life written by himself.

We learn from this notice that Abdallatif was born at Bagdad in A.H. 557 (A.D. 1161). From his earliest years he received a lettered education. Agreeably to the prevailing fashion of his age and country, which considered a thorough familiarity with the copious and classical Arabic language as the indispensable groundwork for every liberal acquirement, he was led to commit to memory the Koran, the much-admired Makamat, or novels of Hariri, and other compositions distinguished for the purity and elegance of their diction, besides several works professedly treating on style or grammar. Next to these philological studies, he had already bestowed some attention on Mussulman jurisprudence, when the arrival at Bagdad of Ebn al Tateli, a naturalist from the western provinces of the Arabian empire, attracted his curiosity towards natural philosophy and alchemy, of the illusory nature of which latter pursuit he seems not till late, and after much waste of time and labour, to have convinced himself.

Damascus, the residence of Saladin, had about this time, through the liberality of that celebrated sultan, become a rallying point for learned men from all parts of the Mohammedan dominions. It is here that we and Abdallatif commencing his literary career by the publication of several works, mostly on Arabic philology. But the celebrity of several scholars then residing in Egypt, among others the Rabbi Moses Maimonides, drew him to that country to seek their personal acquaintance. A letter from Fadhel, the vizir of Saladin, introduced him at Kairo, and he was delivering lectures there while Saladin was engaged with the crusaders at Acca (St. Jean d'Acre). Soon, however, the news of Saladin's truce with the Franks (A.D. 1192) induced Abdallatif to return to Syria, and he obtained from Saladin a lucrative appointment at the principal mosque of Damascus. After the death of Saladin, which took place in the next year, we find Abdallatif going back to Kairo, where he lectured on medicine and other sciences, supported for a time by Al-Aziz, the son and successor of Saladin. It was during this residence at Kairo that Abdallatif wrote his work on Egypt. But the troubles of which Egypt now became the scene, induced Abdallatif to retire to Syria, and subsequently to Asia Minor, where he seems to have lived for a long time quietly at the court of a petty prince, Alaeddin Daud, of Arzenjan. After the death of that prince (A.D. 1227) he went to Aleppo, to lecture there partly on Arabic grammar, and partly on medicine and on the traditions, an important branch of Mohammedan theology and jurisprudence. Four years after this, Abdallatif set out on a pilgrimage to Mecca, and took his route through Bagdad, to present some of his works to the then reigning caliph Mostanser, when he died there, A.D. 1231.

Ebn Abi Osaibia has given a list of the works composed by Abdallatif, which, in the Arabic appendix to Baron de Sacy's translation, fills three closely-printed quarto pages. The description of Egypt, through which his name has become so familiar to all friends of antiquarian research in Europe, and in which he displays an accuracy of inquiry, and an unpretending simplicity of description almost approaching to the character of Herodotus, is dedicated to the caliph Nasir ledin-illah. It is divided into two books: the first treats, in six chapters, on Egypt generally, on its plants, its animals, its ancient monuments, peculiarities in the structure of Egyptian boats or vessels, and on the kind of food used by the inhabitants; the second book gives an account of the Nile, the causes of its rise, &c., and concludes with a history of Egypt during the dreadful famines of the years 1200 and 1201.

The only MS. copy of this work, of the existence of which we are aware, is preserved in the Bodleian Library at Oxford. From this MS. the Arabic text was edited for the first time at Tübingen, in 1787, by Paulus, and again, with a Latin translation, by the late Professor White, at Oxford, 1800, 4to. The French translation published by Baron de Sacy, under the title *Relation de l'Egypte*, &c. (Paris, 1810, 4to.)

beside its greater fidelity, has, through the copious notes added to it, become one of the most important works that the scholar can consult on the geography, the history, or the antiquities of Egypt.

ABDERA, a Greek town situated near the mouth of the Nestus (now the *Mesto*, or *Kara-sou*, i.e. *black-water*), in Thrace. It was originally founded by some Greeks of Clazomenæ, but owed its importance to a colony of Ionian Greeks from Teos, who left their native city (B.C. 557) when Cyrus had conquered Crœsus, king of Lydia, and was attacking the cities of Ionia. Xerxes passed through Abdera (B.C. 480) on his unsuccessful expedition against Greece. The people of Abdera had some of the Thracian tribes for their neighbours, who, we may conjecture, often rendered their situation uncomfortable and dangerous by their predatory incursions and insecure alliance. On one occasion they were rescued by Chabrias, the Athenian general, from the attacks of the Triballi.

Under the Romans, Abdera was a free city (Plin. iv. 11), which title marks a place of importance at that period. The epicure may be interested in learning that mullets were plentiful and good at Abdera. Its literary fame rests on the two names of Democritus and Protagoras.

Some geographers place Abdera east of the Nestus, but this is directly contrary to the testimony of Herodotus, who says that the river ran through the town. The exact site of this place is, we believe, unknown.

ABDICATION (from *Abdicatio*), in general is the act of renouncing and giving up an office by the voluntary act of the party who holds it. Though the expressions are frequently confounded, the word abdication differs from resignation in this, that the former signifies a total and unconditional renunciation of an office; whereas by the latter term is meant a relinquishing in favour of another. As to the cases in which an abdication will be presumed, from actions inconsistent with and subversive of the essential nature and object of the office held, see Blackstone's *Commentaries*, vol. i. p. 210-212, and iv. p. 78, where mention is made of the resolution of the legislature, in 1688, that King James II. had, by acts subversive of the constitution of the kingdom, by breaking the original contract between king and people, virtually renounced the authority which he claimed by that very constitution, and that, therefore, the throne had become vacant. It appears, by the parliamentary debates at that period, that in the conference between the two Houses of Parliament, previous to the passing of the statute which settled the crown upon William III., it was disputed whether the word 'abdicated,' or 'deserted,' should be the term used, to denote in the Journals the conduct of James II. in quitting the country. It was then resolved that the word 'abdicate' should be used, as including in it the mal-administration of his government.

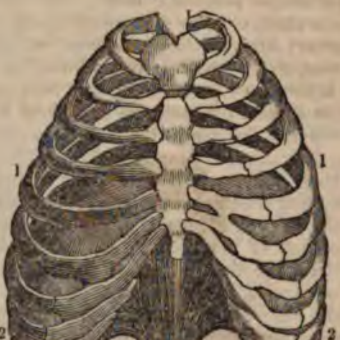
ABDOMEN; the Belly, from *Abdo*, to hide, because it conceals or hides its contents. The last syllable is only a termination. The *lower belly*, Imus Venter, Alvus, Gaster, &c. &c., are synonymous.

The human body is divided by anatomists into three portions, the head, the trunk, and the extremities. The head and trunk enclose cavities which contain the organs or the instruments by which the most important functions of the living body are performed. The trunk forms two cavities, the superior of which is termed the Thorax or Chest, and the lower constitutes the Abdomen.

In the artificial skeleton nothing is shown, because nothing remains, except the mere framework of the body or the bones; but in the natural state, when the soft parts remain as well as the bones, there is a complete partition between the cavity of the chest and that of the abdomen (*fig.* I. 1, 2.) This partition is effected by means of an organ which is termed the Diaphragm (*fig.* I. 1, 2.), a name derived from a Greek word signifying to divide. The Diaphragm is composed partly of membrane, but chiefly of muscle. It is placed transversely across the trunk at about its middle portion, dividing it into two pretty nearly equal halves (*fig.* I. 1, 2.). But the Diaphragm is a moveable body; it is in fact one of the main organs of respiration; its chief function consists in alternately increasing and diminishing the capacity of the thorax and abdomen; for a purpose in the animal economy which will be fully explained hereafter. [See Respiration.] But since the very partition which separates these two cavities from each other is perpetually changing its relative position, now encroaching upon the one, and now upon the other, it is obvious that their actual capacity must be constantly varying.

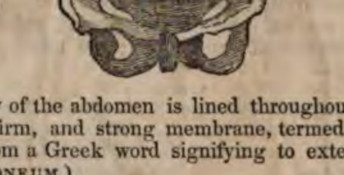
The cavity of the Abdomen is bounded above by the Diaphragm (*fig.* I. 3.), below by the bones of the Pelvis or Basin (*fig.* I. 3, 3, 3, 3.), which may be considered as belonging to the bones of the lower extremities, before and at the sides by the abdominal muscles, behind partly by the muscles of the loins, and partly by the bone of the spine. The spine, as will be shown hereafter, (See Spinal Column,) is composed of a number of separate bones, each of which is termed a vertebra. The vertebræ are firmly united together, and by their union form what is commonly called the back-bone, termed by anatomists the spinal or the vertebral column.

Fig. I.



The cavity of the abdomen is lined throughout by a thin, but dense, firm, and strong membrane, termed the Peritoneum, from a Greek word signifying to extend around. (See Peritoneum.)

Fig. II.



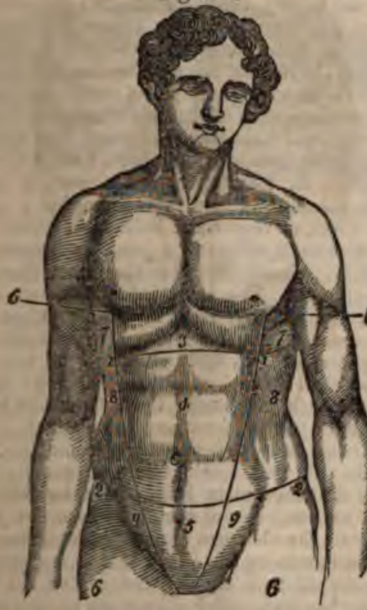
Diaphragm removed from its natural situation between the Chest and Abdomen.

We have spoken of the abdomen as a cavity, but without explanation, this mode of expression may occasion misconception. During the state of life there is no cavity. The abdomen is always completely full. It has been stated that the diaphragm alternately enlarges and diminishes the space proper to the abdomen; but the abdominal and lumbar muscles which form so large a part of the boundaries of the abdomen in front, at the sides and behind, in like manner alternately contract and relax. The consequence is, that a firm and uniform pressure is at all times maintained upon the whole contents of the abdomen, so that there is always the most exact adaptation of the containing to the contained parts, and of the viscera one to the other, not the slightest space or cavity ever intervening either between the walls of the abdomen and its viscera, or between one viscus and another. By the cavity of the abdomen, therefore, is not meant what the expression might at first view seem to denote, namely, a void or empty space; but the term is merely employed to mark the extent of the boundary within which the abdominal viscera are enclosed.

When the number, the diversity, the proximity, the relation, and the importance of the organs contained within the abdomen is considered, it will be obvious that it must be a matter of absolute necessity to the anatomist, the physiologist, the physician, and the surgeon, to mark with accuracy the situation of each. An effectual expedient for the accomplishment of this object is now in universal use. It consists in dividing the whole extent of the abdomen into certain parts or regions. It must be borne in mind that this division is altogether arbitrary, and is adopted not because there is any such division in nature, but solely because it is convenient for the purposes of science. The abdomen, then, is artificially mapped out into the following regions.

Two imaginary lines are drawn across the abdomen, one of which is supposed to extend from about the seventh rib on one side to the same point on the opposite side (*fig.* III. 1. 1.). The second line is supposed to extend from the fore part of the large bone of the pelvis to the same projecting point on the other side (2. 2.). These lines mark out three large and distinct spaces (3, 4, 5.). The space above the upper line is termed the Epigastric Region (3.). The space below the lower line is termed the Hypogastric Region (5.). The space included between the two lines is termed the Umbilical Region (4.).

Fig. III.



Two lines are next supposed to extend vertically, one on each side from between the seventh rib to the prominence formed by the large bone of the pelvis (*fig.* III. 6. 6.). By these vertical lines the three first regions are still further subdivided in the following manner:—The right and left parts of the Epigastric region form two distinct regions (7. 7.); these are termed the right and left Hypochondriac (7. 7.), while the central part retains the name of the Epigastric (3.). In like manner the right and left parts of the umbilical region form two distinct regions (8, 8.), which are termed the Lumbar Regions (8, 8.), while the central part retains the name of the Umbilical (4.). Moreover, the right and left parts of the hypogastric regions are at the same time each divided into two, which are termed the Iliac Regions (9, 9.), while the central part is termed the Region of the Pubis (5.).

This arrangement being once understood, it is easy to speak with precision of the situation of any of the abdominal viscera. He who has made himself thoroughly acquainted with these regions, and with the organs situated in each, can tell what viscera would be wounded supposing a sharp instrument were to pass from the fore to the back part of the body, entering at any given point of the abdomen. He who can tell this has acquired, in a practical point of view, an invaluable piece of information. He who cannot tell this is in danger, in the practice either of medicine or surgery, of committing perpetual and fatal mistakes; and, therefore, until he can tell this, no student of medicine who has a clear conception of the duties of his profession, and who wishes to perform these duties conscientiously, can be at rest.

Knowledge of structure is necessary to the knowledge of function; knowledge of natural function is necessary to the knowledge of diseased function; knowledge of the nature of disease is necessary to the cure of disease. The natural situation and relation of organs, the healthy structure of organs, the sound action of organs, must therefore form the subject of the daily study of the physician and surgeon, since this knowledge is the basis of the science of the one and the art of the other. Now, among the means of acquiring this knowledge, one of the most direct and certain is the examination of the external parts of the body. There are organs, indeed, placed beyond the reach of any external examination. The disordered states of such organs can be ascertained only by symptoms. The diseases of such organs do not alter the external appearance of the body; they afford no outward sign by which the inward state can be distinguished. But whenever the situation of organs is such as to place them within the reach of external examination, this mode of investigating their diseased affections is the simplest, the readiest, and the surest; and there is no part of the human body so well adapted for this kind of examination as the abdomen. Its walls are soft and yielding; some of its most important organs lie immediately beneath the surface; though they cannot be seen they can be felt; and several of their morbid conditions can therefore be ascertained with clearness and certainty.

Not only are some of the diseases of the abdominal viscera visible to the naked eye, but they are even strikingly expressed; for they either cause a permanent change in the configuration of the abdomen, or they produce a temporary alteration of its natural movements, or they occasion both effects. And as the abdomen affords the greatest facility for the external examination of its contents, so the varied and extended functions performed by its organs render this examination of paramount importance. There is no other part of the body in which so many different organs are crowded together; in which they lie so close to one another: in which they are so much intermixed; in which they are so liable, by the operation of internal morbid causes, to be removed from their natural situation; in which the diseases of one influence by sympathy to so great an extent the state of others; in which the symptoms or signs of disease are so numerous, so complex, so deceptive; in which disease is so apt to extinguish or embitter life, and the oversight, or the misconception of which proves so certainly injurious, and so often fatal.

Both in the male and in the female it often happens that diseases not to be ascertained, or at any rate exceedingly apt to be overlooked, or mistaken, if the region of the part affected be covered with its ordinary clothing, become manifest the moment the part in question is uncovered; or if not, are rendered obvious by other modes of inspection to which the removal of the clothing is indispensable. As an example of this, it may be worth while to give some illustration of the extent and value of the information to be derived from an external examination of the abdomen, when carefully and accurately performed, were it only to remove the obstacles sometimes opposed to this examination on the part of the patient from false delicacy, and to exhibit the mischiefs that may result from the neglect of it, on the part of the practitioner, whether from ignorance or from indolence.

The external examination of the Abdomen, or the Exploration of it, as it is technically termed, is comprised in simple inspection, manual examination, and percussion.

1. The simple inspection of the abdomen often affords valuable information. The mere alteration of its form is sometimes of itself sufficient to determine the seat and the nature of the disease. In each case of diseased organs the change is different; in each it is peculiar, and even characteristic. The abdomen may be affected with spasm, as in the disease called colic, or with inflammation, as in the disease called enteritis. Life may depend on the promptitude with which the true nature of the affection is detected. One set of remedies is required for one of these diseases, and a totally different set for the other. Remedies essential to the preservation of life, if the disease be inflammation, may be destructive of life, if the disease be merely spasm; and if, under the notion that the disease is spasm, the remedies proper for inflammation be not employed, death may be the consequence of the error in less than twenty-four, or even

twelve, hours. In both affections the pain may be the same; and several other symptoms may be similar, but the form of the abdomen may be alone sufficient to determine the true nature of the malady; for, if it be inflammation, the abdomen will be rounded, enlarged, and distended; while, if it be spasm, it will be drawn in and contracted. There are affections which place life in the most imminent danger, especially in children, in which it is difficult, if not impossible, to determine, from the symptoms alone, whether the seat of the disease be in the brain, or in the inner coat of the intestines. Suppose it be in the brain; one set of remedies are required, which must be applied to the head. Suppose it be in the intestines, a different sort of remedies is required, which must be applied to the belly. An index is sometimes afforded to the real seat of the disease, by the mere form of the abdomen; while its size, combined with its form, oftener affords a still more certain guide; and so does any deviation from its natural movements.

2. Manual examination affords still more correct and complete information relative to the condition of the abdominal organs. The size, the tension, the temperature, the sensibility of the abdomen, the presence or absence of unnatural tumours, or morbid growths within its cavity, the presence or absence of fluids, the nature and extent of the contents of the intestinal canal, may be ascertained with considerable precision by touch combined with pressure. Increase of temperature on the surface of the body is a most important sign of internal disease. Increase of temperature arises from a preternatural increase in the action of the arteries, and denotes inflammation of the part affected. All acutely inflamed organs are hotter than in their natural state, and if the inflammation be intense, the neighbourhood of the inflamed part gives to the hand of the examiner the sensation of pungent heat, which is always a sign not only of disease, but of exceedingly severe disease.

Diminished temperature, which arises from diminished action in the arteries, and an overloaded state of the veins, is no less important as a sign of disease. It always denotes a most dangerous condition of the system, the danger being in proportion to the coldness. It is the concomitant of the worst forms of fever which are ever witnessed in this country; fever with a cold skin being incomparably more alarming than fever with even a pungently hot skin. In that pernicious fever, of which we have lately had so much experience, termed cholera morbus, the first, the most sure, and the most alarming sign of the invasion of the malady, was coldness of the system, and especially of the abdomen, the main seat of the malady; and it was uniformly found that there was no one sign which afforded a better criterion of the extent of the danger, in any case, than the degree of coldness of the system in general, and of the abdomen in particular.

The physician may often form a judgment as to the seat, the nature, and the extent of abdominal disease, from the degree of sensibility of the abdomen to pressure with the hand; and, by practice, he may acquire such delicacy of touch as to be able to detect, by its means alone, morbid changes, even in deep-seated organs, to an extent, and with a degree of precision and certainty, far beyond what is commonly believed by practitioners.

3. That mode of external examination of the body termed percussion—namely, the mode of eliciting sounds from the surface, the nature of the sound produced affording a knowledge of the condition of the parts beneath, has opened to the modern practitioner a new source of information, the careful and skilful employment of which has afforded practical results of far greater precision and importance than could possibly have been anticipated. This mode of examination has been applied principally, and with the most valuable results, to the detection of the diseases of the chest; but application of it has recently been made, and not without very considerable advantage, to the detection of abdominal disease. M. Pierry, a young Parisian physician, has brought into a formal and matured shape this new application of a discovery of Anenbrugger, of which an excellent account is given by Dr. Forbes, in an article termed 'Exploration of the Abdomen,' in the *Cyclopædia of Practical Medicine.*

Our limits will not permit us to pursue this subject further. Our object has been rather to awaken than to satisfy curiosity; rather to indicate the nature and extent of the information to be acquired, than to supply it. Enough has been said to show that there is reason to congratulate both the medical profession and the public on the renewed attention which is now paid to the external or the physical signs of internal disease. The external examination of the body can never supersede other modes of investigation; but it may often afford essential aid to whatever other mode is adopted; and sometimes it is absolutely indispensable to the success of any other. With all the aids that can be applied to the task, the detection of internal disease is often difficult and very often uncertain, and the enlightened practitioner will gladly avail himself of every resource which is open to him, and will endeavour to derive from each the utmost information it can be made to afford.

The Father of Physic long ago said, 'Certain it is that he who examines the abdomen as well as the pulse, is much less likely to be deceived than he who does not.' And a distinguished modern, Baglivi, has confirmed this observation of Hippocrates in the following words:—'If physicians were always to examine the abdomen, upon first visiting the patient, more particularly in acute diseases, they would assuredly commit much fewer mistakes than they do at present, neglecting this method of exploration. The knowledge of the condition of the upper parts of the abdomen improves vastly both our treatment and our prognosis.'

ABDOMEN, in insects, has a somewhat different signification from the same term when applied to other animals, being used for the whole portion of the body of an insect behind the corselet (*thorax*), and including the back as well as the belly. It consists, in most cases, of a number of rings without any jointed members for locomotion, and uniformly incloses a portion of the intestines, though sometimes but a very small one. These rings, or very short hollow cylinders, are severally united with each other by a joint, by a membrane, or sometimes by an intimate junction, the exact line of which is not very apparent. The rings in some cases, as in the grub of the chameleon fly, slide into one another like the tubes of an opera-glass. Each ring is technically termed a segment (*segmentum*), virtually composed of two principal pieces, which, when distinct, are termed arches; the upper the arch of the back, the under the arch of the belly. In some cases these two portions are not distinct, but, when they are so, the two borders usually come into contact. When they do not, but remain free, one usually, more or less, overlaps the other as in bees. In caterpillars, grubs, and wingless insects, such as the flea, where the joining of the corselet with the abdomen is not apparent, the abdomen may always be known by the legs never being jointed with it; and in caterpillars it usually consists of all the body behind the six fore legs, which are always on the corselet.

ABDOMINALES, in Zoology, the name of a group of fishes, to which different naturalists have attached a more or less extensive signification, according to the particular principles of their several systems. The system of ichthyology (the knowledge of fishes) of Linnæus is founded upon the presence and position of the ventral fins (those of the belly) in relation to the pectoral (those of the breast); and these he justly enough regards as analogous to the fore and hind members of quadrupeds, and to the wings and feet of birds. Linnæus includes, in his order Abdominales, all those species which have the ventral fins placed behind the pectoral, or upon the abdomen, the cartilaginous fishes alone excepted; which, after the example of Ray, Willoughby, and Artedi, he very properly considers as forming an order apart. But this arrangement, though at first sight plausible, and apparently founded upon the modifications of important organs, is, in reality, extremely defective, and of little assistance in studying the natural affinities of fishes. The different nature of the medium in which these animals move, necessarily induces corresponding modifications in their organs of locomotion; and thus it happens, that the important functions of prehension and progression, which in birds and mammals are performed by the extremities alone, are executed by the tail; whilst the fins in fishes are of no further use than to balance the animal. These organs, and their different modifications, have, consequently, but a very slight influence upon the nature of fishes, compared with that which the extremities exercise upon land animals; and hence it is, that the Linnæan system of ichthyology, founded upon these modifications, fails altogether in arranging the different genera and species of this class of animals, according to these natural affinities.

M. Cuvier, perceiving the deficiency of the Linnæan system in this respect, revives the more correct and natural arrangement of Artedi; and after, first of all, dividing the class of fishes into the three great orders—Chondropterygii, Acanthopterygii, and Malacopterygii, according to the cartilaginous or osseous nature of their skeletons and fins, afterwards applies the principles of Linnæus, or the relative position of the pectoral and ventral fins, to subdivide the last of these orders into families. In its present acceptation, therefore, the term abdominales denotes a family, or subdivision of malacopterygious, or soft-finned fishes, only; and, in this restricted sense, includes the greater number of the fresh-water species, as well as those which, like the salmon, periodically migrate from the ocean to deposit their spawn in fresh-water lakes and rivers. M. Cuvier subdivides this family into five subordinate groups, all of which he has defined by appropriate and unequivocal characters. He denominates these subfamilies, cyprinoïdes, siluroïdes, salmonoïdes, clupeoïdes, and lucioïdes respectively, from the carps, silures, salmons, herrings, and pikes, the typical genera from which their characters are severally taken.

Salmon, given as a specimen of the family of Abdominales.

ABDUCTION (from *ab*, from or off, and *duco*, to lead) is an unlawful taking away of the person of another, whether of child, wife, ward, heiress, or women generally.

Abduction *of child.*—(See Kidnapping).

Abduction *of wife* may be either by open violence, or by fraud and persuasion, though the law in both cases supposes force and constraint. The remedy given to the husband in such a case is an action, by which he may recover, not the possession of his wife, but damages for taking her away; and also, by statute of 3 Edward I., c. 13, the offender shall be imprisoned for two years, and fined at the pleasure of the king. The husband is also entitled to recover damages against such as persuade and entice the wife to live separate from him without sufficient cause.

Abduction *of ward.* A guardian is entitled to an action if his ward be taken from him, but for the damages recovered in such action he must account to his ward when the ward comes of age. This action is now nearly superseded by a more speedy and summary method of redressing all complaints relative to guardians and wards,—namely, by application to the Court of Chancery, which is the supreme guardian of all persons under age in the kingdom.

Abduction *of heiress.* By a late statute, passed in the 9th year of George IV., the abduction of any woman against her will, who may have property either in possession or expectation, is declared to be a felony, and punishable by transportation for life or a shorter period, or to be imprisoned for any period not exceeding four years with or without hard labour. In addition to this punishment of the offender, the marriage, when obtained by means of force, may be set aside on that ground. In this case, as in many others, the law will construe *fraud* into force; and, consequently, in one case, where both the abduction and marriage were voluntary in fact, they were held in law to be forcible, the consent to both having been obtained by fraud.

Abduction *of women generally.* The forcible abduction and marriage of women is a felony. Here, and in the case of stealing an heiress, the usual rule that a wife shall not give evidence for or against her husband is departed from, for in such case the woman can with no propriety be reckoned a wife where a main ingredient, *i.e.* her consent, was wanting to the contract of marriage; besides which there is another rule of law, that 'a man shall not take advantage of his own wrong,' which would obviously be done here, if he who carries off a woman could, by forcibly marrying her, prevent her from being evidence against him, when she was perhaps the only witness to the fact.

ABEL, the second son of Adam. Some interpreters have maintained that he was the twin brother of Cain, but apparently without any authority from the language of Scripture. His history is contained in the fourth chapter of Genesis, where, we are informed, that he being a keeper of sheep, while Cain was a tiller of the ground, the two brothers offered sacrifices together to the Lord; the former bringing of the fruit of the ground for that purpose, and the latter of the firstlings of his flock. The offering of Abel alone was accepted; and the preference thus shown so excited the envy and anger of Cain, that, as they were together in the field, he rose up against his brother and slew him; thus for the first time staining the earth with human blood. There does not seem to be any reason for supposing that God was pleased with Abel's sacrifice, and offended with that of Cain, on account of the difference that there was between the offerings of which they were severally composed. It would rather appear that it was the opposite characters of the two brothers which made the sacrifice of the one acceptable, and that of the other the reverse. This view seems to be confirmed by the epithet which our Saviour applies to Abel in the twenty-third chapter of Matthew, *righteous* Abel; and also by the reason expressly assigned for Cain's enmity to his brother, in the third chapter of the First Epistle of John, where we are told that he slew him, 'because his own works were evil, and his brother's righteous.'

ABEL (CHARLES FREDERICK), a native of Germany, and a pupil of Sebastian Bach, was much distinguished as a composer and performer in the middle and towards the end of the last century. He served for some years in the celebrated band of the Electoral King of Poland, at Dresden; but, his talents being very inadequately rewarded, he quitted that service, in 1758, with only three dollars in his pocket, and reached England the following year, where he soon met with encouragement that did not end in empty praise. When the queen of George III. had her establishment fixed, Abel was appointed chamber-musician on it, at a salary of 200*l.* per annum; and shortly after he united with J. Christian Bach in forming a weekly subscription concert, which for many years continued to be highly patronised and liberally supported. His chief instrument was the *viol da gamba*, a small violoncello with six strings, now fallen into disuse. With this he produced an effect on his auditors which scarcely any one since has been able to achieve on bowed instruments, and principally by means of his *adagios*, or slow movements. 'His compositions,' Dr. Burney tells us, 'were easy and elegantly simple; for he used to say, "I do not choose to be always struggling with difficulties, and playing with all my might." In nothing was he so superior to all other musicians,' the historian of Music adds, 'as in writing and playing an *adagio*, in which the most pleasing yet learned modulation, the richest harmony, and the most elegant and polished melody, were all expressed with such feeling, taste, and science, that no musical production or performance with which I was then acquainted seemed to approach nearer perfection.' (*Hist. of Music*, vol. iv.) The critic, however, of the present day, who has compositions of the same kind by Haydn, Mozart, Beethoven, Clementi, Dussek, and Cramer, &c., fresh in his memory, will not deny the vast superiority of these later productions. Abel—judging him by his remains—possessed more taste than imagination—more knowledge of his art, and elegance in his manner of performance, than vigour of conception. Even Dr. Burney admits that 'his later productions, compared with those of younger composers, appeared somewhat languid and monotonous.' But we suspect the fact to be, that they were more accurately estimated when compared with the productions of a more advanced age. Abel was intemperate in the use of fermented liquors, and brought his life to a hasty close in the year 1787.

ABEL (NIELS-HENRI), born 1802; died 1829; aged twenty-six years and a-half. If we cannot place him in the first rank of analysts, it is because his early death prevented his competing with the great names of the age in that department in the *quantity* of his labours. But his first essays, compared with those of the best mathematicians, sufficiently indicate a talent which would have placed its possessor high in the ranks of science. He was born in the province of Christiansand in Norway, where his father was a poor clergyman. He commenced his studies at the cathedral school of Christiania, and at the age of sixteen showed a decided turn for scientific pursuits. In 1821 he entered the university, and soon afterwards published his first essay. In 1824 the government gave him an allowance of 600 dollars, to enable him to travel. He went, accordingly, through France, Germany, and Austria, and formed an acquaintance with M. Crelle, in whose journal, and in the *Astronomische*

Nachrichten of Professor Schumacher, most of his works are published. On his return, after two years of absence, he was appointed Professor in the University, which post he held till his death, which was brought on by over-exertion in his public duties.

Abel has linked his name to a remarkable discovery. It is well known that no *general* solution has ever been discovered of any class of equations above the fourth degree,—that is, no problem has hitherto been solved, in which the quantity sought has been multiplied by itself more than three times, in the conditions of the question. Some particular cases only have been fully investigated, and though all can be solved with more than sufficient nearness for practical purposes, yet a general and exact solution has never been found. Abel showed that such a solution never could be found, that the roots of an equation of the fifth degree and upwards did not admit of any general algebraical expression.

While the researches of Abel on elliptic functions excite the attention of all mathematicians, the elementary student may judge of the elegance of his analytical style, from a paper on the convergence of series in Crelle's Journal, in which some results, hitherto unnoticed, seem to lie on the very threshold of the subject. M. Crelle calls him, with justice, one of those geniuses who appear but once in a century.

A collection of his works is preparing for the press; but where, we are not informed.—[See *Dictionnaire de la Conversation et de la Lecture*, No. I., 1832.]

ABELARD, one of the most celebrated teachers of the twelfth century, both for his extraordinary talents and his misfortunes, was born at Palais, a little town in the neighbourhood of Nantes, in the year 1079. His father, a gentleman of fortune, and of considerable merit, spared no expense for the education of his son. Learning, having begun to revive a second time in the preceding century, had made considerable progress in France towards the end of the eleventh; and Brittany was not behind the general improvement. The far-famed Roscelin was from that country, though he was not the master of Abelard, as many writers have asserted.

But Brittany, fruitful as she was in celebrated teachers, was soon too narrow a field for Abelard, who had already learnt Hebrew, Greek, and Latin; and accordingly he went to Paris, whose University was the resort of crowds of students from all parts of Europe. Guillaume de Champeaux, the most skilful dialectician of the age, numbered Abelard among his pupils. But the pupil soon surpassed his master, and in the dialectic struggles of the day, he often challenged him to public disputations, so common in the twelfth century, in which the youthful pupil frequently vanquished his more tried and experienced antagonist. After this success, he became so puffed up with vanity, that he made enemies of all around him. His tutors, and many of his fellow pupils, became disgusted with him, and Abelard retired to Melun. But even here the anger of his exasperated master brought him into many troubles; in spite of which, however, a great number of pupils left De Champeaux to attend the lessons of the rival professor at Melun. This success induced Abelard to change his residence, and to remove nearer Paris, as the storm was now somewhat abated. But his arduous labours had so much injured his health, although he was then scarcely twenty-two years of age, that he was obliged, for some time, to discontinue his public lessons, and to seek, by repose, and breathing his native air, to restore his declining constitution. After the lapse of some years, he came back to Paris, where he found that his powerful antagonist had ceded his chair to a man of very inferior talents, who was all at once deserted by his pupils on the re-appearance of Abelard. This unforeseen circumstance forced De Champeaux to enter again into the arena, there to dispute with this scholastic Achilles, by whom he was again conquered, and compelled for ever to leave the field. Family affairs obliged Abelard to withdraw from the scene of his triumphs; and his conquered rival was at the same time appointed to the see of Châlons-sur-Marne. In consequence of this event, Abelard, at his return, did not resume his dialectic lessons: he went to Laon, in order to study divinity there, under the direction of Anselme; but his pride and his vanity having led him to commit the same faults there which he had committed at Paris, he suffered nearly the same severe consequences. The disciple of Anselme put himself forward as the master: taught divinity to the pupils, and, still more, taught them to despise Anselme; who, indeed, was unfit for his station, and altogether inferior to Abelard. The latter compared him to a tree of promising appearance at a distance, on account of its thick foliage, but whose nearer view disappoints us, when we find it bears no fruit. [*Abel., Epist. prima.*] However, Anselme had power enough to have him expelled from Laon, which he soon effected. Abelard now re-appeared in Paris, but as professor of divinity, and in a few days he was better attended by pupils than when previously most successful. He saw himself surrounded by the most eminent scholars of his age: Gui du Châtel, who became Pope Celestin II.; the still more famed St. Bernard; and above all, the illustrious John of Salisbury. Enriched by this extraordinary success, and intoxicated by his fortune, he now gave way to passions of a different kind. He cast his eyes on the fair Heloise, niece of Fulbert, a canon in the cathedral of Paris, and from that moment he thought of nothing but seducing her. In order the more readily to accomplish his ends, he proposed to the unsuspecting uncle to receive him into his house as a boarder, and he promised to give, in exchange, all the instruction which he might consider his niece to require. The canon, who was anxious that Heloise should be a star amongst the learned of the age, and who was rather parsimonious, was delighted to see his ardent wish likely to be accomplished, and that, too, without expense. It was exactly as if, according to Abelard's own words, the 'shepherd himself had introduced the wolf into the fold.' Amongst the things taught by Abelard to his ardent pupil, the art of love was the chief; and very soon the fair disciple surpassed her master. Their love was published all over Paris, before the good canon suspected anything wrong; but the negligence of Abelard in attending to his scholastic duties, excited so generally the satirical clamours of the students, and became so universally the topic of conversation at Paris, that at last the eyes of the uncle were opened to the consequences of his indiscretion. His niece, whose shame could no longer be concealed, fled to Brittany, and hid herself under the roof of Abelard's sister, where she gave birth to a boy, who was called Astrolabus; but the child died. Fulbert, enraged at this discovery, demanded the marriage of Heloise. Abelard, although ordained, yielded to his threats, as did Heloise herself, but with a great deal more reluctance. She seems to have been not so much actuated by any improper motives (as so many romantic writers, who have disfigured history, under the pretext of embellishing it, have been pleased to repeat), as because she thought that this union, being made public, would infallibly ruin the fortune of Abelard, and destroy that which was above all things dear to her—the present and future glory of her illustrious lover. She wrote a letter to Abelard, to dissuade him from the marriage, which is full of the most eloquent expressions. At last it was agreed that the marriage should be performed at Paris, and kept secret. But Fulbert, who was impatient that the honour of his family should no longer be the subject of public scandal, lost no time in making the marriage as public as possible. Heloise, convinced that the glory of her husband was endangered by their marriage being known, denied it in the strongest manner. Her uncle, enraged at her obstinacy, in which he thought her encouraged by Abelard, swore to revenge himself at least on his niece, who was at that time residing with him. Abelard, being informed how cruelly Heloise was treated by Fulbert, took her away, and placed her in the convent of Argenteuil, near Paris. Fulbert, believing that Abelard wanted to make a nun of his wife, in order to get rid of a mistress, vowed a cruel vengeance, which he was soon enabled to execute. He bribed the valet of Abelard to admit two wretches into the bed-room of his master at midnight, who mutilated him in the most atrocious manner. The miscreants were punished after the cruel fashion of the age; and the canon was condemned to lose all his fortune, and was banished from Paris. Heloise took the veil at Argenteuil, and Abelard went to bury his grief and his shame under the monastic garment in the Abbey of St. Denis. But he did not there find the repose which he sought. The monks of that convent soon hated him, on account of the freedom with which he reproached them for their dissolute habits, and for his having had the temerity to assert, and to prove, that their great patron, St. Dionysius, or St. Denis, was not the Areopagite, who was then as generally believed to be the patron of that church, as the reverse is now universally known to be the fact. But this opinion of his, well-founded as it was, shocked the prejudices of the monks, being contrary to the legends and miracles of the abbey, and, as such, was considered as subversive of the privileges of the order. The infatuated monks, enraged at the pretended heresy of his work on the Trinity, which was publicly burnt in council at Soissons, in 1121, and still more at his 'treacherous' assertions about St. Denis, accused him to the king of high treason.

To escape from the impending danger, the unfortunate Abelard fled, and took refuge near Troyes, placing himself under the protection of the Count of Champagne, that country being then independent of the crown (*Du Cange*), as to judicial power. Here he built the celebrated Oratory of Paraclet, where a number of pupils came again to him in his solitude, and prevailed on him to resume his lectures. Amongst these pupils came two furious fanatics, whom his enemies had incited against him, and who soon discovered fresh theological errors; this provoked his enraged calumniators to still further persecution of Abelard, till, about this time, the monks of the Abbey of Bruis, near Vannes, in Brittany, elected him their superior. But here again, as at St. Denis, his endeavours to establish order, and to suppress the licentiousness which prevailed in that monastery, drew on him the implacable hatred of the monks, who, having first tried to ruin his character by calumny, afterwards even attempted his life by poison. Heloise also was not without her share of troubles; for she was expelled, with the rest of the nuns, from the convent of Argenteuil, on account of the scandalous disorders which prevailed there, although, notwithstanding the calumnies which were circulated against her, she had conducted herself with the strictest propriety.

In this destitute condition, Abelard gave her the Oratory of Paraclet; and after eleven years of separation, saw her there at the consecration of the community. Her exemplary conduct procured her general admiration, and particularly that of the bishop; while Abelard himself governed the convent by his occasional visits, by his advice, and by his letters, which are still preserved, and which very curiously prove that he encouraged the nuns not only to acquire a thorough knowledge of Scripture, but also to study the Hebrew, Greek, and Latin languages, in which Heloise had the reputation of being a proficient. Heloise's love being, as was suspected, by no means extinguished, notwithstanding her having taken the veil, the visits of Abelard to the Paraclet gave rise to some scandal. Being still accused of heresy by his inveterate enemies, at the head of whom was St. Bernard, he resolved to defend himself in full council, which he accordingly did at Sens. The king, Louis VII., was desirous of being present, to hear the defence of so distinguished a man. Notwithstanding his eloquence, he was condemned in 1140, as he had been before in 1121. Persecuted, it may be said, rather for his boldness and freedom of thought, than for his errors in theology, he desired to appeal to the pope, and on his way to the pontiff, was stopped at Cluni, near Maçon, by Peter the Venerable, who tried to soothe his grief, and to appease his enemies. Shortly afterwards he became reconciled to St. Bernard; and consigning himself, for the rest of his life, to the closest retirement, he died two years after, in 1142, at the Priory of St. Marcel, having, by his sincere repentance, his resignation, and good conduct, excited the admiration of the monks and the clergy of France. He was buried at Paraclet, and the remains of Heloise were interred in the same tomb, twenty-one years after. This beautiful gothic tomb was removed to Paris in the year 1800, and placed in the cemetery of Père la Chaise in 1817, where it is now to be seen.

In Abelard's time, scholastic instruction was divided into two courses: the one, the 'trivium,' containing grammar, rhetoric, and dialectics or philosophy; the other, the 'quadrivium,' comprising arithmetic, music, geometry, and astronomy. Abelard understood all these sciences in the greatest perfection, for his time, and thereby obtained from his contemporaries the title of the all-accomplished master. He was considered to be the only person who understood the writings of Aristotle, which had been unknown in France until the preceding century, when they were communicated through the learned Jerbert, who, travelling in Spain, had learnt them from the Arabians. Notwithstanding all that has been said of Abelard's perfect knowledge of the writings of Aristotle, it is now well ascertained that the Greek text did not exist at that period in France, and that there were only partial Latin translations from the Arabic. All the quotations of Abelard from Aristotle, in every part of his works, are invariably in Latin, as well in the printed edition of Abelard as in the three different MS. copies which we have seen of his works in the British Museum.

In estimating Abelard's acquirements we must judge of them by the age in which he lived. Scholastic philosophy and theology were then the highest branches of learning, and it was Abelard's praise to have surpassed in these all his contemporaries. If we are to judge of this renowned disputant by what remains of him, we fear our judgment would be rather unfavourable. Among the Lansdowne MSS. of the British Museum the reader may see a copy of two of Abelard's dialogues, one between a Christian and a Jew, the other between a Christian and a philosopher. Words are wanting to express the utter insipidity and absence of all taste, energy, or life, which these spiritless compositions display; nor can we concede to them the praise of being written in Latin which will bear the test of strict examination. The crime of Abelard, for such we must call it, and his misfortunes, have given to his name a celebrity, to which we conceive most men would prefer an honourable obscurity. Pope's well-known epistle of Heloïse to Abelard, which is animated with the glowing fervor of the unfortunate lovers, while it is tainted with the impure imagination of the poet, has made the name of Abelard familiar to those who are, perhaps, only imperfectly acquainted with his true history.

The real historic interest of Abelard's life turns on the state of knowledge during the age in which he acquired his reputation. The works of Abelard were once thought worthy to be put in the Index by the Inquisition of Madrid, which is almost the only thing we know in their favour. As to the question whether Abelard himself knew Greek, we are inclined to think that he did to a certain extent, but whether he was well acquainted with any Greek authors, except perhaps the New Testament, seems to us doubtful. That he knew some parts of Aristotle and Plato, both of them probably through translations, is pretty certain. In the printed edition of Abelard's works (1616) a few Greek words occur here and there(pp. 241, 244, 247, 831), which, taken in connexion with the remarks upon them, undoubtedly prove, if these passages really were in his MSS., as we believe they were, that he must have had some knowledge of the Greek language. It appears that Greek was always studied in France during the ninth, tenth, eleventh, and twelfth centuries; though it was very imperfectly known, and confined to a few schools. Hebrew and Arabic, at that time, were both better known than Greek. The occasional visits of Greek priests into Western Europe served to keep alive a certain degree of knowledge of this language.

The most complete edition of Abelard, is *Petri Abælardi et Heloisæ Conjugis ejus Opera, nunc primum edita ex MSS. codd. Francisci Amboesii.* Paris, 1616, in 4to.

The edition in the British Museum, though it is in fact that of Amboise, bears the title of *Andreæ Quercetani* (Andrê Duchesne), as do several other copies. Andrè Duchesne is the author of the Notes and Commentaries at the end. There is a number of other editions, amongst which is that of the Letters published by Bastion, 2 vols. 12mo, Paris, 1782, with the text and translation; that of Fournier, 1796, with a Life of Abelard, by M. Delaunay, 3 vols. 4to.; that of Richard Rawlinson, London, 1714, 8vo.; that of Oxford, 1728. Brunet, in his Manual, gives an incomplete list of them.

The principal sources from which we have drawn this article are, first, the *Literary History of France*, from page 20 to 225, vol. ix.; *Bayle's Critical Dictionary* (Amsterdam edit.), 1740, 4 vols. folio; the *Universal Biography*; and the *Works of Abelard*, complete, Paris, 1616, 4to.

ABELE TREE, in Botany, the English name of the Populus alba.—(See POPULUS.)

ABELMOSCHUS, in Botany, a genus of the Mallow tribe, usually referred to *Hibiscus*, which see. It consists of plants having showy white, rose-coloured, or yellow flowers, with a rich deep purple or brown centre. The name is an alteration of the Arabic *habb êl misk*, or musk-seed, according to Forskahl.

ABENCERAGES, is the name given by Spanish chroniclers and romance writers to a noble family in the Arabic kingdom of Grenada, several members of which distinguished themselves during the period immediately preceding the fall of the Mohammedan empire in Spain. The history of the Abencerages is intimately connected with that of the then reigning dynasty of Grenada. In the year 1423 of our era died Yussuf III., a wise and valiant prince. He was succeeded by his son Mohammed VII., surnamed Al-Haizari, or the Left-handed, who followed the example and advice of his father in maintaining friendly relations with the Christian court of Castille, and with the Arab princes on the northern coast of Africa, but lost the affection of his subjects by his pride and tyranny. The discontent which soon manifested itself against the youthful monarch, was for a time kept in check by the watchfulness of his principal chamberlain Yussuf ben Zerragh, then the chief of the noble family, which probably derived from him the common designation of the Abencerages. But, in 1427, an open revolt broke out, which had been incited by one of the king's cousins, Mohammed al Zaghir. The royal palace, called the Alhambra, was invested by the conspirators. Mohammed VII., disguised as a fisherman, escaped to Africa, where the King of Fez, Mulei ben Fariz, kindly received him, while Mohammed al Zaghir ascended the throne of Grenada. Yussuf ben Zerragh, with most of the Abencerages, fled from his persecutions to Castille; and some members of the family who had remained at Grenada were put to death. John II., then King of Castille, yielding to the representations and entreaties of Yussuf ben Zerragh, negociated through him a treaty with the King of Tunis, to replace Mohammed VII. on the throne of Grenada. This plan succeeded. Mohammed VII., supported by his two allies, recovered his paternal dominions, and Al Zaghir suffered death for his treason. But the friendly relations between Grenada and Castille were soon interrupted, in consequence of the refusal of Mohammed VII. to fulfil certain engagements which he had entered into with John II. Hostilities broke out, and John declared himself in favour of Yussuf ben Alhamar, an aspirant to the throne, who had formed a strong party in the kingdom of Grenada. Yussuf ben Zerragh led the troops of Mohammed VII. to encounter the united forces of his opponents. But he fell in a decisive battle, which he lost, and Yussuf ben Alhamar occupied Grenada, while Mohammed VII. fled to Malaga. This second interruption of Mohammed's reign was, however, only of short duration. He regained his throne a second time after the death of Yussuf ben Alhamar, which took place within six months. Fresh hostilities with Castille soon commenced. The frontier provinces of Grenada were much infested by the incursions of the Castilian commander Cazorla. A son of Yussuf ben Zerragh, at the head of a select band of valiant knights, drew out his troops against Cazorla, and fell in a battle (1438), in which the Castilians sustained much loss. New disturbances soon broke out in the interior of Grenada. Mohammed VII. was (in 1444) once more dethroned by one of his nephews, Osmin al Ahnaf. But the claims of the latter to the throne were contested by another aspirant, Mohammed ben Ismaïl, who was supported by John II.; and, finally, in 1453, prevailed over his opponent. Soon after this, John II. was succeeded in the government of Castille by Henry IV., who was adverse to Mohammed ben Ismaïl, and renewed the hostilities which, from this time, took a turn decidedly unfavourable to the kingdom of Grenada. The Spanish historians mention that, about this time, an attempt at a revolution was made in Grenada by the Abencerages, which had for its object to confer the crown on one of their own family, Mohammed ben Zerragh, and that the Castilian commander, Medina Sidonia, took advantage of these disturbances to occupy the fortress of Gibraltar. The Arabic chronicles say nothing of such an event, and the whole story appears doubtful. If there be any truth in the report, it may be, that the Abencerages made another effort to place Mohammed VII. once more upon the throne, which, from their steady attachment to the cause of that unfortunate prince, seems not improbable.

Of the feuds of the Abencerages with the Zegries, another noble Arabian family in the kingdom of Grenada, who traced their descent from the Mohammedan kings of Cordova, of the massacre of thirty-six Abencerages, caused through the perfidy of their opponents, and how the survivors of the family ultimately embraced the Christian religion, and entered the service of Ferdinand of Castille, a highly interesting story is told in the *Guerras civiles de Granada*, by Gines Perez de Hyta, a work which professes to be a translation from an Arabic manuscript. Of the authenticity of this there seems, however, good reason to doubt. The work properly consists of two volumes, but in most editions only the first is reprinted, and copies of the second are said to be now extremely rare even in Spain. An English translation of the first part, by Thomas Rodd, appeared under the title of *The Civil Wars of Granada*, &c. London. 1803. 8vo. [See *Conde's Historia de la Dominacion de los Arabes en España*, vol. iii.]

ABEN ESRA, sometimes called Ebenare, or Evenare, by the scholastic writers, or with his complete name Abraham ben Meïr ben Esra, was a celebrated Jewish scholar, who lived during the twelfth century. The year of his birth, as well as that of his death, is unknown. He was born at Toledo, probably in A.D. 1093, and died, it is believed, about 1168, at an age of seventy-five years, or upwards. Of the history of his life, few details are known. The Rabbi Japhet Hallevi is mentioned as having been one of his early teachers. A considerable portion of his life was spent in travelling. He visited Mantua in 1145, and the island of Rhodes in 1156; in 1159 he was in England, and in 1167 we find him at Rome. His celebrity, even among his contemporaries, as a scholar, and as an accomplished writer of the Hebrew language, was very great. Moses Maimonides recommended his son to study the writings of Aben Esra in preference to all others; and the well-known grammarian, David Kimchi, and the traveller, Benjamin of Tudela, praise his vast erudition; while Juda ben Alcharizi, the successful Hebrew translator and imitator of Hariri, acknowledges his merits as a poet. Among ourselves Aben Esra has become known chiefly through his great commentary on the Old Testament, which, it seems, he wrote at different periods, between the years 1140 and 1167. It has been printed in the great Rabbinical editions of the Bible, which have appeared at Venice, Bâle, and Amsterdam, and there have been besides many separate editions of single parts of it. But, from the great number of his other writings, which are still extant, it is evident that Aben Esra must have bestowed as much attention upon mathematics, astronomy, philosophy, and medicine, as on philology; and his treatise in verse on the game of chess (edited by Thomas Hyde, Oxford, 1694) affords us a specimen of his success in poetic composition. For an enumeration of the works of Aben Esra, which are still preserved in MS. in several of the libraries of Europe, see the article 'Aben Esra,' by Hartmann, in *Ersch und Gruber's Encyclopædie*, vol. i.

ABER. This word, which is prefixed to the names of many places in Great Britain, is a Celtic term, and means, generally, the mouth or entrance of a river. It is sometimes defined as 'the fall of a small water into a greater,' which, of course, *includes* the terms 'mouth of a river,' and 'port or harbour.' Thus, the town of Aberbrothwick, in Scotland, is at the mouth of the river Brothick, and New Aberdeen is near the mouth of the Dee. In Wales, we have Abergavenny, at the confluence of the Usk and Gavenny; and Aberystwith at the outlet of the river Istwith.

ABERBROTHWICK, or more commonly ARBROATH, a town in Scotland, in the county of Forfar, at the mouth of the rivulet Brothic, from which its name comes. It is a royal burgh, having been created so by charter, granted in 1186, and renewed in 1589; and, in conjunction with Aberdeen, Montrose, Bervie, and Brechin, formerly sent one member to parliament. Aberbrothwick is now united with Bervie, Brechin, Forfar, and Montrose in sending a member. It is irregularly built, except in the parts of modern erection. The town-house contains several public offices, as well as a library and reading-room. The chief manufactures are sail-cloth, thread, and leather, which are exported, together with paving-stones and grain. Among the imports are flax, hemp, linseed, and tallow. A small but secure harbour (defended from the sea by a breakwater, and protected by a battery of twelve guns) enables the town to carry on this trade. There are two parish churches, and some dissenting places of worship. The population amounted in 1831 to 6660. There are the ruins of an abbey, founded in honour of St. Thomas-à-Becket, which was destroyed by the reformers in 1560. The last abbot was the celebrated Cardinal Beaton. Aberbrothwick is fifty-eight miles north-north-east of Edinburgh. Lat. 56° 32′ north, long. 2° 34′ west.

ABERCROMBY (SIR RALPH), a British general, distinguished for many gallant and important services. He was the son of George Abercromby, Esq., of Tullibodie, in Clackmannanshire, where he was born in 1738. After receiving a liberal education, he entered the army in March, 1756, as a cornet in the 3d regiment of Dragoon Guards. By the year 1787 he had reached the rank of major-general. When the war with France broke out, in 1793, Abercromby was sent to Holland, with the local rank of lieutenant-general, in the expedition commanded by the Duke of York. His bravery during the prosperous commencement of this attempt was not more conspicuous than the humanity with which he exerted his best energies in the disastrous sequel to alleviate, as far as possible, the miseries of the sick and wounded troops, whom he was charged to conduct in their retreat.

Soon after his return to England, in April, 1795, he was made a Knight of the Bath; and in August of the same year, he was sent out to the West Indies, as Commander-in-Chief of the forces there. In this quarter he took from the enemy, in succession, Grenada, Demerara, Essequibo, St. Lucia, St. Vincent, and Trinidad. The last of these colonies fell into his hands in February, 1797. He then returned to Europe, having been previously raised to the rank of lieutenant-general; and on reaching England, he was rewarded for his valuable services by receiving the command of the Scots Greys, and the appointment of lieutenant-governor of the Isle of Wight. In the following year, on the breaking out of the rebellion in Ireland, Sir Ralph proceeded thither, as commander-in-chief; but after he had held that office for a short time, it is understood that his unconcealed aversion to the service in which he was engaged, and some differences of opinion with his superiors as to certain operations, led to a new arrangement, by which he was transferred to the chief military command in Scotland, and the governorship of Fort Augustus and Fort George. He was soon, however, called again to active service abroad, on occasion of the second expedition sent against the French in Holland, in August, 1799, with the conduct of which he was entrusted, before the arrival of the Duke of York. It proved, as is well known, equally unfortunate with the former; but it did not the less afford many opportunities to General Abercromby of displaying his activity, intrepidity, and high military talent. In 1801, he was employed to command the English forces despatched for the relief of Egypt; and, in spite of the utmost exertions of the French to prevent his design, he effected the landing of his troops, on the 8th of March, at Aboukir, though not without the loss of 2000 men. A few days after, the enemy made a general attack upon the invading forces, as they lay encamped near Alexandria, but were speedily repulsed. On the 21st, was fought, on the same ground, the more obstinate and bloody engagement, usually designated the battle of Alexandria, in which the French were again driven back at all points. But the victory of our countrymen was purchased at the cost of the life of their gallant commander, who was unhorsed and severely wounded at an early period of the action, by one of the enemy, whom, notwithstanding, he disarmed, delivering his sword to Sir Sidney Smith, whom he soon after met. Then remounting his horse, 'he concealed his situation,' says the despatch of Lord Hutchinson, 'from those about him, and continued in the field giving his orders with that coolness and perspicuity which had ever marked his character, till long after the action was over, when he fainted through weakness and loss of blood.' The injuries which he had received, and which he thus nobly bore in silence, were past the skill of surgery: he was immediately conveyed to the ship of the Admiral, Lord Keith, and there lingered till the 28th, when he expired. His body was interred in the burial-ground of the Commandery of the Grand Master, under the walls of the Castle of St. Elmo, near the town of La Valetta, in Malta. A monument has since been erected to his memory, by order of the House of Commons, in St. Paul's Cathedral. Sir Ralph Abercromby, whose private character was as excellent as his public merits were great, left four sons, of whom the present Lord Abercromby is the eldest. On his death, his widow was created Baroness Abercromby, with remainder to her issue male by her late husband. A pension of 2000*l.* a year was also settled upon Lady Abercromby and the three succeeding inheritors of the title.

ABERDEEN. This name is common to two places situated very near to each other, between the rivers Don and Dee, on the eastern coast of Scotland, and in the shire of Aberdeen. They are often confounded, though they are distinct, both in their municipal and ecclesiastical constitutions.

Old Aberdeen, the more northerly of the two, on the right bank of the Don, was only a village (though said to be of some note) until the twelfth century; when it was elevated to the rank of a city by the removal to it of the bishopric of Morthlac, in Banffshire. The cathedral of St. Machar is now nearly demolished; a small part only being retained for the celebration of divine service. There is also a neat town-house, erected towards the close of the last century, and a bridge of one Gothic arch, built by Bishop Cheyne, in the early part of the fourteenth century, up to which bridge the river Don is navigable. There are some small charitable foundations; but the University (King's College) is the institution most deserving notice. This is not to be confounded with Marischal College, in New Aberdeen, for they are not under the same management, and all attempts to unite them have proved vain; although, in some things, their respective directors may co-operate. King's College was founded by James IV. in 1494, in which year he received the pope's bull for its institution, and it was opened for the reception of students some time previous to 1506, Bishop Elphinstone having in the interval greatly aided also in its establishment. It possesses a library of nearly 13,000 volumes,[*] and can claim, from the Stationers' Company of London, a copy of every book entered at their hall. There are also 134 bursaries or endowments for the support of students, varying from under 5*l.* to 50*l.* per annum. The number of students in 1826 was 235. In the College Chapel, the body of the founder is deposited. The population of Old Aberdeen has probably increased, as that of the parish, which extends considerably beyond the city, had risen, between 1821 and 1831, from 18,312 to 25,017.

New Aberdeen, though often called a city, either from its importance, or from its being confounded with the place last mentioned, is only a royal burgh; having, at the head of its corporation, a provost and four baillies. It is now united with Old Aberdeen in the return of a Member to Parliament. It stands on a rising ground, or rather upon four small eminences, on the north or left bank of the Dee, which forms its harbour, and over which is a fine granite bridge of one arch, having 132 feet span. The town-house, the prison, and a Masonic lodge are united in one building, in the middle of which is a tower with lofty spires. In this building is the town armoury, and an instrument for beheading, similar to the guillotine, termed a Maiden. The Bridewell was built in 1819, and has five floors, with a garden, and areas or yards: each convict has two apartments. There are also military barracks for above 500 men, and a theatre open for three or four months in the year. There are seven places of worship of the establishment,—namely, five chapels of ease and two kirks: these last are under one roof. The east kirk is an ancient Gothic structure, with a tower and five bells; the west kirk is of more modern architecture. There are, besides, many dissenting places of worship, whereof four belong to the Seceders, three to the Episcopalians, and the remainder to the Baptists, Methodists, Catholics, and other religious denominations.

There is a poors'-hospital, behind the town-house, enriched in the course of years by various benefactions, from which 400 aged poor receive allowances, and by which forty children are maintained and educated. Gordon's Hospital, endowed by Robert Gordon, a burgess of Aberdeen, in 1729 and 1730, receives and educates eighty-four boys in several branches of useful knowledge.[†] There are some other charities.

Marischal College takes its name from George Keith, Earl Marischal, who founded it near the close of the sixteenth century (1593 or 1594). It is an irregular building, in the north-east part of the city, and contains a museum, a philosophical apparatus, and an observatory elevated sixty feet above the court in which it stands. The library consists of 10,000 volumes, although this University is not entitled to a copy of every work published for sale; like King's College, which is, indeed, regarded as a depository for both these Universities. The number of students in the session 1816-1817, the latest period of which we have been able to obtain an account, was 220, besides 105 divinity students, attending alternately here and at King's College. There are here, also, 106 bursaries, which attract to Aberdeen many indigent students.—[See *Journal of Education*, Nos. 7, 8.]

The manufactures of Aberdeen are woollens, linens, and cottons, especially hosiery, though this last branch of industry was much depressed in the late war. Coarse yarn is exported as such, or worked up into canvas, sail-cloth, sheeting, &c.; and the printed cottons are in considerable repute for quality and colour. Thread, carpets, and coarse cloths; nails, cordage, and materials for ship building, are also among its productions. These articles, with granite, (of which 7000 tons, for paving, are sent yearly to London,) salmon, (caught in the Dee and Don,) and grain, are the chief exports; and, in return, besides articles of ordinary consumption, they bring in wool from London and Newcastle, flax from different parts of England and Holland, and coals from England and the Firth of Forth. There are some breweries in the town, as also iron founderies, and ship-building yards, at one of which several steam-vessels, of between 500 and 600 tons, have been fitted out.

---

[*] This is, at least, as far back as 1818.

[†] The statement of the number of persons receiving the benefit of these charities is from the *Edinburgh Gazetteer*, published in 1827. Such numbers are liable, of course, to fluctuation.

The harbour is spacious and safe; and a pier, erected under the direction of the celebrated Smeaton, and subsequently lengthened, has caused a diminution of the bar which once obstructed the entrance, so that vessels drawing seven or eight feet of water can enter at any time. By a parliamentary return of 1830, it appears that 350 vessels, with an aggregate tonnage of 46,201, belonged to the port. There is a navigable canal, eighteen miles in length, from this place to the bridge over the Don at Inverury.

An English garrison, which occupied the castle in the beginning of the fourteenth century, having been cut off by the townspeople, the fleet of Edward III. attacked and devastated Aberdeen in 1333; and a victory gained over an English detachment at Dunottar drew down a more complete destruction from Edward's army in 1336. It was on its being rebuilt after this calamity, that the designation of New Aberdeen was bestowed. Many of the citizens were slain in the defeat which the Covenanters suffered from Montrose in 1644.

New Aberdeen is 108 miles N.N.E. of Edinburgh, and 425 N. by W. of London; lat. 57° 9′ N., and long. 2° 8′ W. of Greenwich. The population of the burgh and parish, in 1821, was 26,484; by the last returns in 1831 it had increased to 32,912.

ABERDEVINE (*Carduelis spinus*, Cuvier; *Fringilla ligurina*, Ranzani), sometimes called the siskin, a well-known song-bird, which has some resemblance to the green variety of the canary-bird, but there is considerable difference in individual birds with respect to the brightness of colouring. Fleming's specific description, therefore, 'the head above, black; the neck, breast, and rump, lemon yellow,' though it applies to individual male birds, will not apply to others, and not at all to the female; as we have seen male birds, at least two years old, with the head grey rather than black; and others with neck, breast, and rump as bright yellow as the marks on the wings of the goldfinch. In the latter instances the head was jet black.

Syme conjectures that if the aberdevine is not the original stock-bird of the cage-canary, it is very similar to it, and ought to be considered rather a variety than a distinct species; but if he had looked closely at the points of the bills, the lengths of the tails, and particularly at the motions and manners of these several birds, we think he would have come to a different conclusion.—[See Canary.]

Sepp has delineated the nest of the aberdevine in the cleft of an oak, built with dry bent mixed with leaves, and profusely lined with feathers; the base neatly rounded, and the feathers projecting above the rim, and concealing the eggs, which are bluish-white speckled with purplish red, like those of the goldfinch. Temminck, again, says it builds in the highest branches of the pine.

It breeds in the north of Europe, and only visits Britain, Germany, and France in the autumn and winter. It is represented in some books as very irregular in its migrations, particularly to this country; but we suspect that this opinion has perhaps arisen from the irregularity of observations, for, since our attention has been directed to the subject, we have remarked its arrival about Lee, in Kent, to be almost as regular as the departure of the swallows, which takes place about the same time. During its winter stay with us, the aberdevine feeds chiefly on the seeds of the birch and alder.

As a cage-bird it is frequently paired with the canary, to produce what are termed mule-birds; but it is, besides, a lively and persevering songster. One which we possessed, though the colours were so dull as scarcely to distinguish it from a hen-bird, sang for ten or eleven months in the year. Its song would be very pleasing, though not so plaintive as that of the linnet, nor so sprightly as that of the goldfinch, if it did not at intervals introduce a jarring guttural note, almost like the croak of the nightingale when angry.

ABERGAVENNY, a town in the county of Monmouth, at the confluence of the Usk and Gavenny, situated in a range of meadows, surrounded by several hills. There is a fine old bridge, of fifteen arches, over the Usk; also an ancient and spacious church, as well as the remains of a castle, and of a Benedictine priory founded soon after the Conquest. The town is long and straggling, the streets narrow, and the houses irregularly built; but considerable improvements have been made by enlarging the market-place and removing projections. There are several Dissenting meeting-houses, a Catholic chapel, a grammar-school, a Lancasterian, and several Sunday schools. The principal trade is in wool, of which a considerable quantity is sold in the market in the months of June and July. The supply of coal and iron afforded by the neighbouring mountains has given rise to several iron-works in the surrounding district. The population in 1831 was 4230. The Monmouthshire and Brecon canal passes near the town, and gives facilities for its trade and that of the neighbourhood. Abergavenny is supposed to have been the Roman station of Gobannium, so called from the river Gobannius (Gavenny), and once possessed a charter of incorporation, which was forfeited in the reign of William III. It is 14 miles W. by N. of Monmouth, and 143 W. by N. of London; lat. 51° 59′ N., long. 2° 58′ W.

ABERNETHY (JOHN), a distinguished surgeon, born in the year 1763-4, either at the town of Abernethy in Scotland, or at that of Derry in Ireland, for each claims the honour of having been the place of his birth. He died at Enfield, after a protracted illness, on the 18th of April, 1831, in the sixty-seventh year of his age. In early youth he removed from the place of his birth, and resided with his parents in London. He received the elements of grammatical and classical instruction at a day-school in Lothbury, but it does not appear that he enjoyed the advantage of any higher education than that afforded by the ordinary day-school of that period. At the usual age he was apprenticed to Sir Charles Blick, surgeon to St. Bartholomew's Hospital, under whom, and especially in the wards of this hospital, he had ample opportunities of acquiring a thorough knowledge of his profession, of which he availed himself with diligence. Competent judges, who observed at this early period the qualities of his mind and his habits of study, predicted that he would one day acquire fame if not fortune. Though he appeared before the public early as an author, and though his very first works stamped him as a man of genius, endowed with a philosophical and original mind, yet he did not rise into reputation nor acquire practice with rapidity. In 1786 he succeeded Mr. Pott as assistant-surgeon to St. Bartholomew's Hospital, and shortly afterwards took the place of that gentleman as lecturer on anatomy and surgery. For a considerable time he had but few pupils, and he was at first by no means a good lecturer, his delivery being attended with a more than ordinary degree of hesitation. On the death of Sir Charles Blick, his former master, he was elected surgeon in his room; and, subsequently, St. Bartholomew's Hospital obtained under him a reputation which it had never before acquired.

Abernethy was a pupil of John Hunter, and the earnestness and delight with which, at an early age, he received the lessons of this his great master, were indications of the soundness of his own judgment. It was from this profound and original thinker, who exercised an extraordinary influence over the understanding, tastes, and pursuits of his young pupil, that Abernethy derived that ardent love of physiology, by the application of which to surgery, he was destined to convert a rude art into a beautiful science. He made himself thoroughly acquainted with anatomy, but it was that he might be admitted into the *then* new world of physiology; he studied structure, but it was that he might understand function: and the moment he had obtained a clear insight into these two sciences, he saw the applications of which they were capable to the treatment of disease. From that moment he looked with contempt on the empiricism then almost universal in surgery; he ridiculed its jargon; he exposed the narrowness of its principles, if it be at all allowable to designate by such a term the ignorant dogmas which alone regulated the practice of the surgeon. But he did not content himself with deriding what truly deserved contempt; he laid the foundation of, and mainly contributed to build up, a new edifice. By the diligent study of nature, and by continual reflection on what he saw, and, as he himself expressed it, the concatenation of what he saw, he reduced to order what he found a chaos. Hitherto the surgeon had looked upon the class of diseases which it was his part to treat, diseases which almost always have a local seat, as diseases which have also a local origin, and consequently as diseases which are to be cured by local applications. To Abernethy belongs the great merit of first perceiving, in its full extent, the utter incompatibility of this notion with the true phenomena of disease, and the inertness, or, when it ceased to be inert, the mischievousness of the treatment that grew out of it. In a work abounding with acute and original observation, and exhibiting comprehensive and philosophical views, entitled, *The Constitutional Origin and Treatment of Local Diseases*, he lays down and establishes this great principle:—that local diseases are symptoms of a disordered constitution, not primary and independent maladies; and that they are to be cured by remedies calculated to make a salutary impression on the general frame, not by topical dressing, nor any mere manipulations of surgery. This single principle changed the aspect of the entire field of surgery, and elevated it from a manual art into the rank of a science. And to this first principle he added a second, the range of which is perhaps somewhat less extensive, but the practical importance of which is scarcely inferior to that of the first—namely, that this disordered state of the constitution either originates from, or is rigorously allied with, derangements of the stomach and bowels, and that it can only be reached by remedies which first exercise a curative influence upon these organs. The benefit daily and hourly conferred upon mankind by the elucidation and establishment of these two principles, both by the prevention and the mitigation of disease and suffering, it were vain to attempt to estimate, and it is not easy to pay to their author the debt of gratitude which is his due.

Further, the same philosophical view of the structure and functions of the human frame, which enabled this acute physiologist so greatly to improve the theory and practice of surgery, suggested, and at the same time armed him with the courage to perform, two operations in surgery bolder than any that had ever before been achieved, and the repetition of which has since been attended with splendid success—namely, the tying the carotid and the external iliac arteries. The announcement of the performance of these capital operations, at once established his reputation as a surgeon, and increased the credit of the English school throughout Europe.

Great, however, as was the reputation which this distinguished man acquired as an anatomist, physiologist, and surgeon, it is probable that he owed his celebrity chiefly to his success as a teacher. Gifted with the genius to master and extend his science, he was endowed with the still rarer capacity of communicating to others in a clear, succinct, impressive, and fascinating manner, whatever he himself knew. Easy and fluent, yet not inelegant—abounding with illustration and anecdote, yet methodical—logical, yet often witty, and occasionally humorous almost to coarseness—seldom impassioned, yet always impressive, and never allowing the attention of his audience to flag for a single moment,—it was rare, indeed, that he failed to convince whoever heard him, and as rare that he failed to make whoever was convinced a decided partizan. Nevertheless, a highly competent witness, speaking apparently from a careful and mature examination of the impression made upon his own mind by the prelections of his master, gives the following account, which, if true, is decidedly unfavourable as to the ultimate result of the mode and spirit of his lecturing. 'He so eloquently expounded some of the highest truths,' says Dr. Latham; 'he so nicely disentangled the perplexities of many abstruse subjects; he made that so easy which was before so difficult,—that every man who heard him feels perhaps to this day, that for some important portion of his knowledge he is indebted to Mr. Abernethy. But he reserved all his enthusiasm for his peculiar doctrine; he so reasoned it, so acted it, and so dramatised it (those who have heard him will know what I mean); and then in his own droll way he so disparaged the more laborious searchers after truth, calling them contemptuously "the Doctors," and so disported himself with ridicule of every system but his own, that we accepted the doctrine in all its fulness. We should have been ashamed to do otherwise. We accepted it with acclamation, and voted ourselves by acclamation the profoundest of medical philosophers, at the easy rate of one half-hour's instruction. The great Lord Chatham, it is said, had such power of inspiring self-complacency into the minds of other men, that no man was ever a quarter of an hour in his company without believing that Lord Chatham was the first man in the world, and himself the second; and so it was with us poor pupils and Mr. Abernethy. We never left his lecture-room without thinking him the prince of pathologists, and ourselves only just one degree below him.'

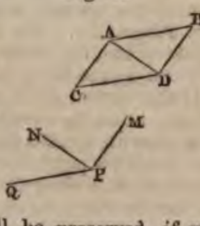
If this were, indeed, the ordinary result, then it must be admitted that the excellence of Mr. Abernethy, as a teacher, was, after all, but of a secondary order. *He* only teaches well who sends his pupil away thirsting after truth, determined to search for it, feeling that he has a clear conception of the manner in which he is to get at it, and, at all events, in no mood to be satisfied with anything but the entire truth.

The private character of Mr. Abernethy was blameless. He was highly honourable in all his transactions, and incapable of duplicity, meanness, artifice, or servility. His manners in the domestic circle were gentle, and even playful; he gave to those about him a large portion of what his heart really abounded with—tenderness and affection; and on his part he was tenderly beloved by his children and by all the members of his family. In public, and more especially to his patients, his manners were coarse, capricious, churlish, and sometimes even brutal. It would not be difficult to account for this anomaly were there any use in pursuing the investigation: his conduct in this respect merits unqualified censure. If but one-half of the stories that are told of him be true, the feelings they should excite are disgust and indignation. Without doubt it is the interest of every patient to state his case to his medical adviser in as few and plain words as possible, and then to listen without interruption to the counsel that is given him; but no one knew better than Mr. Abernethy how utterly ignorant even the educated classes are of the structure and functions of the animal economy, and how completely they have been excluded from the means of obtaining any information on these subjects. No one knew better than he that in the cases in which he was consulted there was often real suffering, though there might be exaggerated statement and unreasonable complaint; that suffering is not the less suffering because it is self-inflicted, and that it is bitter indeed when the very person from whom solace is sought treats it with derision and reproach. To listen to the interminable details of a bewildered and possibly a selfish hypochondriac may, indeed, be a 'trial of temper;' but the deportment of the medical practitioner, even towards such an hypochondriac who applies to him for guidance and aid, ought to be under the control of principle, rather than of feeling. Whatever be the folly of a patient, it can never forfeit his claim to humanity,—of which the physician, from the knowledge which his profession gives him of the weakness, infirmity, and suffering of human nature, ought to be more observant than any other human being.—[For a list of the various Tracts published by Mr. Abernethy, see Watt's *Bibliotheca Britannica*. A collected edition of his surgical works appeared in 1815, in 2 vols. 8vo.]

ABERRATION (of Light), an astronomical phenomenon, being an apparent alteration in the place of a star, arising from the combined motion of the spectator, and of the light which brings the impression of the star to his eye. We should, however, premise, in order that the reader may not form too large a notion of aberration, that it is never so much as 21″, that is, the apparent place of the star differs from its real place less than the *ninetieth* part of the apparent diameter of the sun. It is no wonder, therefore, that practical astronomy was considerably advanced before this discovery was made. If our sense of vision were perfect, or if light moved no faster than a rain-drop, we should have *terrestrial aberration*, that is, objects would change their relative places when we began to move, and if we went as fast as a ray of light moved, the utmost confusion would be the consequence. When we ride in a carriage, into which the rain is beating, we mistake the direction of the rain, for the cause of which phenomenon, see APPARENT MOTION. But as light moves with a velocity which imagination cannot conceive, about 200,000 miles in a second, its motion is so great compared with any we can give ourselves, that its passage from any one terrestrial object to another may be considered as instantaneous. The motion of a spectator on the earth which goes round the sun at the average rate of about eighteen miles in one second, though less than the ten thousandth part of that of light, is nevertheless sufficient to cause a small variation in the place of the star, perceptible by good astronomical instruments.

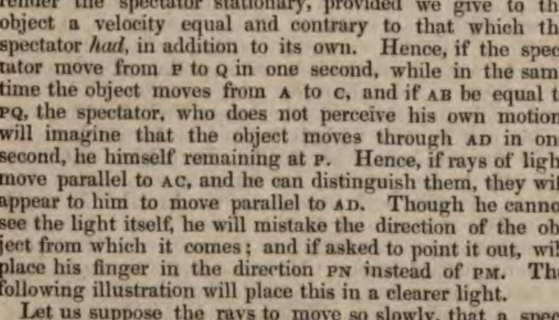
We know (see APPARENT MOTION) that if a body A be struck in two different directions at the same instant, with impulses which would separately carry it through AB and AC in one second of time, the result of the combined impulses is, that it moves in one second through AD, the diagonal of the parallelogram, whose sides are AB and AC. Again, if the spectator and the object at which he is looking are both in motion, the appearances presented by the motion will be preserved, if we render the spectator stationary, provided we give to the object a velocity equal and contrary to that which the spectator *had*, in addition to its own. Hence, if the spectator move from P to Q in one second, while in the same time the object moves from A to C, and if AB be equal to PQ, the spectator, who does not perceive his own motion, will imagine that the object moves through AD in one second, he himself remaining at P. Hence, if rays of light move parallel to AC, and he can distinguish them, they will appear to him to move parallel to AD. Though he cannot see the light itself, he will mistake the direction of the object from which it comes; and if asked to point it out, will place his finger in the direction PN instead of PM. The following illustration will place this in a clearer light.

Fig. 1.



Let us suppose the rays to move so slowly, that a spectator can be furnished with a tube long enough for light to take some perceptible time in passing from one end of it to the other. This will do for our purpose, since, though by such a supposition the aberration will be very much increased, yet the effect, and the reason of it, will be of the same kind as if light were supposed to have its real velocity. The star being at an immense distance, the rays which reach the spectator in different parts of the second may be called parallel, without sensible error. Thus, while in one second the spectator moves from A to B, he receives rays of light in the direction indicated by the dotted lines. The question now is, in what direction must he hold the tube, so as to see the star through it? If he were at rest, that direction would evidently be AC.

Fig. 2.



Let AB be the line described by the spectator in one second, during which time let a ray of light move from *a* to B, or from C to A. Join A*a*, and let A*a* be the length and direction of the tube. Divide the second into any number of equal parts, say six, and carry the tube into the various positions which it will successively occupy. Consider a ray of light as a succession of little particles moving one after another in a straight line. Then when the eye has come to P, the particle *a* will have come to *p*; when the eye is at Q, the particle will be at *q*, and so on. We have then so placed the tube, that its motion will not interfere with that of the ray, which moves as freely in the moving tube as it would do if there were no tube. To the spectator, who does not perceive his own motion, the tube is stationary, and the ray of light appears to come down it; therefore A*a* will be the direction in which he sees the star, instead of AC. The angle CA*a*, contained between the real and apparent directions, is what is called the *aberration*. Here *a*A is the diagonal of the parallelogram B*a*CA, in which *a*C is equal and opposite to AB, as before noticed. To apply this, we must remark,—

1. That the above figure is much distorted, since AB is not the ten thousandth of *a*B; whence the aberration will be very small.

2. That the aberration is in the plane passing through AB, the line of the earth's course for the moment, and through the real direction AC of the star; whence, as the earth changes the direction of its motion in going round the sun, the direction of the aberration will also change.

3. That we have committed an error in supposing the lines AC and B*a* to be parallel, since they meet at the star; which error, on account of the star's enormous distance, will be imperceptible.

4. That AB is not properly the spectator's motion round the sun only, but compounded of that and his motion round the earth's axis; the latter, however, being at most not one-third of a mile in a second, while the former is eighteen miles per second, does not produce any sensible aberration.

5. The real direction AC of the light may be considered as the same at every part of the earth's orbit, on account of the distance of the star.

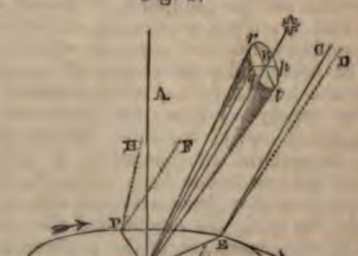
6. The aberration always throws the star apparently nearer to the earth's course, that is, A*a* is always within the angle CAB.

7. The aberration is greater or less according as the angle CAB is nearer to, or further from, a right angle, and is greatest when CAB is a right angle. This result may readily be proved by those who understand trigonometry, if they recollect that AB and *a*A are given, being the velocity of the earth and the *apparent* velocity of light, and that

$$\sin \mathrm{A}a\mathrm{B}, \text{ or } \sin \mathrm{CA}a = \frac{\mathrm{AB}}{a\mathrm{A}} \sin a\mathrm{BA} = \frac{\mathrm{AB}}{a\mathrm{A}} \sin \mathrm{CAB}.$$

Let us suppose, which will be exact enough for our purpose, that the earth moves in a circle (the ecliptic), of which the sun is in the centre. The line SA, perpendicular to the plane of the ecliptic, looks towards the *pole* of the ecliptic. Let SB be the direction of a star, PSQ perpendicular in the plane of the ecliptic to SB, and RST perpendicular to PSQ in the same plane. When the earth is at E, it is moving in the direction EM perpendicular to SE, and the star, from its great distance, is in the direction EC parallel to SB.

Fig. 3.



Hence the aberration takes place in the plane CEM, that is, the star is a little lowered towards EM, and appears in the direction ED. Let the needle SN move round the circle with the earth, so as always to indicate the direction in which the earth is moving, that is, SN is always parallel to EM, and perpendicular to SE. The plane BSN being parallel to the plane CEM, is the plane in which aberration would appear to take place if the spectator were at S, and S was moving; but as the spectator does not perceive his own motion, let us suppose him placed at S, and the same aberration to take place in the plane BSN, which really does take place in CEM. By what has been said, the aberration is greatest when the needle points to Q or P, that is, when the earth is at T or R; and least, when the needle points to T or R, that is, when the earth is at P or Q; because the angle BSN is a right angle when N is at P or Q, and differs most from a right angle when N is at T or R. Hence the aberration increases as the earth moves from P to T, diminishes from T to Q, increases from Q to R, and decreases again from R to P. The line in which the star appears, moves round SB in the course of a year, and describes a cone, while the star appears to describe a small oval or ellipse about B, the greater axis of which is parallel to PQ, and the lesser to RT; such as *prqt*, in which *p* is the apparent place when the earth is at P, and so on. This deviation is completed in the course of a year.

When the star itself is in the pole of the ecliptic, or is seen in the direction SA, the angle ASN is always a right angle, the aberration is always of the same magnitude, and the apparent path of the star is a circle. As we take stars in which SB is more inclined to the ecliptic, the oval becomes flattened in proportion to its length, so that when the star is in the ecliptic, it appears to vibrate backwards and forwards in a straight line, going and returning once in each year.

If the star be on the solsticial colure, the points P and Q will be the equinoxes, and R and M the solstices. The aberration will consequently be greatest at the solstices, and least at the equinoxes. We shall refer to this case presently.

The stars appear to us to lie on a large sphere, of which we are at the centre. [See APPARENT MOTION, SPHERE.] We may represent the phenomenon on a common globe by drawing a small ellipse or oval round the star, the major axis of which is parallel to the ecliptic, and the figure of which is more or less flattened as the star is nearer to, or further from, the ecliptic. The major axis will always be an arc of 41″, and the minor axis will be 41″ multiplied by the *sine* of BSM or the star's latitude.

Previously to entering upon the quantity of aberration, we shall give some account of the discovery, which is one of the most remarkable in the history of science. The arguments for the motion of the earth, though tolerably conclusive, were yet principally derived from the great simplicity of this hypothesis in comparison with others, since all the phenomena then observed could be equally well explained upon the supposition, that the other planets moved round the sun, at the same time that the sun moved round the earth. It remained, therefore, to find some *experimentum crucis*, some phenomenon, which admitted of no *other* explanation except what could be derived from the earth's motion. The first idea which suggested itself to astronomers was, that if the earth really moved, the stars would appear to change their places; though they did not count much upon this, since they knew that the distance of the stars might be so great, that the whole diameter of the earth's orbit would be too small a change of position to cause any perceptible change of place. [See PARALLAX.] To illustrate this, suppose that when the earth is at Q, we look at the star in the direction QG, and when it is at P, in the direction PF. Draw PH parallel to QG. The spectator, who imagines himself at rest, will, if he observes the star at these two epochs, see a difference of position corresponding to the angle HPF, at least if the distance of the star be not so great as to render that angle imperceptible to his instruments. This, however, will take place in the plane passing through the star and PQ, whereas the effect of aberration takes place in a plane perpendicular to that plane. Picard, Hook, and Flamsteed had all observed slight changes in the position of the stars; but seeing that they were in a direction different from that which would have been caused by the earth's motion only, they do not appear to have advanced any other explanation. In 1725, Bradley, Savilian Professor of Astronomy at Oxford, and afterwards Astronomer Royal, and Molyneux, the son of Locke's well-known friend of that name, set about this question conjointly. The most correct instrument for measuring very small angles was, at that time, the zenith sector [see ZENITH SECTOR], and a very large one, having a telescope twenty-four feet long, made by Graham, one of the most celebrated artists this country has produced, was erected at Kew, under the directions of Molyneux. A zenith sector measures the angular distance from the zenith, at which a star passes the meridian, the zenith being determined by a plumb line. The instrument having a very small range, the star must not be far from the zenith, and the one chosen on this occasion was γ Draconis, which happens to be within about 16° of the pole of the ecliptic, and passes very near the zenith of London. This star will, from the preceding account of aberration, appear to describe nearly a small circle about the place it would have if the earth had no motion, which is called its *mean place*. In the maps of the stars, published by the Society, the little circle, which represents γ Draconis, will do well enough to give an idea of the path which it describes every year. By measuring the star's zenith distance when on the meridian, its *polar* distance was also measured, since the zenith and pole are both points of the meridian, distant from one another by the *colatitude* of the place. [See COMPLEMENT.] That is, by adding the difference between 90° and the latitude of Kew to the meridional zenith distance of the star at that place, we obtain its polar distance. In *fig*. 4, S represents the mean place of the star, and *vsaw* the small ellipse, nearly a circle, described by the star in one year. The reader must imagine this circle placed in the heavens, and the line PS bent over his head, so that Z is his zenith and P the pole. We must now show how to find the points of the ellipse *vsaw*, answering to the four principal periods of the year—namely, the solstices and equinoxes. Referring back to *fig*. 3, in which we finally placed the spectator at S, the sun will appear to describe the circle which the earth really describes; that is, as the earth moves from Q to R, the sun will appear to move from P to T. Hence, when the earth is at Q, the aberration, throwing the apparent place of the star towards SR, 90° *before* the earth, throws it also towards a line 90° *behind* the sun's *apparent* place. Let E, *fig*. 5, be the earth, WVSA the apparent course of the sun or the ecliptic, EP the axis of the earth, AMVN the equator; whence, if the sun move in the direction indicated by the arrows, V is the vernal equinox, S the summer solstice, A the autumnal equinox, and W the winter solstice. The circle which bounds the whole figure is the *solsticial colure*, and as the star γ Draconis is very nearly on that colure, we will suppose it to be at S. Let Z be the spectator's zenith, that is, let him be on such a part of the earth that the plumb line falls in the direction ZE, the point Z will, by the motion of the earth, be carried round the dotted circle. The meridian is the moving circle passing through P and Z, and as the figure stands, the real star and the pole of the ecliptic are on the meridian. First, let the time be the vernal equinox, or let the sun appear at V; then the point W being 90° behind V, the star will appear to be thrown towards W, and its apparent place is *v*. Similarly, *s*, *a*, and *w* are the apparent places corresponding to S, A, and W, the dotted part of the ellipse being supposed to be bent over on the other side of the sphere. *Fig*. 4 is taken from *fig*. 5, and is the course of the star, as it will appear to the spectator at E, SQP being bent, so that Z is over his head, and P behind him. Let us now suppose him in the situation of Bradley, with an instrument capable only of measuring changes in the polar distance, the time being the winter solstice. As the star appears to move from *w* to *v*, which takes place between this and the vernal equinox, the polar distance will increase from day to day; after the vernal equinox it will decrease, and continue to do so until the autumnal equinox; after which, it will increase again till the winter solstice. This is precisely the phenomenon observed by Bradley, who at first suspected that it arose from some irregularity in the instrument, or deviation of the plumb line, and afterwards from some *nutation*, or conical motion of the earth's axis. These, however, he found would not account for the phenomenon. After setting up another instrument, and trying several other stars, it struck him, by what steps he has not told us, that the motion of light,

Fig. 4.

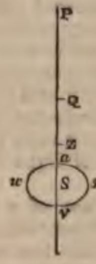


Fig. 5.

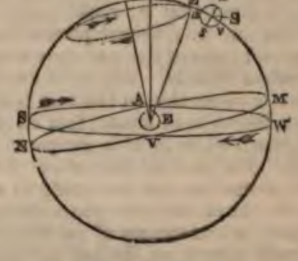
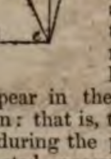


which had been previously discovered by observation of Jupiter's satellites, must, when combined with that of the earth, produce some variation in the apparent place of a star. Following up this idea, he found that it was fully sufficient to account for the deviation he had observed. We have previously explained why the idea of a parallax or change of place in a star, arising from the earth's change of place, did not withdraw his attention for a moment, though the hope of proving the sensible existence of such an irregularity was the primary motive of his observations.

The greatest aberration, as we have observed, is parallel to the ecliptic, and is the greatest semidiameter of the apparent annual ellipse of a star. This ought to be the same for all stars, if the rays which come from them move with the same velocity. Hitherto it has not been discovered that the greatest aberrations of different stars differ by more than may reasonably be imputed to instrumental errors; we must therefore conclude that, as far as we know, the light of every star moves with the same velocity. Bradley made the greatest aberration $20''$; others have deduced different values, varying from $20\frac{1}{4}''$ to $20\frac{7}{10}''$; but the result which appears most entitled to confidence, is that deduced by Mr. Richardson, Assistant Observer at the Royal Observatory, Greenwich, from more than four thousand observations, for which he received the gold medal of the Astronomical Society. He makes the aberration to be extremely near to $20\frac{1}{2}''$; which result is the more entitled to confidence, as it does not differ more than one-tenth of a second from the mean of all the results previously obtained.

It is well known that solar light is composed of several colours, which admit of separation from one another. The light of the stars is also compounded of several colours; for though different tinges predominate in different stars, no one gives a perfectly pure colour. The phenomenon of aberration proves that these different lights move with the same velocity; for two lights, moving with different velocities from the same star, would give different quantities of aberration; that is, would make differently coloured images of the star in different places, that image being nearest to the real place of the star, the colour of which moves with the greatest velocity. But as no indication of such an appearance is observable in the very best telescopes, we are, therefore, bound to conclude, that all the different coloured light of which white light is composed, moves with the same velocity. For the determination of the velocity of light from the aberration, see the article LIGHT.

We have hitherto considered only the case of a star which has no motion of its own; let us now take that of a planet, comet, or the moon, which moves while the earth moves. Let the planet move from A to *a*, and the earth from E to *e*, in the time which it takes the light to move from the planet to the earth. Then, by what has been said, the earth at *e* receives the ray A*e*, which is imagined to be in the direction B*e*; and if the planet had remained fixed at A, A*e*B would have been the aberration, or the angle contained between its true and its apparent direction. But in the meanwhile the planet has moved to *a*, and if light were transmitted instantaneously, would appear in the direction *ea*. Hence *ae*B is the aberration: that is, to the former angle, the planet's motion round *e*, during the passage of the light, must be added or subtracted, according as the earth and planet move in the contrary or same directions. The greatest aberration of Mercury is nearly one minute; that of the moon only two-thirds of a second. To the sun, which has no motion of its own, the rule for a star in the ecliptic may be applied; recollecting, however, that as a line drawn from the sun to the earth is always at right angles, or very nearly so, to the direction of the earth's motion, the aberration is always at its greatest value, or nearly so, and is nearly $20\frac{1}{2}''$.



In the preceding account we have omitted two circumstances, which would only have perplexed the reader: firstly, every star changes its place on account of the precession of the equinoxes. [See PRECESSION.] This was known to Bradley, who was, therefore, obliged to allow for this change, before he could pretend to assign that arising from any other phenomenon; secondly, the motion of the earth not being perfectly circular, but slightly elliptical, the quantity of aberration must be a little modified on that account. The effect of this will be seen in the article REDUCTION.

ABERRATION, in Optics. The most perfect mirror, or lens, which could be made, would be one in which all the rays which come from one point should be reflected or refracted to another point. Owing to the practical difficulties in the way of forming such a mirror or lens, the spherical form is adopted, of which it can only be said, that instead of returning to a point all the rays coming from a point, it condenses so many of them near a particular point, that an apparent image is formed at that point. The point near which most rays are collected is called the focus, and the distance at which a ray cuts any line passing through the focus is called its aberration with respect to that line. For a discussion of this subject, see LENS. Again, when light is refracted through any transparent medium, its different colours have different foci; for the cause and phenomena of which see ACHROMATIC. The aberrations arising from these two causes are generally known by the names of *spherical aberration* and *chromatic aberration*.

ABERYSTWITH, a town on the coast of Cardiganshire, in South Wales, near the outlet of the joint streams of the Ystwith and Rheidiol, over the latter of which rivers, above their junction, is a neat stone bridge. It was formerly defended by walls and by a castle, but these are now in ruins. The streets are narrow and ill paved, and the houses covered with the black slate of the country. It is a busy place; and in addition to its commerce, and its fisheries of cod, whiting, herring, and mackarel, some woollen manufactures are carried on, and small vessels built. Its exports are woollen goods, calamine, lead ore, and pig lead; its imports, coal, iron, and the articles of ordinary consumption. It has also become of late a place of resort for sea-bathing. The harbour is inconsiderable, and a bar keeps out vessels of much size. The vessels belonging to the port amounted, in 1829, (according to a Parliamentary Return) to 120, with a tonnage of 6423. Charles I. established a mint here for coining silver, chiefly for the payment of the neighbouring miners· the money was stamped on both sides with the feathers, to show that it was coined in Wales. It has a national school. Population, in 1831, 4128. Aberystwith, in conjunction with Cardigan, Lampeter, and Adpar, returns one member to Parliament. Aberystwith is 39 miles N. E. of Cardigan, and 208 W.N.W. of London. Lat. 52° 24′ N., long. 4° 5′ W.

ABETTOR. The etymology of this word is somewhat uncertain; it may be derived from the Saxon *betan*, to push forward, or incite. An abettor is an instigator or setter on—one that procures another to commit a crime. If an abettor, or, as he is then usually termed, aider and abettor, be present at the time of committing the crime, he is treated as a principal; if absent, he becomes an accessary before the fact. [See ACCESSARIES.] It is to be observed, that the presence spoken of is not necessarily an actual presence within sight or hearing of the fact, for there are circumstances of connexion with the principal actor which the law will construe into a presence, although, in fact, the party may have been absent, as in the case where one man commits a robbery or murder, while another keeps watch or guard at some convenient distance. Here the keeping watch is such a direct assistance in the commission of the crime as will amount to a *constructive* presence.

Aiders and abettors are distinguished from the absolute perpetrators of a crime by being denominated principals in the second degree, whilst the latter are called principals in the first degree. Formerly, the punishment of principals in the two degrees was, in most cases, different; but now, by the statute 7 and 8 George IV., cap. 29, principals in the first and second degrees, and accessaries before the fact, are all made liable to the same punishment.

ABEYANCE is a legal term derived from the French *bayer*, to expect. It is used with reference to a freehold or an inheritance; and the expression that the freehold or inheritance is in abeyance, imports that such freehold or inheritance is not vested in any one, but is in expectation and suspense, ready to descend upon, and vest in the parties (if any such there be), who shall first fill the character required by the particular quality of the estate. This suspense of the freehold or inheritance, especially of the former, is so repugnant to the general principles of the laws which regulate the tenure of land in England, that it is not allowed except where it is unavoidable. By the old law of this country, it was always necessary that some person should be in existence, as the representative of the fee or freehold for the discharge of the feudal duties, and to answer the actions which might be brought for the fief; and by this means the maxim arose that the freehold of lands could never be in abeyance. Still it was always admitted that both the inheritance and the freehold might, in some cases, be in abeyance. Thus, in the case of glebe lands belonging to parsons, and of lands held by bishops and other corporations sole, the *inheritance* is and must always be in abeyance, as no one can, under any circumstances, be entitled to more than an estate for life in these lands; and during a vacancy of the church, the freehold is in abeyance; for, no parson being actually appointed, it cannot possibly reside in any one, nor can the freehold be in the patron, who, though he possesses a right to present to the benefice, has no direct interest in the land annexed to it.

In this case, the law acknowledges a necessity that the freehold or inheritance should for a time be in suspense or in abeyance, but such an abeyance is always discouraged as much as possible, and is never permitted by the law to be *created* by the voluntary acts of parties. Therefore if a man grant land in such a manner that the *freehold* would, if the deed were allowed to operate, be in abeyance, the law comes forward and declares the deed granting such an estate to be void; and if the grant be so framed that the *inheritance* would be in abeyance, the law declares that the inheritance shall remain in the person making the conveyance. The object of this rule of law is to prevent the possibility of the freehold subsisting for a time without an owner, an evil which it guards against with the greatest vigilance; and therefore, if, as in the case last put, land is so granted that by possibility upon the death of one person there may be no one otherwise entitled to take immediate possession, the law appoints the grantor to supply the gap, if any should occur; and though he had, as he considered and intended, parted with all his interest, another rule of law, which will be more fully considered in treating of *contingent remainders*, then steps in and gives him the land for ever. Titles of Honour are also sometimes said to be in abeyance, as where the persons next in inheritance, to the last possessor, are several females, or co-parceners. In this case the title is not extinct but is in abeyance; and may be revived at any time at the nomination of the king, who by his prerogative is said to be the fountain of honours and dignities. Several instances of the exercise of this prerogative are on record both in ancient and modern times. [See 'Coke upon Littleton' 165, *a* notes 16, 17.]

ABIB, the first month of the Hebrew year, now more generally known by the Chaldee name Nisan. This month is first mentioned by name in Exodus xiii. 4. 'This day came ye out in the month of Abib;' and in the second verse of the preceding chapter it is appointed to be the beginning of the year.

On the 14th of this month, in the evening, the great festival of the Passover commences, according to the precept in Exodus xii. 18. 'In the first month, on the fourteenth day of the month, at even, ye shall eat unleavened bread,' &c. At sunset the paschal lamb is killed, the use of unleavened bread begins, and all servile labour ceases. A sheaf of barley was gathered on the evening of the 15th, and offered up on the 16th as the first fruits of the harvest. The reaping commences the next day. The eating of unleavened bread finishes on the 21st.

In the calendar of the modern Jews, Abib is no longer the beginning of the year, its place being usurped by Tisri, which was anciently the seventh month. Abib contains thirty days, and must not begin on Monday, Wednesday, or Friday. In those cases where the beginning would fall regularly on one of those days, the occurrence is obviated by adding or taking away a day of the preceding year.

The fast of the death of Joshua is celebrated on the 26th day of the month, unless it should happen to be Sabbath, when the fast is postponed to the day following, or Sunday.

This month begins on the first appearance of the new moon nearest the vernal equinox, or the 21st of March. In 1833 the first of Abib will be on the 21st of March, on which day the new moon falls.

The word Abib signifies 'an ear of corn;' and the month, without doubt, received its name from the season in which it occurred, as the corn was then in ear in Egypt and Palestine.

Abib is the name given by the modern Coptic Christians to their month which begins on the 25th of June. The Coptic name is Epip.

ABIES, in Botany (the Fir), a genus of trees of the coniferous tribe, well-known for the valuable timber that is produced by many of the species. It was formerly considered a part of the genus Pinus itself; but modern botanists have followed the popular practice, and have distinguished it. The origin of the Latin name is unknown: that of the English appellation is the Saxon *furh-wudu*, fir-wood.

GENERIC CHARACTER.

Flowers monœcious.*

MALES. *Catkins* simple, solitary, terminal, or axillary. *Stamens* obtuse, and often callous at the apex, terminated by a jagged membrane.

FEMALES. *Catkins* somewhat cylindrical; their *scales* two-flowered, imbricated, and having frequently at their base externally a *bractea*, which is either very short or lengthened beyond the scales themselves, and terminated by a taper point.

CONES more or less cylindrical; the *scales* imbricated and woody, but not thickened at the extremity; *seeds* ending in a membranous wing.

Embryo about the length of the seed, with several closely-packed cotyledons.

Trees of various sizes, usually with a straight, conical, undivided trunk, from which proceed spreading, horizontal, or drooping branches, arranged in a pyramidal manner. *Leaves* either solitary, or collected in little fascicles, deciduous or evergreen.

From Pinus, or the pine-tree, the fir is obviously distinguished by its more pyramidal form, and by its leaves arising singly from around the stem, not by twos, or threes, or a greater number, from out of a membranous shrivelling sheath, as well as by the characters in the fructification above described. Its species form four very natural tribes, of the first of which, the silver fir may be taken as the representative; of the second, the Norway spruce; of the third, the larch; and of the fourth, the cedar of Lebanon. As most of these are interesting either for the excellence of their wood or as objects of ornament, we shall briefly notice all that are at present known. Those who wish for further information should consult *Mr. Lambert's Monograph of the Genus Pinus—L. C. Richard's Mémoire sur les Conifères—Michaux's Histoire des Arbres Forestiers de l'Amérique Septentrionale, &c.*

SECT. I. Leaves growing singly round the branches, and all turned towards one side.—SILVERS.

No. 1. *Abies Picea*, the Silver Fir (Abies pectinata, *De Candolle Fl. Franç.*, ii. 275; Pinus Picea, *Linnæus Sp. pl.* 1420; *Lambert*, t. 40). Leaves arranged like the teeth of a comb somewhat emarginate, of a whitish colour underneath. Cones erect, with very blunt closely-pressed scales, which

[Silver Fir.]

---

* In the article ABIES, and in subsequent articles of a similar description, it will be necessary to use some technical words which may present a difficulty to the reader who is unacquainted with the terms of Botany. As few of such words as possible will be employed; and a complete Glossary of them will be given under the article BOTANY.

are much shorter than the taper-pointed inflexed bracteæ. A native of the mountains of the middle and south of Europe, in stony, dry, exposed situations. Its favourite district seems to be on the Pollino and in the forest of Rubia, in the kingdom of Naples, where it is found in all its grandeur, often growing from 130 to 150 feet in height, and richly meriting the name *pulcherrima* (most beautiful), applied to it by Virgil. This tree is readily known by its leaves having their points all turned towards the sky, and being mealy underneath, as well as by its long, erect, stalkless cones, of a greenish-purple colour, bristling with reflexed taper points of the bracteæ that subtend the scales. It is the *sapin* of the French. Planks of indifferent quality, on account of their softness, are sawn from its trunk, which also yields Burgundy pitch and Strasburgh turpentine. For its successful cultivation in this country it requires strong land, such as will suit the oak, and a sheltered situation; it will then become a very large tree. From a communication to Mr. Lambert, it appears that trees have been felled which, at 100 years of age, contained six loads, or 240 cubic feet, of timber. It is said by some to grow slowly for the first fifteen years, but afterwards with great rapidity. A plant in Woburn Park is recorded to have grown for 110 years at the rate of one foot in height and nearly three and a half cubic feet per annum. Its trunk sometimes arrives at 150 feet in height, and six feet in diameter.

Antiquarians, not considering that this plant is the real *abies pulcherrima* of Virgil, and of the Roman authors, have lost themselves in vain attempts to reconcile the declaration of Cæsar (v. 12), that he found in Britain all the trees of Gaul, except the beech and abies, with the well-known fact that fir-wood is abundant in our ancient mosses, and has been met with even beneath the foundations of Roman roads. What Cæsar meant was, no doubt, that he did not meet with the silver fir in Britain; of the pine he says nothing, and therefore it is to be presumed that he found it.

No. 2. *Abies Sibirica*, the Siberian Silver Fir (Pinus Sibirica *and* Pinus Pichta *of the gardens*). Scarcely anything certain has been published of this tree, which, according to Linnæus, Mr. Lambert, and others, is the same as the Abies picea, our No. 1, but which Russian botanists distinguish as a particular species. Gmelin describes it as a native of all parts of Siberia as far as 58° N. lat. in mountainous regions, especially in the upper country lying between the Irtisch and the Ob, where it forms dense woods. The Russians call it *pichta*, or *fir*.

No. 3. *Abies grandis*, Great Californian Fir (Pinus grandis, *Douglas* and *Lambert*). Leaves long, narrow, very blunt, whitish beneath, all turned one way. Cones oblong, erect, rather curved, with very broad, uneven, downy scales, which are longer than the bracteæ.—Found, by Mr. Douglas, in low, moist valleys in northern California, where it attains the height of 200 feet. The wood is soft, white, and of inferior quality. Cones from three to four inches long; bracteæ very short, jagged, two-lobed, with a short intermediate point.

No. 4. *Abies Balsamea*, the Balm of Gilead Fir (Abies Balsamifera, *Michaux*, *Hist.*, vol. i. p. 145, tab. 14; Pinus Balsamea, *Lambert*, t. 41). Leaves flat, silvery-white beneath, either emarginate or entire at the point, all curved towards the upper side. Cones cylindrical, oblong, erect, purple, with rounded, even, undivided scales.—Found, along with *Abies nigra* and *alba*, in the coldest parts of North America, but always in detached individuals, never in large masses. It extends also along the ridge of the Alleghanies as far as the crests of the mountains of North Carolina. It forms a small slender tree, rarely more than forty feet high, with a diameter of from twelve to fifteen inches. The cones are four or five inches long, and about an inch in diameter. Its wood is light, of a pale yellow colour, and but slightly resinous; it is of little value, and is chiefly split up into staves for fish-barrels, for which, however, it is less fit than the Weymouth pine and the red variety of the black spruce fir. The English name has been given in consequence of a resemblance between the clear, transparent greenish-yellow turpentine, which is obtained from numerous cysts in its bark, and the Balm of Gilead of the shops; it is commonly known under the name of *Canadian balsam*. In England this is a small tree of very ornamental appearance, when young, on the skirts of plantations, but it rarely acquires any considerable size. The finest plants are said to be at Longleat, the seat of the Marquess of Bath.

No. 5. *Abies nobilis*, Large-bracted Fir (Pinus nobilis, *Douglas* and *Lambert*). Leaves very numerous, falcate, all turned one way, of nearly the same colour on both sides. Cones oblong, erect, with rounded broad scales concealed by the long wedge-shaped two-lobed jagged scales, which are bent back, and terminate abruptly in a rigid elongated point. A majestic tree, forming vast forests upon the mountains of northern California, where it was found by Mr. Douglas. The timber is said to be of excellent quality. The cones are about six inches long.

No. 6. *Abies Frazeri*, the Double Balsam Fir (Pinus Frazeri, *Pursh*, *Flor. Amer. Sept.*, 2639; *Lamb.*, vol. i., t. 42). 'Leaves linear, emarginate, silvery-white beneath. Cones oblong, squarrose. Bracteæ somewhat leafy, inversely cordate, mucronate, reflexed.' *Lambert.*—A native of the mountains of Carolina and Pennsylvania. Pursh is the only botanist who appears to have seen this species in its native situations. According to Mr. Lambert it is little more than a shrub, seldom exceeding ten feet, and more frequently, at least in this country, much under that height. That botanist considers it well suited for lawns and pleasure-grounds in situations where it is wanted to break particular lines, but not to interrupt the view. A fine specimen exists in the nursery of Mr. Lee, at Hammersmith.

No. 7. *Abies Webbiana*, Webb's Fir (Pinus Webbiana, *Wallich. Cat.*; *Lambert*, t. 44; Pinus spectabilis, *Lambert*). Leaves linear, solitary, flat, all-spreading, and turned one way, silvery-white beneath, with a deep notch at the extremity. Cones oblong, erect, obtuse, with very broad, rounded, even scales. According to the account of Captain Webb, who first discovered it, this remarkable species attains the height of eighty or ninety feet, with a diameter near the ground of three or four feet. Its wood seems to be valuable; in India it is used by plane-makers. From what has been reported of its general appearance, it is probably one of the most interesting species that has yet been discovered. Inhabiting the colder regions of northern India, and found among a flora that is more Siberian in its character than Indian, there can be no reasonable doubt of its being well able to withstand the rigor of the winters of this country. Plants that have been obtained for our gardens, within the last few years, have an air of health and robust strength that promises most favourably for its introduction as a common forest-tree. They are, however, like the Norway spruce, and many others, not adapted to bear frost after they have once begun to grow. High and dry stations, where the late frosts of spring are little felt, would, it is to be presumed, be the most eligible for experiments upon its naturalization. The natives call it *oumur*, and extract an indigo or purple pigment from the cones, which are represented in Indian drawings as strikingly beautiful.

No. 8. *Abies Canadensis*, the Hemlock Spruce Fir (*Michaux*, *Histoire*, vol. i., p. 137, t. 13; Pinus Canadensis, *Lambert*, t. 45). Leaves flat, arranged irregularly in two rows; when young, downy as well as the young slender branches. Cones very small, ovate, sharp pointed, with rather acute, even, entire scales: seeds very small.—The most northerly situation in which this tree is found is about Hudson's Bay, in lat. 51°. Near Quebec it forms extensive forests; in Nova Scotia, New Brunswick, Vermont, and the upper part of New Hampshire, it is extremely common; but in the middle and southern states it is confined to the Alleghanies and their dependent ridges, where it inhabits the sides of torrents and the bleakest situations. It is a noble species, rising to the height .of seventy or eighty feet, and measuring from two to three feet in diameter. It appears to be of slow growth, not arriving at its full dimensions in less than 200 years. When from twenty-five to thirty feet high its form is exceedingly elegant, but when old its huge limbs are apt to be rent and broken by winds and snow; and their naked stumps sticking out beyond the young and verdant foliage, give the trees an air of decrepitude and decay. The wood is of little value, being neither sound nor durable: it is chiefly employed for the manufacture of laths and for coarse in-door work. The bark is exceedingly valuable for tanning; mixed with oak-bark, it is said to be much better than oak-bark alone. It bears clipping well, and is therefore adapted, like the yew, to the construction of live-fences. A great deal of the essence of spruce is extracted from its shoots.

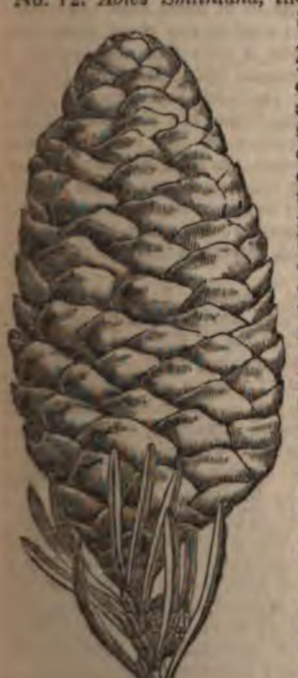
No. 9. *Abies Brunoniana*, the Deciduous Silver Fir (Pinus Brunoniana, *Wallich. Plant. As. rarior.* vol. iii. p. 24, tab. 247; P. dumosa, *Lambert*, t. 46). Leaves flat, all turned one

way, serrulate towards the points, covered beneath with a milk-white bloom. Cones terminal, erect, ovate, blunt, very small, with lax, ovate, very blunt scales.—Found in the northern parts of India in the provinces of Nepal, Butan, and Gossain Than, where it is known by the names *tangshing* and *changathasi-dhup*. A tree seventy or eighty feet high, with a clear trunk of from fifteen to twenty feet, and a spreading, very branchy head. Leaves about an inch long, falling off at a very early period, and so exceedingly deciduous, that the slightest shake of the branch is sufficient to detach them; very bright green, and shining. Cone not above an inch long, pale brown, nearly smooth, with several minute scales at its base; the scales ovate and very obtuse, subtended by a short kidney-shaped bractea. Seeds very small. The wood is of bad quality, being liable to warp, on which account it is not employed.

No. 10. *Abies religiosa*, the Sacred Mexican Fir (*Schlecthend. in Linnæa*, v. 77; Pinus religiosa, *Humboldt* and *Kunth*, *Nov. gen. et sp. pl.* vol. ii. p. 5; *Lambert*, t. 43). Young branches quite smooth. Leaves arranged in two rows, sharp pointed, covered beneath with a glaucous bloom.—Found by Humboldt on the lower hills of Mexico, between Masatla and Chilpantzingo, at an elevation of 4000 feet. Deppe and Schiede found it upon the cold mountains of Orizaba, at the highest limit of arborescent vegetation. It is described as a lofty tree, resembling Abies picea and balsamea, from which it is distinguished by its sharp-pointed leaves. The flowers are unknown. The branches are used for adorning the churches in Mexico. According to Mr. Lambert, the cones are like those of the cedar of Lebanon, but smaller, and almost black. The Mexicans call it *oyamel*. From specimens brought by Mr. Graham from Mexico, we should suppose this to be a very beautiful tree; the leaves are longer, and the branches more slender than those of any other of the Silver tribe.

No. 11. *Abies hirtella*, the Hairy Fir (Pinus hirtella, *Humboldt* and *Kunth*, *Nov. gen. et sp.* pl. ii. p. 5). Young branches covered with hairs. Leaves arranged in two rows, flat, acute, covered with glaucous bloom beneath.—Known only from the incomplete account of Humboldt, who found it on the mountains of Mexico near El Guarda, between Guchilaque and the city of Mexico, growing at an elevation of between 8000 and 9000 feet. He describes it as a small tree, three or four times as high as a man. Its cones and flowers are wholly unknown. The leaves are about an inch and a quarter long.

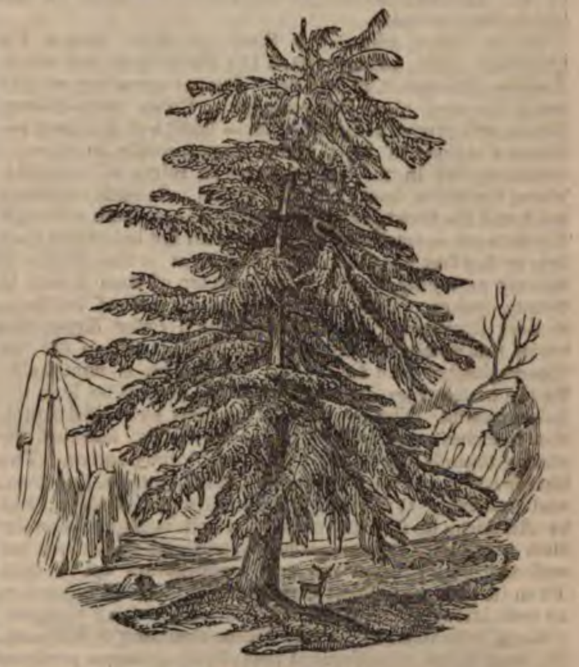
No. 12. *Abies Smithiana*, the Indian Silver Fir (Pinus Smithiana, *Wallich. Plant. As. rarior.*, vol. iii. p. 24, t. 246). Leaves slender, four-cornered, whitish beneath, a little turned towards one side. Cones erect, ovate-oblong, with obovate, rounded, even scales.—A native of the mountains next the Himalayeh, where it is called by the natives *raga*. A tree of enormous size, with nearly opposite branches, covered with short down, and so arranged as to form generally two rows. Leaves dark green, from an inch to an inch and a half in length. Cones from four to six inches long, brown, very even, and covered with a glaucous bloom. Seeds small. Nothing more is known of this plant, which is only described in Dr. Wallich's work above quoted.



[Cone of the Indian Silver Fir.]

SECT. II. Leaves growing singly round the branches, and all spreading equally.—SPRUCES.

No. 1. *Abies excelsa*, the Norway Spruce Fir (*DeCand. Fl. Franç.*, 3.275; Pinus abies, *Linn. sp. pl.* 1421). Leaves scattered, somewhat four-cornered, mucronate. Cones cylindrical, pendulous, with blunt, wavy, slightly-toothed scales.—Native of the mountainous parts of the north of Europe, where it sometimes constitutes, as in Norway, the principal timber. It is found all over Siberia as high as 70° N. lat.; in that region it is considered by the wandering tribes a certain sign of the presence of springs of fresh water, for it is only seen in moist and springy places; a property transferred to Abies picea by the late Sir James Smith, who has most strangely misapplied the statement of the Russian botanist Gmelin. When growing singly in rich soil, separate from other trees, this forms one of the most beautiful objects that can be imagined, with its long, drooping branches touching the very ground, and its regularly pyramidal figure; but in other situations, in plantations where the trees are crowded and deprived of their lower branches by want of light and air, it becomes, after nine or ten years, an inelegant plant of little value except to be cut for poles. When in perfection, and occasionally it arrives at its greatest perfection in this country, it acquires a stature of 150 feet; its wood is of a white colour, of a fine even grain, and very durable: in the market it is known under the name of white or Christiania deal. In Norway it arrives at maturity in seventy or eighty years. Trees of such an age are what are usually cut down for exportation, and each yields on an average three pieces of timber, eleven or twelve feet long. The spruce is readily known by its leaves of one uniform dull green colour, spread equally round the branches, and by its long pendant cones.



[Norway Spruce Fir.]

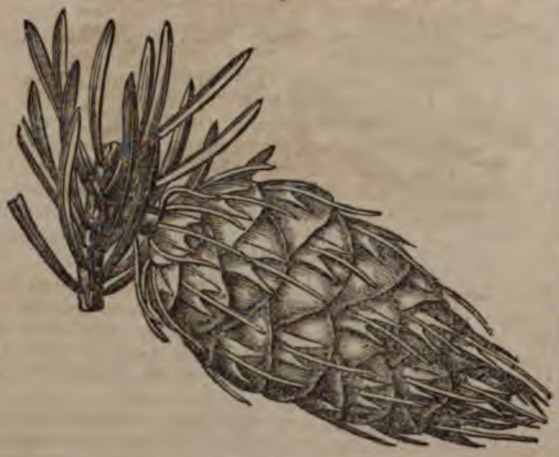
No. 2. *Abies orientalis*, the Oriental Fir (Pinus orientalis, *Linn. sp. pl.* 1421; *Lambert*, t. 39). Leaves very short, uniformly imbricated, quadrangular, with a callous point. Cones ovate, cylindrical, pendulous, their scales somewhat rhomboid. To botanists this is known chiefly by a figure published by Mr. Lambert after a drawing by Aubriet, the celebrated draughtsman, who accompanied Tournefort in his journey to the Levant. It was found by that traveller in the mountains south-east of Trebisond, above the convent of St. John. It has been subsequently met with by Russian botanists in the woods of Mingrelia, and near Teflis by Sir Gore Ouseley; but little has been added to our knowledge of the species. The young branches are said to be hairy. The leaves are very short and dense. The cones are small and pendulous, of an ovate, tapering figure.

No. 3. *Abies alba*, the White Spruce Fir (*Michaux, Hist.*, vol. i. p. 136, t. 12; Pinus alba, *Lambert*, t. 36). Leaves rather glaucous, spreading equally round the branches, four-cornered, somewhat pungent. Cones narrow, oval, tapering towards the point, with even, undivided scales. Found along with *Abies nigra* in the colder regions of North America; according to Michaux it does not advance so far to the northward as that species, from which it is known not only by its smaller size, the trunks rarely exceeding forty or fifty feet in height, but also by the bluish cast which characterizes the foliage, and which gives it a much lighter appearance than the sombre *abies nigra* Dr. Richardson, however, states that it was the most northerly tree observed in Franklin's Polar journey. The timber is of inferior quality. From the fibres of the root, macerated in water, the Canadians prepare the thread with which they sew together the birch-bark that forms their canoes. Its resin is also used to render the seams water-tight. Mr. Lambert appears to have been misinformed as to the essence of spruce being prepared from the branches of this species, which appears on the contrary from the statements of Michaux to be carefully rejected, because its leaves are thought to impart an unpleasant flavour. The bark is said to be occasionally used for tanning. Milton Abbey in Dorsetshire, and the grounds of the Earl of Tankerville at Walton, are named by Mr. Lambert as stations where fine specimens of this species may be seen.

No. 4. *Abies nigra*, the Black, or Red, Spruce Fir (*Michaux, Hist.*, vol. i. p. 125, t. 11; Pinus nigra *and* rubra, *Lambert Monogr.*, t. 37 and 38). Leaves spreading equally round the stem, short, four-cornered. Cones ovate-oblong, obtuse with ragged rounded scales.—Native of the most inclement regions of North America, especially in swampy situations and in the valleys between ridges of low hills, where the soil is deep black and humid. In such situations are found the finest forests of this species, and there, although the trees are so crowded together as often not to be more than four or five feet apart, the timber arrives at the height of seventy or eighty feet, with a diameter of from fifteen to twenty inches. The firs in the landscapes of northern scenery illustrating Captain Franklin's *Polar Expedition* are of this species, which, however, Dr. Richardson did not observe higher than 65° N. lat. The trunk is remarkable for the perfect regularity with which it diminishes from the base upwards. The head is of a regularly pyramidal figure, the branches spreading almost horizontally, and not inclining towards the earth, as in the Norway spruce. The timber is of great value on account of its strength, lightness, and elasticity. It is employed for the yards of ships; and in America, in districts where the oak is scarce, also for their knees: floors are occasionally laid with it, but it is not well adapted for this usage, as the planks are apt to split. From its young branches is extracted the *essence of spruce*, so well known as a useful antiscorbutic in long voyages; and not from those of the Abies alba, according to Michaux. By some it has been thought that North America produces a red as well as a black spruce, the former being of better quality than the latter; but the researches of Michaux show that what differences exist are due exclusively to the influence of soil, and have no dependence upon specific peculiarities.

According to Mr. Lambert, the curious dwarf spruce, called *Pinus clanbrasiliana*, is probably a variety of abies nigra.

No. 5. *Abies Douglasii*, the Douglas Fir (Pinus taxifolia, *Lambert Monogr.*, No. 43; Pinus Douglasii, *Id.* t. 47 and 48). Leaves spreading equally, deep green, whitish beneath, obtuse. Cones cernuous, ovate-oblong, with rather uneven cartilaginous scales, much shorter than the bracteæ, which are three-toothed, the lateral teeth being membranous, with the intermediate ones much longer and more rigid.—According to Mr. Douglas, the discoverer of this gigantic species, it is found in immense forests in North-West America from 43° to 52° N. lat. The trunks vary from two to ten feet in diameter, and from 100 to 180 feet in height. Occasionally it arrives at still greater dimensions; there still exists, near Fort George, on the Colombia River a stump which, without the bark, and at three feet from the ground, measures forty eight feet in circumference. An evergreen tree, with an erect, taper trunk, which when old is covered with a rough, rugged bark from six to nine inches thick, abounding in a clear yellow resin, and making excellent fuel. The young branches have their bark filled with receptacles of resin, as in the balm of Gilead. The timber is heavy, firm, of as deep a colour as yew, with very few knots, and not in the least liable to warp. We have a plank now before us, which, after standing some years in a hot room, is as straight, and its grain as compact, as the first day it was planed. The growth is exceedingly rapid; we have seen a branch three inches in diameter which was not more than eight years old. The aspect of the young branches is so deep a green, that they seem as if they were more nearly of the nature of a yew than of a spruce. In the autumn their buds are very prominent and bright brown. The cones are remarkable for the long tridentate bractæ which stick out far beyond the scales themselves.



[Cone of Douglas Fir.]

A considerable number of plants of this important species are now scattered among the parks and woods of this country, some hundreds having been raised and distributed by the Horticultural Society. It appears to suit this climate perfectly, and to be likely to prove more valuable than even the larch itself, being evergreen, and fully as hardy.

No. 6. *Abies Menziesii*, the Menzies Fir (Pinus Menziesii, *Douglas, Lambert*). Leaves very short, rigid, rather sharp-pointed, whitish beneath, spreading regularly round the stem, very deciduous. Cones oblong, composed of very lax, ragged retuse, ovate, thin scales, much longer than the narrow, serrated, concealed bracteæ. Buds ovate, acute, covered with resin.—A native of Northern California, where it was found by Mr. Douglas, who describes the wood as being of excellent quality. The cones, which are about three inches long, are extremely different from those of any other species. The branches, deprived of their leaves, are covered with thin, hard, projecting bases, which give them a singularly tuberculated appearance.

SECT. III. Leaves growing in clusters; deciduous.—LARCHES.

By some botanists this section is considered essentially different from Abies; but the want of any clear, distinctive characters, either in the mode of growth or the organs of fructification, induces us to concur with Linnæus, Jussieu, and Richard, in considering the larch the same genus as the spruce. The leaves of the former are clustered or fasciculated, merely in consequence of the universal nondevelopment of lateral branches; so that the leaves themselves make their appearance without a perceptible central axis. This is proved not only in the cedar of Lebanon, but even in the larch itself, by numerous cases where the branches being less abortive than usual, lengthen enough to display their real nature.

No. 1. *Abies Larix*, the Common Larch Fir (*Rich. Monogr. Conif.* 164, t. 13; Pinus Larix, *Linn. sp. pl.* 1427, Larix Europæa, *De Cand. Fl. Franç.*, 3.277). Leaves clustered, deciduous. Cones ovate-oblong, blunt.—A native of the mountains of the middle of Europe, of Russia, and of Siberia. In the latter country it is the commonest of all trees, delighting in dry, elevated situations, where it forms vast forests, sparingly intermixed with pines. Its trunk grows very erect, with graceful drooping branches, gradually diminishing from the base to the apex, and giving it a regularly pyramidal form. In the spring, when its young leaves have just burst into life, it has a peculiar bright yellowish-green tint, which is possessed by no other tree of our forests. The larch has been now, for many years, extensively cultivated upon barren, exposed land, both in England and Scotland, and it has been found one of the most profitable of all trees to the planter, provided the land be well drained; but it will not succeed in swampy situations. It grows with great rapidity, is subject to very few accidents, transplants with but little risk, and produces timber of great excellence and value, not only for domestic but for naval purposes. In mountainous districts in Scotland the Duke of Athol has planted it in immense quantities; and it appears, from a report of that nobleman to the Horticultural Society, that in situations 1500 to 1600 feet above the level of the sea, he has felled trees, eighty years old, that have each yielded six loads of the finest timber. Three varieties are mentioned by botanical writers; of these the first is remarkable for the young cones being pale green instead of crimson; the second has a weeping habit: both these are natives of the Tyrol. The third sort is of a slow, stunted growth, and an inelegant appearance, leafing early, and very subject to injury from spring frosts; it was raised by the Duke of Athol from Archangel seeds.

[The Larch.]

From the boiled inner bark, mixed with rye-flour, and afterwards buried for a few hours in the snow, the hardy Siberian hunters prepare a sort of leaven, with which they supply the place of common leaven when the latter is destroyed, as it frequently is, by the intense cold to which hunters are exposed in the pursuit of game.

The bark of the larch is nearly as valuable to the tanner as oak-bark; it also produces the substance called Venice turpentine, which flows in abundance when the lower part of the trunk of old trees is wounded. A sort of manna, called Briançon manna, is exuded from its leaves in the form of a white flocculent substance, which finally becomes concreted into small lumps.

It is believed that this species was the *πίτυς* of the ancient Greeks. The origin of the more modern word *larix* is uncertain. By some it is derived from the Celtic *lar*, fat, in allusion to its unctuous, inflammable resin; by others from the Welsh *llär*, wide-spreading: it is, however, more likely to have been in some way connected with the word *l'aris*, which appears, from a very curious paper by Mr. Drummond Hay, read some time since to the Horticultural Society, to be the Berber name of a large coniferous tree found in Rif, or Er rif, and in all the higher sierras of Marocco.

No. 2. *Abies microcarpa*, the Red Larch Fir (Pinus microcarpa, *Lambert*, t. 50). Leaves clustered, deciduous. Cones oblong, small; their scales erect, close-pressed, the upper ones much smaller than the lower.—A graceful tree, with much of the habit of the common larch, from which its very small cones, of a bright purple in the summer, readily distinguish it.—A native of North America. This is by no means so well adapted to the planters' purposes as the common larch, growing very much smaller. According to the Duke of Athol, who cultivated this in his larch-plantations in Scotland, trees, when fifty years old, do not contain one-third as many cubic feet as the common larch. The wood is so heavy that it will scarcely swim in water.

No. 3. *Abies pendula*, the Black Larch Fir (Pinus pendula, *Lambert*, t. 49). Leaves clustered, deciduous. Cones oblong, with numerous spreading scales, which gradually diminish from the base to the apex of the cones. Branches weak and drooping.—A native of North America, where it is found growing in a rich clay soil, mixed with sand, in cold mountainous districts. When cultivated in this country it is an elegant tree, having a good deal of resemblance to the common larch, but being of a brighter green colour, and much more graceful. The leading shoot will often begin to droop at the height of fifteen or twenty feet from the ground, and, after gradually acquiring a horizontal direction, will bend towards the earth so as to form a natural arch of great beauty. The wood is less valuable than that of the common larch.

SECT. IV. Leaves growing in clusters; evergreen.—CEDARS.

No. 1. *Abies Cedrus*, the Cedar of Lebanon Fir (Pinus Cedrus, *Linnæus*, *Lambert*, t. 51). Leaves clustered, evergreen. Cones oblong, very obtuse, erect, with broad closely-packed scales, which are a little thickened at the margin.—Mount Lebanon and the range of Taurus are the native spots of this most stately and magnificent tree, which compensates for its want of height by its huge wide-spreading arms, each of which is almost a tree in itself. According to Labillardière, a French traveller in Syria, the largest of those now remaining on Lebanon is, at least, nine feet in diameter; the trees are held in great veneration, and a holiday is set apart for the *feast of cedars*. Its growth is far from being so slow as some imagine; on the contrary, the observations of those who have cultivated it with care prove that it will vie in rapidity of growth with almost any forest tree. It appears from Mr. Lysons' inquiries that there is a tree at Highclere, the seat of the Earl of Caernarvon, which, when fifty-eight years old, measured ten feet one inch in circumference at three feet from the ground. Cedar wood has the reputation of being indestructible: instances have been named of its having been taken from buildings uninjured after a lapse of two thousand years. Mr. Lambert, however, remarks, with justice, that 'in relation to these properties, there is much vulgar error and confusion, the cedar of Lebanon being often confounded with trees of different genera.' Mr. Lambert conjectures that the Cedrus of the Greeks was the wood of *Cupressus horizontalis*; Sprengel refers it to the *Juniperus oxycedrus*; but it appears highly probable, from some interesting observations made at Tangier by Mr. Drummond Hay, that the indestructible cedar wood was the beautiful, hard, deep-brown timber of Thuja articulata, the Sandarac tree (see THUJA). The wood of Abies cedrus produces deal of very indifferent quality.

[The Cedar of Lebanon.]

No. 2. *Abies Deodara*, the Sacred Indian Fir (Pinus Deodara, *Lambert*, t. 52). Leaves evergreen, in clusters, acute, triangular, stiff. Cones growing in pairs, stalked, oval, obtuse, erect; the scales closely packed, very broad, and nearly even at the margin.—A native of the mountains of India near the town of Rohilcund, on the alps of Nepal and Thibet, at a height of 10,000 or 12,000 feet, and also in the woods of Almorah. A large tree, with a trunk about four feet in diameter, resembling the cedar of Lebanon, from which it differs in having its cones upon stalks and its leaves longer and more distinctly three-sided, and also in the quality of its timber. According to Mr. Moorcroft, from whose notes, in Mr. Lambert's monograph of the genus, we borrow much of our information, the Hindoos call it the Devadara, or God tree, and hold it in a sort of veneration. Its wood is extremely durable, and so resinous that laths made of it are used for candles. Spars of it have been taken out of Indian temples, known to have been erected from 200 to 400 years, uninjured except in those parts which originally were sapwood. Mr. Moorcroft procured specimens from the starlings of the Zein ool Kuddul bridge, in Ladakh, where it had been exposed to the water for nearly 400 years. Mr. Lambert says that its wood takes an excellent polish, being very close-grained, and perhaps the most valuable of the genus. A few plants are now growing in the gardens of Great Britain, having been reared from seeds brought from India by the Hon. Mr. Melville: they are too young for us to judge of their suitableness to this climate, but there is every reason to believe that they will be as hardy as the now common cedar of Lebanon.

Two varieties, or perhaps nearly-related species, called the *Shinlik* and *Christa rooroo*, are mentioned by Moorcroft as natives of the forests of Ladakh.

To the species now enumerated, the following almost unknown kinds have to be added:—

No. 3. *Abies Kæmpferi* (Pinus Kæmpferi, *Lambert. Monogr.*, Preface, p. vii.; Pinus Larix, *Thunberg. Fl. Japon.*, p. 275). A native of Japan, found wild upon the mountains of Fako; called by the natives *Leosi*, or *Kara maats Nomi*, according to Kæmpfer.

No. 4. *Abies Thunbergii* (Pinus Thunbergii, *Lambert. Monogr.*, Preface, p. vii.; Pinus Abies, *Thunb. Fl. Japon.*, p. 275). A scarce plant in Japan, where it is found even in the city of Jeddo, according to Thunberg.

No. 5. *Abies Momi*, (Siebold in verhand. Bataav. genootsch. xii., p. 12.) Found in Japan, as well as the two following. Its wood is, according to Siebold, in great estimation on account of its whiteness and fine grain.

No. 6. *Abies Torano.* Id.

No. 7. *Abies Araragi.* Id. Wood brown; used for various domestic purposes.

The genus of resinous plants called Abies, which we have thus described, comprehend many forest trees of great importance; and it will be, therefore, proper to add a few remarks on their cultivation. Some of them, such as the larch, the Norway spruce, the silver fir, and the balm of Gilead, are raised in the nurseries annually in the open ground, in large quantities, for the supply of our plantations; others, such as the cedar of Lebanon and the Douglas fir, are procured in much less abundance, and are treated with more care, being usually kept in pots until they are finally committed to the earth in the situation they may be subsequently destined to occupy.

All the species are increased by seeds; they may also be propagated both by inarching and by cuttings; but it is found that plants so obtained are either very shortlived or stunted, unhealthy, and incapable of becoming vigorous trees. In some of the species, such as the balm of Gilead and the silver fir, the scales of the cones readily separate from their axis, so as to render the extraction of the seeds a simple and easy operation; but in others, such as the larch and the spruce, the scales will neither separate nor open. in such cases it is necessary to dry the cones as much as possible, then to split them by means of an instrument passed up their axis, and afterwards to thresh the portions so separated till the seeds can be sifted out.

Like other resinous seeds, these are perishable unless sown within a few months after the cones have been gathered; they will, however, keep much longer in the cone than if separated; wherefore, they should always be imported in that state.

It is usual in the nurseries to sow them in the spring in beds of light soil, in which no recent manure has been mixed: they are buried at various depths, according to the force of the vital energy of the species. This has been found by experience, as it is said, to be one inch for the silver fir; half an inch for the spruce, balm of Gilead, and cedar of Lebanon; a quarter of an inch for the larch; and less for the American spruce: it is, however, probable that these depths are of very little importance. In order to protect the surface of the beds from being dried while the young seeds are sprouting, it is generally overspread with a thin layer of long straw, which is removed as soon as the crop begins generally to appear. During the first season the seedlings remain undisturbed; the only attention they receive being to keep them free from weeds. In the following spring the young plants are taken up carefully, and their roots, being a little shortened, are imbedded in rows about six inches apart, where they remain for one or two years. After this they are transplanted into quarters, in rows a foot or nine inches apart, the plants being about six inches from each other. Having remained in this situation for a year, they are fit to be transferred to the plantation, or they may stand two years in the quarters, and then be taken up and replaced in a situation of the same kind, if circumstances should render such a proceeding desirable. On no account, however, should they be allowed to remain in the nursery quarters more than two years at a time without being taken out of the ground, because they are apt to form long and strong roots, which are destroyed in the process of transplantation, so that the life of many must be either materially injured or wholly sacrificed.

None of the firs should be transplanted at a height exceeding three feet, for the reason last mentioned; and the larch is the only kind that will remove advantageously even at this size. The spruce and its allied species may be removed more successfully when from a foot and a half to two feet high. To this there is no other exception than that of plants that have been constantly reared in pots, as the cedar of Lebanon; these may be safely removed at any size, if the transplantation is carefully attended to, because their roots are uninjured in the operation. It should, however, be remembered, in finally planting out large firs which have been always kept in pots, that it is absolutely necessary that their roots should be spread out among the earth as much as may be practicable without straining or breaking them; because, while in pots, they necessarily acquire a spiral direction, which they will not afterwards lose unless it is destroyed at the period of final transplantation; and, if they do not lose it, they are apt to be blown over by high winds, on account of their roots not having penetrated into the earth far enough in a horizontal direction to form the requisite stay to support the trunk and head.

Where great importance is attached to the raising the seeds of rare species of fir, it has been found a very beneficial practice to place them between two turfs placed root to root, the one upon the other, and to watch them till the seeds begin to sprout; they are then to be sown in the usual way, when every seed will usually succeed.

No trees are more impatient of pruning than these. They exude, when wounded, so large a quantity of their resinous sap as to become weakened even by a few incisions; and, if they have suffered many, they are long before they recover from the effects. So great is their symmetry, and so uniformly will their branches form under favourable circumstances, that it will rarely happen that a necessity for the use of the pruning-knife can arise. The great rule to be observed in their management is to allow them ample room for the extension of their branches; if this is attended to, their beauty is not only ensured, but the rate at which they will form their timber will be an ample recompense for the space they may occupy.

ABIES, in Fossil Botany, a name given by Adolphe Brongniart to a single incomplete specimen of a fruit resembling that of some spruce fir, but of which not even the locality is known. It is called *Abies laricioides*.

ABIETINEÆ, in Botany (*Richard. Monogr. Conif.* 145), a section of CONIFERÆ, or of the FIR TRIBE, comprehending Abies, Pinus, and the genera that have in modern days been struck off from those two. For its botanical characters see CONIFERÆ.

ABINGDON, one of the principal towns in Berkshire, and a place of great antiquity. Some have carried back its origin to the time of the Britons. It received its name of Abban dun, or Abben don, the town of the abbey, from the removal hither of a monastery previously fixed at Bagley

Wood in the neighbourhood. It was a place of considerable importance in the period of the Saxon Heptarchy; and Offa, King of Mercia, had a palace here. The abbey, which was founded in the twelfth century, flourished under the favour of successive princes; and its revenues, at the dissolution of religious houses, amounted to nearly 2000*l.* per annum. Henry I. was educated in it. The town is pleasantly situated at the junction of the Ock and the Thames, just above where the Wilts and Berks canal joins the latter. The streets are spacious, diverging from the market-place, and are well paved and lighted; the supply of water is also good. The market-house is an elegant structure of freestone, and in it is a spacious hall for transacting public business. The July and October sessions and the summer assizes are held here. Abingdon returns one member to Parliament. It has a separate jurisdiction, having obtained a charter of incorporation in the reign of Philip and Mary, A.D. 1557. There are two handsome churches, those of St. Helen and St. Nicholas; and meeting-houses for the Baptists, Independents, Quakers, and Wesleyan Methodists. There is a free grammar-school well endowed, a national and a British school, and some other foundations for the purposes of education. There are also many alms-houses, in the chief of which (Christ's Hospital) thirty-two poor women are supported. The trade of Abingdon consists of malting, hemp-dressing, and sack and sail cloth making; in the latter branch of manufacture there has been a considerable decline since the peace. The corn-market is large. Capacious wharfs and warehouses have been erected at the entry of the Wilts and Berks canal into the Thames. The population of the town was, in 1831, 5259. It is 26 miles N.W. by N. of Reading, and 56 W.N.W. of London. Lat. 51° 40′ N., long. 1° 16′ W.

ABIPONIANS, an aboriginal tribe of South America, who formerly occupied part of the province of Chaco, a country about 300 leagues long and 100 broad, lying about the centre of Paraguay, near the parallel of 28° south. The Mokoby, a powerful tribe, whose relationship to the Abiponians is proved by the resemblance of their language (see ADELUNG'S MITHRIDATES), still inhabit the interior of the province of Chaco, on the banks of the Vermejo and Ypita rivers, which are tributaries to the great Paraguay. The Abiponians, about the beginning of the last century, being defeated by the Mokoby, who were more numerous, placed themselves under the protection of the Spaniards; and finally, to escape from their vindictive enemies, the greater part of them went eastward in 1770, and crossing the Parana river, established the colony of Las Garzas. Here they have retained nearly all their original usages. There are three divisions of the Abipones: the Naquegtgaguehee, the Ruecahee, and the Jaconaiga. When Dobrizhoffer was acquainted with the Abiponians, they were chiefly in Chaco; he describes them as a well-made, tall, handsome race of men, with faces of the European form, and a complexion rather light coloured. Their bodies are robust, capable of enduring fatigue and all the changes of temperature. According to the Jesuit missionary Dobrizhoffer, our chief authority, they are the most wonderful people in the world. An Abiponian, almost a hundred years old, will leap on his horse as nimbly as a boy, and sit there for hours. His teeth and sight are unimpaired at this advanced age; a man who dies at eighty is considered to have come to an untimely end. However, the good missionary remarks that *all* the inhabitants of Paraguay are not quite so wonderful as the Abiponians, for the pedestrian nations are less long lived than the equestrian. One curious feature in the character of the Abiponians is their skill in horsemanship. The horse, as is well known, was introduced into South America by the Spaniards, and from them the Abiponians stole them. They soon became so expert in the management of this animal, that, issuing from their distant retreats, they crossed dry deserts, or extensive swamps, with equal ease and daring, and, after a journey of surprising rapidity, would fall on the Spaniards, when least expected, and massacre all before them. [See *Martin Dobrizhoffer's Account of the Abiponians*, London translation, 1822; Latin original, Vienna, 1784: also in German, 3 vols. 8vo.]

Dobrizhoffer went to South America in 1749, and stayed there eighteen years. His account of the Abiponians is exceedingly minute, and even tedious; and though it no doubt contains many curious and interesting facts, it is not possible to read it without a considerable portion of scepticism; indeed, we do not hesitate to say, that we disbelieve altogether many of the accounts which the good missionary gives: we need only refer to men one hundred years old jumping on horses. Compare Azara's short notice (vol. ii. p. 165) of the Abiponians of Las Garzas.

ABJURATION (*of the Realm*), in law, signifies a sworn banishment, or the taking of an oath to renounce and depart from the realm for ever. By the ancient common law of England, if a person guilty of any felony, excepting sacrilege, fled to a parish church, or churchyard, for sanctuary, he might, within forty days afterwards, go clothed in sackcloth before the coroner, confess the full particulars of his guilt, and take an oath to abjure the kingdom for ever, and not to return without the king's licence. Upon making his confession and taking this oath, he became *ipso facto* attainted of the felony; he had forty days from the day of his appearance before the coroner to prepare for his departure, and the coroner assigned him such port as he chose for his embarkation, to which he was bound to repair immediately with a cross in his hand, and to embark with all convenient speed. If he did not go immediately out of the kingdom, or if he afterwards returned into England without licence, he was condemned to be hanged, unless he happened to be a clerk, in which case he was allowed the benefit of clergy. This practice, which has obvious marks of a religious origin, was, by several regulations in the reign of Henry VIII., in a great measure discontinued, and at length by the statute 21 James I. c. 28., all privilege of sanctuary and abjuration consequent upon it were entirely abolished. In the reign of Queen Elizabeth, however, amongst other severities then enacted against Roman Catholics and Protestant Dissenters convicted of having refused to attend the divine service of the Church of England, they were by statute (35 Eliz. c. 1,) required to *abjure the realm* in open court, and if they refused to swear, or returned into England without licence after their departure, they were to be adjudged felons, and to suffer death without benefit of clergy. So that the punishment of abjuration inflicted by this Act of Parliament was far more severe than abjuration for felony at the common law; in the latter case, the felon had the benefit of clergy; in the former, it was expressly taken away. Protestant Dissenters are expressly exempted from this severe enactment by the Toleration Act; but Popish recusants convict were liable to be called upon to abjure the realm for their recusancy until a statute, passed in the 31 Geo. III. (1791), relieved them from that and many other penal restrictions upon their taking the Oaths of Allegiance and Abjuration.

ABJURATION (*Oath of*). This is an oath asserting the title of the present royal family to the crown of England. It is imposed by 13 Will. III. c. 6; 1 Geo. I. c. 13; and 6 Geo. III. c. 53. By this oath the juror recognises the right of the king under the Act of Settlement, engages to support him to the utmost of the juror's power, promises to disclose all traitorous conspiracies against him, and expressly disclaims any right to the crown of England by the descendants of the Pretender.

ABLANCOURT (PERROT NICOLAS D'), one of the most esteemed translators of the classic authors, in the seventeenth century, was born at Châlons sur Marne, in Champagne, (now in the department of the Marne,) in 1606, and died of the stone at Ablancourt in November, 1664; but not of voluntary starvation, on account of the pains of his disorder, as is said in the *Menagiana*. His family was honourable, and greatly esteemed at the bar. His father bestowed the most anxious care on his education, with the view of uniting the advantages of public and private education; and in this he succeeded, for his son advanced most rapidly in his classical studies. Ablancourt commenced his career at the bar, but quitted it almost immediately for literary pursuits; and at the same time abandoned the Protestant creed, in which he had been brought up, to the great delight of the Catholic members of his family. He returned, however, to his first belief; for six years afterwards, his conscience not being quite at rest, he studied with the deepest attention under the learned Stuart for three years, at the end of which time he abjured the Roman faith, and immediately after retired into Holland, to be near the learned Saumaise, and enjoy the society of that famous scholar; perhaps, also, to let the scandal of his second abjuration die away. It is only fair to state, that on neither occasion was he influenced by any worldly consideration whatever. From Holland he repaired to England, and from thence to Paris, where he became intimately acquainted with Patru, one of the most celebrated writers and distinguished lawyers of that day, and also with other eminent literary characters. In 1637, (the *Biograph. Univ.* says, by mistake, 1627, the Académie Françoise having been established only in 1634-35,) he was received a Member of the French Academy, and gave his whole attention to the translation of the works of Tacitus; but being soon obliged to quit Paris on account of the war which broke out, he went to reside at his seat at Ablancourt, in Champagne, for the remainder of his life, with the exception of the time he spent in Paris during the printing of his works. Ablancourt had so lively an imagination, that his friends wondered at his being only a translator; but his reason for being so was, according to his own account, that there were already too many modern works deficient in truth and novelty, in which princes could not learn their duties so well as in the ancient writers. D'Ablancourt might have quoted Mezerai and several others as exceptions to that remark. Of his numerous translations those most known are, the whole of Tacitus, of which there have been ten editions; four orations of Cicero; Cæsar; and the Wars of Alexander by Arrian, the most esteemed of his translations as regards the style only; Thucydides; the Anabasis of Xenophon; and an imitation, rather than a translation, of Lucian. As to the accuracy of the translations of Ablancourt, when compared with those of the last century, and still more with those of the present, they are decidedly inferior to both; and even during the life of the author, admired as he was, and destined to immortality according to the opinion of his friends and the public at large, they were denominated *belles infidèles*. They were intended for what is called the 'fashionable world;' and it was then the notion of that class that everything ought to be Gallicised; which is, in truth, the great fault of many branches of French literature in the seventeenth century.

D'Ablancourt entered so well into the taste of his readers that everything, even in geography, is modernised in his translations; as, for instance, Germany becomes Allemagne; Caledonia, Scotland; Britannia, England; the Batavians, Hollanders: and, in the Life of Agricola, the description of *Britain* is introduced in this manner—'*England* is the largest of the islands which are known by us; it has *Allemagne* to the orient, and to the occident *Spain*, and *France* to the south.'

Though this notice is not very long, we may perhaps have extended it beyond what this author deserves, considering his degree of merit; but Ablancourt, during his lifetime, was held in high estimation, which still prevails to a certain degree in France, and perhaps in England also. His life has been written by his friend, Patru. In 1662, Colbert proposed him to Louis XIV., as the historian of his reign, but Louis would not have a Protestant to commemorate the events of his reign. However, he did not deprive him of his pension of 120*l.* per annum, which had been granted to him as historiographer. The revocation of the Edict of Nantes had not yet been proclaimed.

ABLATIVE CASE, a term borrowed from the grammatical system of the Latin language, and occasionally employed in teaching our own. In the English language there are many little words, such as *with*, *in*, *to*, *at*, &c., which are called *prepositions*, because they are *preposed* or prefixed to the words with which they are connected. The name, however, is an unfortunate one, as they are sometimes found *postponed* or placed after such words, especially in the older specimens of our language. We say *with which* or *wherewith*, *in which* or *wherein*, *from which* or *wherefrom*. So, in the Latin language, a certain set of little words, with the force of prepositions, were tacked on to the end of their nouns: thus, while the three letters, *reg*, meant *king* (whence our word *reg-al*), *reg-is* meant *of* or *from a king*—*reg-i*, *with*, *in*, or *near a king*—*reg-em*, *to a king*. Thus the three little words, *is*, *i*, *em*, were equivalent to prepositions. It pleased the grammarians, however, who are fond of multiplying names, to call these words *reg-is*, *reg-i*, &c., by the name of *cases*. The meaning of the endings of these words was not always definite enough. Thus with the case in *i*, for instance, it was found necessary to mark the relation of place more precisely by the addition of other words, as *in*, *in*—*pro*, *before*—*cum*, *with*. Thus they would have, *in regi*, *in the king*; *pro regi*, *before the king*; *cum regi*, *with the king*. Now, as *in*, *pro*, *cum*, were much more definite than the termination *i*, it became unnecessary to make the *i* distinctly heard. It was no longer necessary to the meaning, and might, therefore, be slurred over: hence the pronunciation was reduced to *in rege* (the last *e* very faintly pronounced), *pro rege*, *cum rege*. It would seem as if the termination *is*, signifying *of*, or *from*, was treated in the same unceremonious manner, for we find *ex rege*, *out of the king*; *ab rege*, *from the king*; *de rege*, *down from the king*; where we might have expected *ex reg-is*, *ab regis*, *de regis*. But, as we said above, *ex*, *ab*, and *de*, being more precise in meaning than the little appendage *is*, the distinct pronunciation of the former rendered that of *is* superfluous, and consequently the little *is* dropped into a weak *e*, as before. Now this termination *e*, affixed to the Latin nouns, received from the grammarians the name of *ablative case*, i.e. the *case* of *removal*; which applies, indeed, well enough to *ex rege*, *out of the king*; *ab rege*, *from the king*, &c.; but is not well suited to the ideas, *cum rege*, *with the king*; *in rege*, *in the king*, &c. But the grammarians who invented these hard names seldom saw more than half of the question before them. For fear, lastly, that any of the learned should find fault with our Latin, we will observe that even the little *e* which marks the ablative case, which *e* itself is but a remnant of a longer termination, was often absorbed by a preceding vowel in the Latin word to which it was attached. Thus, to take *regina*, *a queen*, they did not say *in reginae*, *cum reginae*, *ex reginae*, &c., but *in regina*, *cum regina*, *ex regina*, &c. When the term 'ablative case' is used in English grammar, it is only an awkward name for the preposition *from*.

ABLUTION, literally *a washing away*—a religious ceremony, consisting in bathing the body, or a part of it, in water, which has been practised more or less extensively by the disciples of almost every form of faith. In the earlier and ruder states of society especially, there is a strong tendency to endeavour to invest the spiritualities of religion with what we may call a visible and substantial form, so that they may be apprehended not only by the reason, but also by the senses. Of this disposition the master minds who have founded and reared the various systems of superstition that have held sway in different countries and ages of the world, have usually taken advantage, as a chief instrument whereby to work upon the gross natures to which they had to address themselves, and to intwine the desired belief at once with their affections and with their habits. Among such outward types, none can be conceived more natural or appropriate than that of washing the body with water as a sign or attempted representation of mental purity. The custom, particularly in the warm climates where it was first introduced, had also the further advantage of being highly conducive to health; and this circumstance no doubt contributed powerfully to recommend it to the authors of many of the religions by which it was sanctioned and enjoined. Ablutions, or lustrations, as they are more commonly called, even constituted a part of the Mosaic ceremonial, and were practised among the Jews on various occasions both by the priests and by the people. They occupy an important place in the Brahminical and other religions of India, where the waters of the Ganges are considered as having so purifying a power, that even if a votary, who cannot go to that river, shall call upon it to cleanse him, in prayer, while bathing in another stream, he will be freed from any sin or pollution he may have contracted. But the religion by which ablutions have been enjoined most punctiliously, and in the greatest number, is the Mohammedan. According to the precepts of the most rigid doctors of that faith, it may almost be said that scarcely the most ordinary or trifling action can be rightly performed without being either preceded or followed by an entire or partial lustration. The rules laid down upon the subject by these writers are minute and tedious, to a degree scarcely to be believed. The simple ceremony of the Christian baptism may be regarded as an adoption of this natural type by the Author of our faith. Although, however, that is the only instance in which dipping in or sprinkling with water has been enjoined under the dispensation of the New Testament, the early Christians appear to have been also in the habit of undergoing ablution with water, before partaking of the communion. The sprinkling with holy water, in use in the Catholic church, may be considered as a species of ablution; and that term is also applied both to the water in which the priest, who consecrates the host, washes his hands, and to a drop of wine and water which used anciently to be swallowed immediately after the holy wafer.

ABO, in N. lat. 60° 27′, E. long. 22° 15′, near the angle formed by the gulfs of Bothnia and Finland, is a town of the great principality of Finland, now part of the Russian empire. Abo is in that part of Finland which once belonged to Sweden, and it then was the chief city of all Finland. It stands on the Aurajoki river, and is surrounded by hills and mountains. In its neighbourhood is a mineral spring. The number of inhabitants is 12,550. The manufactures of Abo are tobacco, sugar, sail-cloth; and it trades in provisions and deals. There are also dockyards here. The fort of Abohus protects the entrance of the river, which does not admit vessels of large size to go up as far as the town. In the year 1827, seven hundred and eighty houses were destroyed by fire, together with the University buildings, the library, and all the valuable collections. Since this accident, the University has been removed to Helsingfors. (See Helsingfors.) Gustavus Adolphus, in the year 1628, founded this University, or rather instituted an Academy, which Christina, in 1640, elevated to the rank of a University. Alexander I. of Russia added to the endowments. (*Cannabich's Geography, German.*)

Many of the treaties between the great European powers are distinguished by the names of the places at which they were concluded. Thus, the *Peace of Abo* is often referred to in history, as the treaty by which the relations of Sweden and Russia were determined during the latter part of the last century.

A congress was opened at Abo in March, 1743, by the plenipotentiaries of Sweden and Russia, to confer on conditions of peace between those powers. The war, which it was the object of this conference to put an end to, had been commenced in 1741 by Sweden, who, still smarting from the concessions she had been compelled to make to Peter the Great by the treaty of Nystadt in 1721, took advantage of the war between Russia and Turkey to conclude an alliance with the latter power against Russia. The war was most disastrous to Sweden: the hopes she had conceived of assistance from Turkey were frustrated by the peace of Belgrade between Russia and the Porte, her best soldiers were defeated, and her armies in Finland destroyed in the first campaign.

The revolution in Russia, by which Ivan was dethroned, and the daughter of Peter set upon the throne, occasioned a suspension of arms, but in 1742 hostilities began again; Sweden was again defeated, and all Finland abandoned to the Russian arms.

The Swedish Diet met, and deliberated on offering the succession of the throne of Sweden to the Prince Royal of Denmark. Russia, fearing the union of the crowns, offered peace, and restitution of her conquests, on condition of the Diet's choosing Adolphus Frederic of Holstein Gottorp as the successor of the reigning king, Frederick, who was childless. The condition was accepted, and the election took place on the 4th of July, 1743.

By the stipulations of the treaty, which was signed on the 18th of August, N.S., Sweden renewed her cession of Ingria, Livonia, and Esthonia, which had been given up by the treaty of Nystadt, and was also compelled to yield the eastern portion of Finland, making the river Kymmene the boundary of the two nations. Russia restored the rest of the Grand Duchy, which she had gained in the war, including Abo, Biorneborg, and East Bothnia. It may be necessary to mention that the whole of Finland was ceded to Russia by a peace concluded between the two powers, on the 17th of September, 1809.

ABOMA, a large species of serpent, which inhabits the fens and morasses of South America. (See Boa.)

ABORIGINES, a term by which we denote the primitive inhabitants of a country. Thus, to take one of the most striking instances, when the continent and islands of America were discovered, they were found to be inhabited by various races of people, of whose immigration into those regions we have no historical accounts. All the tribes, then, of North America may, for the present, be considered as aborigines. We can, indeed, since the discovery of America, trace the movements of various tribes from one part of the continent to another; and, in this point of view, when we compare the tribes *one with another*, we cannot call a tribe which has changed its place of abode, aboriginal, with reference to the new country which it has occupied. The North American tribes that have moved from the east side of the Mississippi to the west of that river are not *aborigines* in their new territories. But the *whole mass* of American Indians must, for the present, be considered as *aboriginal* with respect to the rest of the world. The English, French, Germans, &c., who have settled in America, are, of course, not *aborigines* with reference to that continent, but settlers, or colonists.

If there is no reason to suppose that we can discover traces of any people who inhabited England prior to and different from those whom Julius Cæsar found here, then the Britons of Cæsar's time are the aborigines of this island.

The term aborigines first occurs in the Greek and Roman writers who treated of the earlier periods of Roman history, and, though interpreted by Dionysius of Halicarnassus to mean *ancestors*, it is more probable that it corresponds to the Greek word *autochthones*. This latter designation, indeed, expresses the most remote possible origin of a nation, for it signifies 'people coeval with the land which they inhabit.' The word *aborigines*, though perhaps not derived, as some suppose, from the Latin words *ab* and *origo*, still has the appearance of being a *general* term analogous to *autochthones*, and not the name of any people really known to history. The *aborigines* of the ancient legends, interwoven with the history of Rome, were the inhabitants of part of the country south of the Tiber, called by the Romans Latium, and now the Maremma of the Campagna di Roma; but we are, in truth, unable to say to what people this term may be properly applied. [See *Niebuhr's Roman History*.]

ABOU-HANNES (*Numenius Ibis*, Cuvier; *Tantalus Æthiopicus*, Latham), an African bird, which has occasioned much discussion among the learned as to its identity with the ancient Ibis. The attention of Bruce was attracted, during his stay in Upper Egypt, by some birds called by the natives Abou-Hannes, whose forms reminded him of the ibis, as represented on Egyptian monuments, and repeated observation confirmed him in the opinion of their identity with the ibis of the ancients. This identity was subsequently corroborated by the distinguished naturalists, Geoffroy and Savigny, who accompanied the French expedition into Egypt, and procured a number of specimens. M. Savigny published his observations in a small work (*L'Histoire Nat. et Mythol. de l'Ibis*), now very scarce, and Baron Cuvier also gave a memoir on the Egyptian ibis in the *Annales du Muséum* for 1804, in which he has clearly proved, from the comparison of a mummy ibis with a stuffed specimen, that the true ibis is not the *Tantalus ibis* of Linnæus, that being a much larger bird, but is really a species of curlew. This bird appears to be also a native of regions very remote from Egypt. After just getting round Cape Guardafui (sailing from the south), Salt saw, near the coast, a lagune abounding in wild fowl,—'on the borders of it stood birds of a species called by the Arabs, Abou-Hannes, which is the true Ibis of the Egyptians, as described by Herodotus; a fact strongly marked by the head and neck being bare, and of a deep black colour. It may be worthy of remark that Strabo mentions this bird as frequenting the coast to the east of the Straits of Babelmandeb.' (Salt, p. 97.) He adds, in a note, 'a tolerably good specimen of the bird is to be seen in Mr. Bullock's valuable Museum.'

[True White Ibis.]

Herodotus attributes the veneration of the Egyptians for the ibis, to supposed services rendered them by the bird in freeing their country from winged serpents. That the ibis, however, could not feed upon serpents appears nearly certain from anatomical inspection. The bill, for example, being long, slender, considerably curved, blunt on the edges, and expanded, and roundish at the point, could neither divide nor pierce serpents; and indicates rather an aptitude to dabble in marshy and moist grounds.

On the other hand, Baron Cuvier found, in the mummy of the ibis, remains of the skin and scales of serpents, and hence it has been inferred that the birds might have been serpent-eaters (*Ophiophagæ*). This inference, however, is at variance with the observations made in Egypt by M. Savigny on a great number of individuals, in the crops of which he uniformly found land and fresh-water shells (*Cyclostomata, Ampullariæ, Planorbæ, &c.*), and these shells were always entire when their inhabitants had not been previously digested.

It does not appear that the ibis breeds in Egypt; but, on the testimony of the inhabitants, it arrives as soon as the waters of the Nile begin to rise, augmenting in numbers as the waters increase, and diminishing as they subside, and disappearing when the inundation terminates. These birds, on their arrival, repair to the low lands, which are first covered with water; but when the waters become deeper and spread wider, the birds betake themselves to the higher lands. They afterwards approach the river, where they establish themselves by the sides of the canals and on the small dykes, with which the greater part of the cultivated grounds are surrounded.

The bird in question sometimes lives solitary, sometimes in small troops of from eight to ten. Its flight is lofty and powerful, and it utters at intervals hoarse cries. When it alights on a fresh piece of land, it remains for hours together occupied in tapping the mud with its bill, in search of worms, &c. It walks leisurely step by step, and has not been observed to run, like our curlew (*Numenius arquata*, Latham), to which it otherwise bears some resemblance.

The Egyptians call the bird *Abou-menzel*, which literally means 'Father sickle-bill;' the bill being curved like a sickle. The Æthiopian name, *Abou-Hannes*, means 'Father-John,' because, as M. Dumont supposes, the birds arrive about St. John's day.

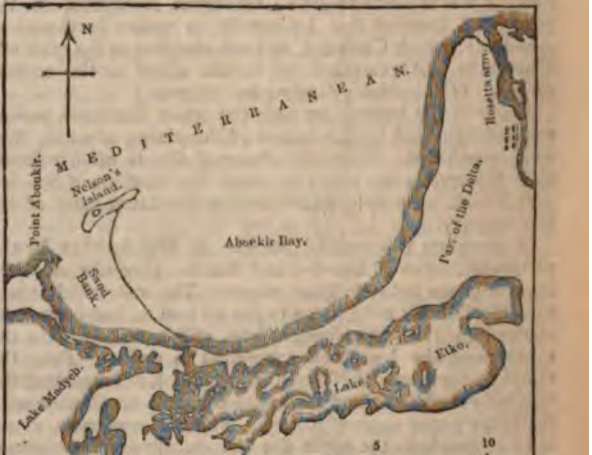
The following is the earliest account that we have of the ibis, from an eye-witness (Herodotus ii. 76):—'The ibis is all over very black: it has the legs of a crane, and a beak considerably curved: its size is about that of a *crex*. Such is the appearance of the black ibis, which fights against the serpents. But the other ibis, which is more of a domestic bird (for there are two kinds), has the head and all the neck bare of feathers: it is of a white colour, except the head, neck, and the extremities of the wings and tail, all which parts are very black. As to its legs and beak, it resembles the other kind of ibis.' The black ibis, according to Herodotus, devoured the winged serpents which yearly attempted to make their entry into Egypt from Arabia. It is needless to add that these winged serpents are a fable. Strabo, who himself was some time in Egypt, gives the following account:—'The ibis is the tamest bird of all: in form and size it is like the stork. But there are two varieties of colour, one of which is that of the stork, and the other is all black. Every street in Alexandria is filled with them, partly to the benefit of the citizens, and partly not. The bird is useful so far as it devours all kinds of vermin, with the garbage of the shambles, and the refuse of the eating-houses, &c.' Here Strabo makes no distinction between the two, except in colour, and he describes both species as living on all kinds of garbage. We believe, however, he has confounded the real ibis and the stork, as Hasselquist, a Danish traveller, confounded the real ibis and the heron. [See IBIS.]

ABOU-HARB, in Arabic, the name of the Leucoryx antelope.

ABOU-HOSSEIN, according to Rüppel, a late German traveller in Egypt and Nubia, the Arabic name of the *canis pallidus*, a small species of fox, found in Dar-Foor and Kordofan.

ABOUKIR. The castle of Aboukir (N. lat. 31° 19′, E. long. 30° 6′, and about thirteen miles N.E. of the town of Alexandria) is on the extreme north-eastern point of the low barrier of limestone rocks that form the breastwork of the coast of Alexandria. It marks, in fact, the extreme eastern limit, along the northern coast, of the rocks of the African continent, being immediately followed by the old Canopic mouth and the alluvium of the Delta. It is not unlikely that Aboukir castle is near the site of an ancient city, but whether this city was Canopus or not, we think it is impossible to decide, as the coast has undergone very great changes. Canopus, however, could not be more than a few miles distant from Aboukir, probably on the east side.

The small island which lies near Aboukir point contains traces of old buildings, and also evident marks of having once been larger than it is at present. This little spot is now commonly called Nelson's island, in commemoration of the victory which the English admiral obtained over the French fleet, under Brueys, in Aboukir bay, August 1, 1798 (see NELSON). Aboukir bay may be considered as bounded by Aboukir point on the south-west, and by the neck of land at the outlet of the Rosetta arm on the north-east.



ABOUSAMBUL, IPSAMBUL, or EBSAMBUL, a place remarkable for containing two of the most perfect specimens of Egyptian rock-cut temples. These excavations are in Nubia, on the west side of the Nile, N. lat. 22° 22′, about twenty-six geographical miles north of the cataracts of Wady Halfa. Near Abousambul the river flows from south west to north-east, through sandstone hills; on the west bank a valley opens and displays two faces or walls of rock, each of which has been fashioned into the front of a temple. The excavations are made in the solid mass of the mountain.

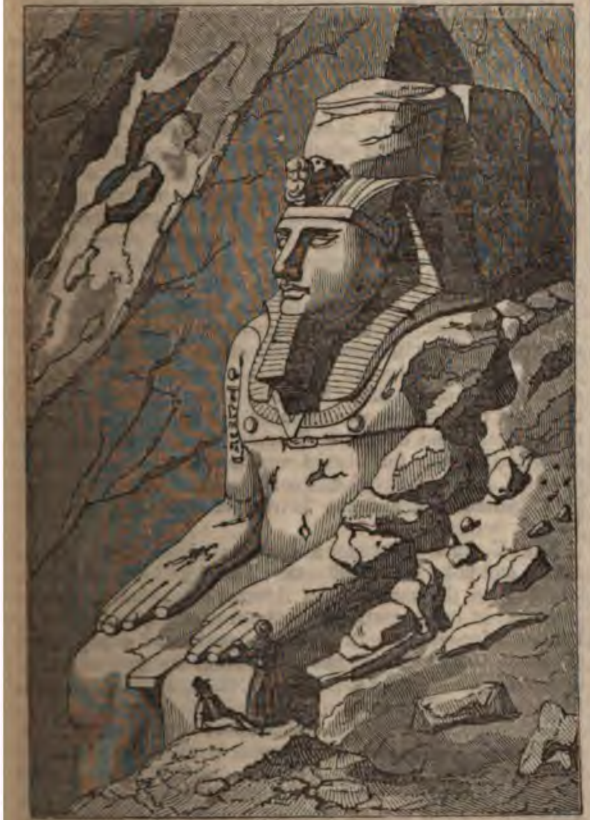
The smaller temple was first described by Burckhardt, who gave it the name of the Temple of Isis. It stands 20 feet above the present level of the river, is free from all incumbrance of dust or rubbish, and in a state almost as perfect as when it was just completed.

The façade of this excavation is the exact prototype of those masses of Egyptian architecture, called *propyla*: the face slopes outwards towards the base, thus preserving one chief characteristic of the pyramidal style of building. On each side of the door-way are three standing colossal figures, about 30 feet high, cut out of the rock, and deep sunk in niches; to the back part of which they are attached by a portion of the rock that has been allowed to remain. The figures have, as usual with Egyptian statues in a standing position, one foot advanced; they look towards the river. On each side of the larger figures stand smaller ones, from 4 to 6 feet high: we believe this is the case with all of them, though the print in Gau's splendid work on Nubia does not exhibit any smaller figures attached to the central one on each side, which is a female, and probably the representative of Isis. These smaller figures, however, appear in Gau's geometrical elevation. (pl. 54.) The two male figures, on the right side of the doorway, are probably Osiris: that nearest to the door, on the left hand, is the same; while the other male figure on this side has a different head-dress and expression of countenance, and is also an Osiris. He has horns on his head, supporting a disk. The whole façade is ornamented with hieroglyphics; among which we perceive several elliptical rings, which, it is now ascertained, contain the names and titles of kings. The rings on this temple present, with several variations, the name of Ramses, one of the several ancient monarchs of Egypt, who bore that name. If we consider the name to be that of Ramses the Great, the date of this excavation will be about B.C. 1500, provided we admit the inscription to be contemporary with the excavation—an hypothesis, however, that wants confirmation. It is not at all unlikely that the original excavation is of much higher antiquity than the sculptures of the outside, and the painted bas-reliefs of the interior.

The width of the front of this temple is about 90 feet: the depth measured from the centre of the door-way to the extremity of the adytum is 76 feet. From the door a passage leads to a room 35 feet by 36½, supported by six square pillars, three on each side, with Isis-headed capitals, similar to those of Denderah. From this apartment we pass into a narrow kind of vestibule, the direction of whose length is at right-angles to the axis of the excavation; and thence into the adytum or recess, which contains the remains of a sitting statue cut in the rock. There are two other small chambers besides those enumerated, one at each end of the vestibule just alluded to. The interior of this excavation is richly adorned with painted bas-reliefs, representing offerings of palm-branches and the lotus to Osiris, with other subjects usually found in the Egyptian sculptures. The figures are painted yellow with black hair; the head-dress of Isis is painted in black and white stripes; the ceiling is blue, which is a favourite colour for ceilings in the ancient buildings of Egypt.

But this excavation, magnificent as it is, sinks into insignificance when compared with another rock-cut temple, which is found a few hundred feet distant in the opposite side of the valley. The front of this temple was almost covered with sand, except the head and shoulders of one of the four colossi which decorate the façade, and the frieze and head of an enormous hawk. Belzoni, in the year 1817, with the assistance of Captains Irby and Mangles, and the aid of the miserable natives, succeeded in finding the entrance; but he had to remove 31 feet of sand before he came to the top of the door.

This excavation is about 100 feet above the level of the river, and faces south-east by east. The width of the front is 117 feet (127 according to Colonel Stratton), and 86 high: the height from the top of the door to the top of the cornice is 66 feet 6 inches; the height of the door is 20 feet. There are four enormous sitting colossi in front, which are the largest in all Egypt or Nubia.



[One of the Colossi of Abousambul.]

The following are some of the dimensions of this enormous figure: 25 feet 4 inches across the shoulders, the face 7 feet long, the nose 2 feet 8 inches, the beard 5 feet 6 inches; the whole height, as it sits, is about 50 feet, besides the cap, which is 14 feet high. Only two of these monsters are in sight; a third is buried in the sand, and the fourth has partly fallen down from the rock to which he was attached by the back, and is also covered. From some traces of colour on these figures, it seems probable that they were once painted, according to the Egyptian fashion. Over the door there is a figure in relief of Osiris, 20 feet high, in a niche, and with two colossal figures, one on each side looking towards it. The highest part of the façade is formed by a cornice, ornamented with hieroglyphics, and a moulding and frieze below it. Above the cornice is a row of twenty-two monkeys seated, about 8 feet high, and 6 across the shoulders.

The depth of the temple is about 170 feet. It contains in all fourteen apartments; but its several arrangements may be best understood, in the absence of a plan, by considering it as containing four principal chambers behind one another, with a number of attached apartments. To form anything like an adequate notion of this enormous excavation, it is necessary to consult the special descriptions to which we refer at the end of this article; but the following description of the Pronaos, or first great chamber, may serve to give some idea of the colossal dimensions of the whole. The first chamber is 57 feet long, and 52 wide, and is supported by two rows of square pillars, four in each row; each side of the pillars measures, according to some accounts, 5 feet, according to others 8 feet. Their height, according to Belzoni's account, is 30 feet. To each pillar is attached by his back a standing colossus, which, reaching the roof with its high cap, appears to support the incumbent mass. These figures are described as bold in their execution, and as producing an agreeable effect. Their arms are crossed on the breast; in one hand they bear the key of the Nile, and in the other the scourge. These statues are entirely covered with a kind of stucco, which is richly painted with various colours.

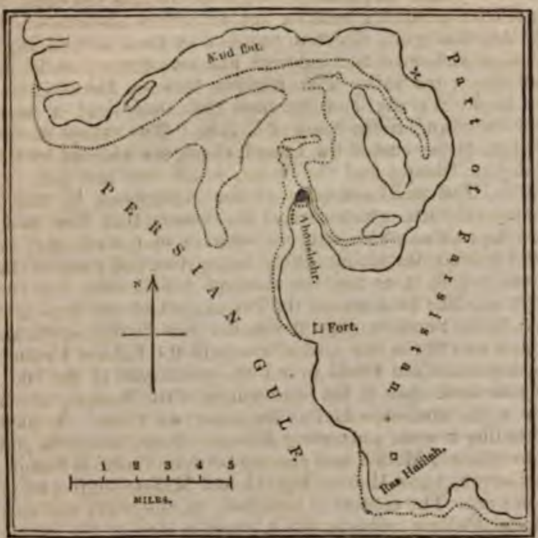
The painted walls, which represent a hero of colossal size gaining a victory over his enemies, triumphing, &c., are well worth a careful study, not only as works of art which possess merit in their way, but from the resemblance, in many respects, of the events here depicted to the battle-scenes represented on the walls of Thebes. They appear to be the records of great achievements, such as tradition assigns to Sesostris, who is now generally considered to be identical with Ramses the Great. The name and title of the latter monarch are found in many parts of the temple; and if he was not the original excavator, he may, perhaps, be considered, at least, as the completer of this great design.

In the adytum, or last chamber of the four above-mentioned, which is 23½ feet long, and 12 wide, there are four colossal painted figures seated at the extremity: in the centre of this room is a pedestal. Heeren conjectures that a sarcophagus once stood on this pedestal, and that we ought to consider this huge excavation not a temple, but a tomb.

The name Abousambul is variously written at the present day, and the origin of it is somewhat obscure. It seems most probable that it contains the syllable *Psam* (the name of a deity), which we observe in several Egyptian names, such as Psammis and Psammetichus. [See *Gau's Monuments of Nubia—Belzoni's Operations in Egypt and Nubia — Ritter's Africa—Col. Stratton, Edin. Phil. Journal—Egyptian Antiquitys of this Society.*]

ABOU-SCHOM, the Arabic name of a species of fox (*canis variegatus*) [Rüpp. *Zool. Atl.*, p. 31], discovered by Rüppel in Nubia and Upper Egypt. It does not burrow under ground, like the generality of foxes; but, like the jackall, resides among the rocks and deserts, and feeds upon lizards and small quadrupeds.

ABOUSHEHR, generally called **BUSHIRE**, is a town on the east side of the Persian gulf (N. lat. 28° 57′, E. long. 50° 52′), and now the principal sea-port in these waters. It stands on the northern extremity of a sandy peninsula, which is washed by the sea on the west side, and on the north and north-east bounded by an indentation of the sea, forming a deep bay. The country all around Bushire is parched and barren, showing nothing but grey clay, brown sand, and rock, without any kind of vegetation. Though the town looks pretty well from the sea, like most Persian towns the interior disappoints expectation, as the place does not contain more than half a dozen decent houses, which are built of sun-dried bricks. Since the decline of Bunder Abbas, or Gombroon, Bushire has become the great Persian emporium for the Indian trade, and its commerce is now considerable. Bullion and raw silk are the principal articles of export. Vessels of 300 tons cannot approach nearer the town than six miles. The population is probably as much as 10,000. [See *Kinneir's Memoir on Persia.*]



From Bushire to Shiraz in the interior, through which place a great part of the trade of Bushire passes, is a distance of about 152 miles following the road through Kazeroon, which, in many parts, is exceedingly steep and rugged.

ABOUSIR, a place in the Egyptian Delta on the site of the ancient Busiris (N. lat. 30° 55′), near the left bank of the Damietta branch of the Nile. Like most of the sites of ancient cities in the Delta, it has preserved its name almost unchanged, and enough still remains to show that a temple once existed here, as we know from Herodotus, though its traces are insignificant when compared with those of San, Tel Basta, and Heliopolis.

ABRAHAM (originally ABRAM), the great ancestor and founder of the Jewish nation, and the first depositary of the divine promises in favour of the chosen people. He was the eldest son of Terah, the eighth in descent from Shem, the eldest son of Noah, and was born, probably, at Ur, a town of Chaldæa, about 2000 years before the Christian era. His history occupies about a fourth part of the book of Genesis—namely, from the 11th to the 25th chapters inclusive. Having married Sarah (originally Sarai), his sister by the father's side, he accompanied his father and his nephew Lot to Haran, where Terah died; and then, at the command of God, still taking his wife and Lot along with him, he left Haran, and proceeded towards the south, till he reached the plain of Moreh, in Canaan. The epoch of the commencement of this journey, which happened when he was seventy-five years old, is called by chronologists the Call of Abraham. Soon after, a famine forced the patriarch to make a journey into Egypt; from which country, when he had returned to the place of his abode in Canaan, he found that the increase of his own flocks, and those of his nephew, made it necessary that they should choose separate settlements; and, accordingly, by mutual consent, Lot withdrew towards the east, and established himself among the cities in the plain of Jordan, while Abraham removed to the plain of Mamre in Hebron. He had reached his ninety-ninth year, and his wife, who had been hitherto barren, her eighty-ninth, when God appeared to him, and declared that there should yet spring from them a great nation: a promise which was confirmed, to the almost incredulous mother, by the birth of Isaac the following year. The severe trial of Abraham's faith, in the command given him to sacrifice this beloved son, so beautifully related in the 22nd chapter of Genesis, is familiar to every reader. Some time before this, we may remark, he had given another striking proof of his submission to the divine will, and his implicit reliance on the promises of God, in his dismissal of his son Ishmael, whom he had by Hagar, the Egyptian bondwoman, on the assurance of his heavenly father, that of him, too, would he make a nation, because he was the patriarch's seed. Although Sarah's determination, that the bondwoman and her offspring should no longer remain in the house, 'was,' we are told, 'very grievous in Abraham's sight, because of his son,' he had no sooner received the above intimation from on High, than he 'rose up early in the morning, and took bread, and a bottle of water, and gave it unto Hagar, putting it on her shoulder, and the child, and sent her away.' The Arabs claim to have sprung from Ishmael, as did the Hebrews from Isaac. After the death of Sarah, at the age of 127, Abraham married Keturah, and by her had other six sons. The venerable patriarch died at the age of 175, and was buried, by Isaac and Ishmael, in the same tomb which contained his first wife in Mamre. Abraham is mentioned by the epitomist Justin, who, on the authority of his original *Trogus Pompeius*, inaccurately says of the Jews, that they derive their origin from Damascus, a famous city of Syria, and that their kings were Abraham and Israel.

ABRAHAM MEN. 'To sham Abraham' is a well known cant expression, which has reference to the practices of a large class of vagabonds and cheats who were once common in this country. An Abraham Man was an impostor who personated a 'Tom of Bedlam,'—an unhappy being who was turned out of a lunatic hospital to subsist upon casual alms, incurable but harmless, without a home, but still maintained by public sympathy. This class of persons was so numerous at a period when there was very insufficient provision for the cure or mitigation of the greatest of human calamities, that the charity of the kind-hearted inhabitants of the small towns and villages was largely taxed for their support; and the appeal thus made to the feelings by a poor creature, fantastically clothed in tawdry rags, and singing snatches of old songs, was so irresistible, that it became a profitable trade to imitate such an unfortunate being. In Decker's *English Villanies*, written more than two centuries ago, there are many curious particulars of the habits of this class of impostors; these details, in great part, agree with the rich description which Shakspeare has given in his *Lear* (Act ii. scene 3.) of a pretended 'Poor Tom,' who has put on

> 'The basest and most poorest shape,
> That ever penury, in contempt of man,
> Brought near to beast.'

[See D'Israeli's *Curiosities of Literature*, vol. iii.]

ABRANTES, a fortified town of Portugal, in the province of Estremadura, on a hill near the Tagus (N. lat. 39° 27′, W. long. 8° 11′), 74 miles north-east of Lisbon. It has about 5000 inhabitants. The eminence on which the town stands is covered with olive-yards and gardens; and, indeed, the whole country along the Tagus, as far as Lisbon, is exceedingly fertile. Abrantes has several churches and convents; but its value, as a military position, constitutes its chief importance. Abrantes gave the title of Duke to Marshal Junot, one of Buonaparte's generals.

ABRUZZO, a name given to three of the fifteen divisions of the kingdom of Naples in Italy: the *Abruzzo Ultra*, or Further Abruzzo 1 and 2, and the *Abruzzo Citra*, or the Nearer Abruzzo. They are thus distinguished from their relative position with regard to the capital, Naples.

The Further Abruzzo 1 contains about 1143 English square miles, and (1825) 174,370 inhabitants, who are one of the most industrious manufacturing people in the kingdom of Naples. The capital is Teramo, on the Tordino, with 6000 inhabitants: this district contains also the considerable towns of Atri and Cività di Penna, each of which has about 9000 inhabitants, and the fortress of Civitella, near the Roman frontier.

The Further Abruzzo 2 contains about 2220 square miles, and 259,114 inhabitants. The chief town is Aquila, on a hill on the banks of the Aterno, otherwise called the Pescara: it has a castle, manufactures of paper, stockings, leather, a lyceum, a high court of appeals, and a population of about 10,000 inhabitants. Sulmona, the ancient Sulmo and the birth-place of Ovid, and Celano, about four miles from the lake of the same name, belong to this province.

The Nearer Abruzzo contains about 1700 square miles, and 260,250 inhabitants, who possess considerable manufacturing industry. Chieti or Teti, the ancient Teate, near the Pescara, is said to have above 12,000 inhabitants. The Theatine order of monks, founded in 1524, take their name from this place. The fortress of Pescara and the towns of Ortona on the sea, and Lanciano on the Foltrino, belong to this division of the Abruzzi.—(*Cannabich's Geog.*)

The origin of the name Abruzzo is uncertain. Some would derive it from the Prætutii, a nation that formerly dwelt near the eastern coast. The form in which the word appears in the oldest Italian writers is Bruzio, the *a* in the beginning of the modern name being no efficient part of it.

The provinces of the Abruzzi present to the Adriatic a coast about eighty miles in length, with hardly an indention or projection that deserves notice, except the point called Penna, and not a single harbour for moderate-sized vessels. The northern boundary, between the States of the Church and the Abruzzi, commences at the mouth of the Tronto. Running irregularly westward, and then south, it strikes the river Velino near Rieti; from this point its general direction, which is south-east, follows a high mountain range, which, however, must not be considered as the dividing line of the waters that fall into the Adriatic and the opposite or Tuscan sea. The southern boundary of the Abruzzi commences near the mouth of the Trigno, half way between the towns of Vasto and Termoli on the Adriatic coast, and, after a short deviation from the course of this stream, follows it upwards for some distance. It then runs, irregularly, westward and northward, nearly parallel to the course of the Sangro, and keeping along the summit of the high central ridge that divides the waters of this river from those of the Volturno, it then descends into the valley of the Liris, which river it crosses above Sora, where we may consider it as uniting with the line just described running south-east from Rieti. A traveller going from Arpino (Arpinum), the birth-place of Cicero, to the Lake Celano, must cross the Liris, and the first village in the Abruzzi that he will come to, is a little place called Balzerano. Around this place the mountains are lofty and well wooded, containing oaks of a larger size than usual in Italy; some of the mountains on the 6th of May, according to Colt Hoare, were capped with snow. From Balzerano the road runs along the mountain sides, through rocks and oak forests, and over the high eminence of Morrea, to the still greater elevation of Antino, a place remarkable for remains of its original walls, built without cement, and for many Roman inscriptions, which prove the Roman name of the town to have been Antinum. From Antino to Capistrello, the valley of the river becomes so narrow, as to admit only a passage for the water, and a road along the brink. The traveller, ascending along this wild and picturesque track, perceives that he is approaching the sources of the Liris, and the basin of the lake Celano. This lake, the Fucinus of the Romans, is only a short distance from Capistrello: its greatest length is about fifteen miles, with a breadth averaging about five or six. It is subject to rises and falls, which are difficult to explain, and, indeed, without more information on the subject than can be found in books of ordinary access, there is no use in hazarding any opinion. It is said to contain many fish. The Emperor Claudius undertook a great work for the purpose of draining the lake, or, at least, preventing it from doing damage by overflowing. Suetonius says of it, 'he undertook the Fucine lake, no less from the hope of speedily completing the task, than from the love of glory. Some private individuals had already offered to construct the necessary drain, on condition of having the lands that were recovered. Claudius made a canal three miles long, partly by perforating and partly by cutting down a mountain. It was finished in eleven years, thirty thousand men having been constantly employed thereon. 'The emissary,' says Sir R. C. Hoare, 'commences in a plain near the lake, traverses a mountain of solid rock, and pursues its course through the Campi Palentini to Capistrello, where it discharges itself into the Liris. The present emissary is far advanced into the lake, and considerably below the ordinary surface of the water.' At present the emissary is blocked up, except a portion of the exit near Capistrello, which has been so far cleared as to show the nature of the work. Fazio, a living Neapolitan engineer, has written a memoir on the subject, showing that the emissary might be easily repaired; and a company of land proprietors was formed, some years since, to recover, by drainage, the lands overflowed by the lake. The works for cleansing the emissary were, according to late accounts, in a state of progress, under the direction of an architect. A little to the north of the lake is the deserted village of Albi, on an eminence, probably the Alba Fucinensis of the Romans. From Avezzano, which is near the lake, the traveller may proceed northwards, through the valley of Cesolino to Tagliacozzo, built on the right side of a deep ravine. 'On ascending the hill,' says Sir R. C. Hoare, 'May 17, a dreary extent of rocky mountain expanded itself to my view, and the trees had not yet laid aside their wintry garb, but were just pushing forth their leaves.'

The mountains of the Abruzzi, though forming an essential part of the Apennine chain, and therefore running, generally, from north-west to south-east, are extremely irregular. They send out smaller branches towards the coast of the Adriatic, forming beds for the numerous streams which flow into that gulf. In the centre they form several high ridges, sometimes diverging from, and sometimes parallel to, each other; the valley of Aquila lies between Monte Corno and Monte Velino, and between the latter and a more southern ridge lies the basin of Celano. The valleys of the Abruzzi, to the west of the Lake Celano, are watered by the Liris, the Turano, and the Salto, which two last join the Velino. The real back-bone of the Apennines, by which we mean the line which divides the waters that flow eastward from those which run westward or southward, may be traced between the sources of the latter river and those of the Tronto, which flows into the Adriatic. Following it to the south, we find the sources of the Pescara, which also runs into the Adriatic; and we trace the main chain farther south, on the east side of the basin, which contains the Lake of Celano. The direction then winds round the south part of the lake, and afterwards runs to the head-waters of the Sangro, which flows in the same direction as the other two rivers. It then strikes direct east, separating Abruzzo from Campania and the province of Molise, and passing between Castel di Sangro and Isernia, joins Mounts Biferno and Matese south-east of the latter. The central Apennines, to the north and east of Lake Celano, contain the highest points in the whole range. Monte Velino is seen from the eminence of Albi to the north, raising its lofty head 8397 feet. Farther north, Monte Corno, the highest point of the Apennines, sometimes called the great rock of Italy (*il gran sasso d' Italia*), rises to the height of 9521 feet, and its summit is covered with snow, sometimes perhaps through the whole year. Vegetation, however, ceases only 600 feet below its highest point. Another lofty mountain, called Monte Majella, projects out of the main ridge between the valley of the Pescara and that of the Sangro, to the north-east of Sulmona, its highest summit being 8500 feet. This is an extinct volcano. The mountains of Abruzzo are among the finest in the whole Apennine range. They are less naked than those further north, and they present groups of a bolder and more romantic appearance. Spreading over a vast extent of country, 50 or 60 miles in breadth, they enclose delightful valleys, towns, and a numerous population within their various ridges: the whole province of Aquila is, in fact, encircled by them. These mountains are calcareous, like the great mass of the Apennines. M. Orsini, a naturalist from Ascoli, observed on the sides of Monte Corno, masses of gneiss laid bare by the waters which had carried off the crust of alpine lime, of which the external cliffs are formed. A party of botanists from Naples visited these mountains in the summer of 1829, they ascended Mounts Velino, Corno, Majella, and other high pinnacles. M. Tenora, one of the party, published an account of their observations. They found Mount Velino rich in rare plants, and the view from its summit magnificent. They suffered much from thirst, as they met with no springs on this mountain.

The brief description of Antinori, an Italian writer, is, on the whole, correct:—'There are, in many places, rough and inaccessible mountains always covered with snow, wild forests, pleasant woods, agreeable pastures, clear fountains, deep lakes, and many rivers of every size, which run from the one, or the other side, to seek the one or the other sea of Italy.'

The natives of the highlands of Abruzzo are chiefly employed in the rearing and tending of sheep, numerous flocks of which, after feeding on the mountain pastures during summer, migrate to the plains of Puglia at the approach of winter. The shepherds are generally accompanied by their wives and children in these yearly migrations to and from the mountains, and by their large white dogs, which are very fierce to strangers. The sheep's milk is used to make cheese, the wool is an important article of trade, and the skins are exported in great quantities to the Levant. The shepherds also are clothed in them, and wear sandals of untanned leather, fastened with small cords, round the leg: they are a quiet, frugal, and honest race. The breed of merino sheep has lately been introduced into the Abruzzi near Sulmona and Valloscura, wool being now in great demand for the fast-increasing manufactures of the kingdom. The labourers and farmers in the Abruzzi are mostly poor, few of the latter being proprietors; and although the feudal duties have been long since abolished, yet the land-tax is very oppressive, amounting in many instances to 30 per cent. on the estimated income of the land. Improvements in agriculture, and especially in the method of manuring the land, are little known. Numerous herds of swine are fed in the extensive oak forests that cover the mountain sides; and the hams and sausages of Abruzzo are in great request. Lamb and mutton are also of excellent quality.

The woods of the Abruzzi have been sadly laid waste during the last thirty years: fine timber trees, oaks and beeches, have been wantonly cut down; and the mountains having thus been laid bare, the rain and melted snow, meeting with no obstacle, have washed off the soil, and carried devastation into the fields below. A want of fuel has been felt in many places, which is a serious evil in the high regions that are exposed to eight months' winter; but to remedy this inconvenience, the government has now relieved the new plantations from taxation. The mountain fastnesses are inhabited by bears, wolves, and wild boars. These provinces are but little frequented by travellers. Sir R. C. Hoare, who visited the Lake Celano, says of this country:—'The province of Abruzzo, unfrequented by the generality of travellers, and unknown even to the inhabitants of the neighbouring districts, like Sicily, has been represented as a country uncivilized with regard to society, infested by robbers, inaccessible from mountains, and fitter for the residence of wild beasts than of rational beings. But I must here repeat, with gratitude, that, in these romantic, unfrequented tracts, we met with that genuine and cordial hospitality which is too seldom to be found in more favoured and more populous countries.'

The natives of Abruzzo are generally tall, robust, and healthy; their countenances are mild, and their manner quiet and civil; they are intelligent, industrious, and brave, and furnish the best soldiers in the Neapolitan service. They are hospitable; even the poor peasant will cheerfully receive the stranger into his cabin, and offer him a share of his scanty pittance. Their cabins, however, are often miserable, smoky, and filthy; the pig and the donkey share them with the family. The chief article of food consists of Indian corn flour boiled in water or skimmed milk; wheaten bread is a luxury; wine, however, is drank generally, being imported from the neighbouring districts. The women work in the fields as hard as the men. Thousands of peasants leave their mountains in the autumn, to go and work in the vast farms of the Roman lowlands, and return in the beginning of summer; whilst others proceed at that period to reap the harvest in the unwholesome plains, and to brave the malaria fever, which makes great havoc among them. Many of the Abruzzi shepherds may be seen in December perambulating the streets of Naples and of Rome, with their bagpipes, with which they go playing from house to house, in honour of the approaching Christmas festivities. Others come to live altogether at Naples, where they employ themselves as porters, grooms, and in other hard service; and they bear a general reputation for honesty above the natives of the other provinces of the kingdom. Indeed, a traveller may ramble over the wild mountains and glens of Abruzzo in greater safety than through the fertile plains of Campania. The natives of Abruzzo speak better Italian than those of the other provinces of the kingdom; in fact, they cannot be said to speak a dialect; their language, especially at Aquila, and round the Lake of Celano, resembles that of their neighbours of the Roman States. The young men, who can afford it, repair to Rome and Naples to follow their studies, and generally distinguish themselves by their assiduity and regularity.

The lower parts of the Abruzzi have a productive soil, and export a considerable amount of grain, oil, and almonds: they also produce some cotton. In some parts of the Abruzzi we find the system of terrace husbandry, which has converted the arid hills of Tuscany into productive gardens. Of the three provinces that of Aquila is the most mountainous and the poorest; the city of Aquila, however, is considered as one of the principal provincial towns in the kingdom, and contains many wealthy families. Its territory produces excellent saffron. The province of Teramo is fruitful in rice and corn. That of Chieti is the most fertile of all, and its wines are much esteemed. The olive grows in both the latter provinces. The city of Chieti, the finest in all Abruzzo, is well built, in a delightful situation, ten miles from the sea, has manufactures of silks and woollens, a lyceum, a theatre, several literary societies, and is a place of considerable wealth and luxury. Abruzzo is, upon the whole, a very important as well as very interesting division of the Neapolitan States, of which it constitutes the chief defence on the land side. During the numerous invasions and civil wars of that kingdom, it has been often the scene of protracted contests. It was at Tagliacozzo that the unfortunate Corradino was defeated by Charles of Anjou. It was likewise in the Abruzzi that Alfonso of Aragon recruited his party and maintained himself for years, until at last he was enabled to drive away René, the last of the Anjou kings, from the throne of Naples. The possession of the Abruzzi has always tended materially to decide the fate of Naples. In 1799 the mountaineers strenuously opposed the French troops, and assisted in the recovery of the kingdom.

Albanian and Greek colonies are found scattered about the Abruzzi, as well as in the other eastern provinces of the kingdom of Naples. They occupy whole villages with the districts around them, and form so many distinct populations in the midst of the indigenous inhabitants, preserving the manners, the language, and partially the dress, of their ancestors. These colonies date from different periods: the Albanian or Epirote emigration took place in the fifteenth century, in the time of Scanderbeg and his son John Castriot. The town of Ururi, on the borders of the nearer Abruzzo and Puglia, is an Albanian colony. The Greek emigrants from the Morea came away when that peninsula was lost to the Venetians in the last century; the town of Villa Badessa, in the farther Abruzzo, was peopled by them. These people associate but little with the surrounding population, who look upon them as semi-barbarous strangers; they are, however, acknowledged to be industrious, brave, tenacious of their lands and privileges, honest, jealous of the honour of their women, and strongly united among themselves. The whole number of their villages or colonies throughout the kingdom is about fifty, and their whole population is estimated at 52,000.

Three roads lead into the Abruzzi from the Roman States, one, which is a post-road, on the Adriatic side, proceeds from Ascoli to Teramo, and thence to Penna and Sulmona, where it joins the high-road to Naples. The second is a mountain-road, leading from Rieti to Civita Ducale, and by the pass of Antrodoco to Aquila. The third, also a mountain pass, leads direct from Rome by Tivoli and Vicovaro to Tagliacozzo, and the banks of the Lake of Celano. The only carriage-road from Naples to Abruzzo leads by Venafro to Isernia, in the province of Molise, the ancient Samnium; thence over the central Apennines to Castel di Sangro, which is the first town in Abruzzo, and further over a high wild mountainous region to Sulmona and Popoli on the Pescara, where the road divides, one branch to the left leading to Aquila, and the other to Chieti.—[*Zannoni's Map of the Kingdom of Naples—Balbi's Geography—Tenore, viaggio in Abruzzo,* Naples, 1830—*Classical Tour by Sir R. C. Hoare,* 4to. 1819.]

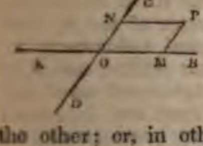
ABSCESS, (from a Latin word, *Abscedo*, implying separation,) is so called, because parts which were in contact have become separated. An abscess consists of a collection of the matter termed pus, in some tissue, or organ of the body. Purulent matter, or pus, is formed out of the blood by the process termed secretion. Of the intimate nature of this process, as of that of all the other secretions, we are ignorant. What is certain is, that the formation of pus is never a healthy process, and never an original disease. It is always the result of another disease,—namely, inflammation; or, if there be any exceptions, they are so few that they need not be taken into account here. The process consequent on an inflammation, by which pus is secreted, is termed the process of Suppuration, of which we shall speak further under the article INFLAMMATION.

The purulent matter constituting an abscess, properly so called, is always confined within a definite space: the means by which it is confined vary. Sometimes the purulent matter is effused into the substance of an organ; in this case some portion of that part of the blood which is called *fibrin*, or coagulable lymph, is effused with it; this fibrin coagulates into a firm solid, encloses the pus, and so prevents its diffusion. Sometimes the effused fibrin, or coagulable lymph, becomes organized; in this case it forms a new membrane, which is called an *adventitious* membrane, and the pus is completely enclosed in this new membrane as in a bag, or shut sac or *cyst*: an abscess of this kind is called an *encysted* abscess, and the internal surface of this cyst is always endowed with the properties both of absorption and of secretion; for large collections of matter, enclosed in bags of this kind, occasionally disappear without any external opening; and on the other hand, when such a bag has been completely emptied of its contents, it is sometimes rapidly refilled with pus. When an opening is formed in an abscess, and purulent matter continues to be discharged from it, it loses the name of abscess, and takes that of ulcer.

Purulent matter is poured out from the blood in other modes, and forms other collections of pus; but these latter collections are never called abscesses. Sometimes, for example, the pus, as it is secreted from the blood, is diffused through the substance of the inflamed organ. This is the case especially with the lung during the progress of inflammation. This diffusion of purulent matter through the substance of an inflamed organ is termed INFILTRATION; and, instead of containing an abscess, the organ is said to have pus infiltrated through it.

Again, collections of purulent matter are often formed in natural cavities. The cavity of the thorax, for example, is lined with a serous membrane called the PLEURA, and the cavity of the abdomen with a serous membrane called the PERITONEUM. In consequence of the inflammation of these membranes, pus is often poured out on their surface, and accordingly large quantities of it are found accumulated in those cavities: but in this case it is merely said that pus is contained in the cavity of the thorax or in that of the abdomen; we never say that those cavities form abscesses.

There are few tissues of the body, and still fewer organs, in which abscesses may not form. They are found in the brain, the lungs, the heart, the liver, the spleen, the uterus, the ovaria, the cellular membrane, and the joints. In some of these organs the disease is highly dangerous, in others certainly fatal, in others comparatively unimportant. In whatever organ an abscess may have its seat, the affection will give rise to a peculiar and definite train of symptoms dependant on the peculiar structure and function of the organ affected; but the symptoms which attend the formation of abscesses, and the phenomena which accompany and denote the successive stages of their progress, the different modes in which they terminate, their diagnostic or distinctive signs, and their treatment, all these topics belong properly to the subject of suppuration, and will be treated of under the article INFLAMMATION.



ABSCISSA, or LINEA ABSCISSA, a line cut off, is a mathematical term, used as follows: If any two right lines AB, CD, be given, meeting in O, the position of any point, P, in the plane of those lines, is known when we know (I.) within which of the four angles, BOC, COA, AOD, DOB, it lies, and (II.) what is its distance from each line, measured on a line parallel to the other; or, in other words, what are the sides of the parallelogram OMPN. Either of these sides being called the *abscissa*, the other is called the *ordinate*; both are called *co-ordinates*; the straight lines, AB and CD, are called the *axes*, and O is called the *origin*. It is customary to denote the lengths of the abscissa and ordinates by the letters x and y respectively. Thus, OM being the abscissa of the point P, PM is its ordinate. All points in the line PM have the same abscissa; all those in PN the same ordinate.—See EQUATION, CURVE, POSITIVE, NEGATIVE.

ABSENTEE. This is a term applied, generally by way of reproach, to that class of capitalists who, deriving their income from one country, reside in another country, in which they expend their property. The name has been adopted in political economy; and it is with reference to the principles of that science that we here propose to state some of the more material points in a controverted question of great interest,—namely, whether the consumption of absentees is really an evil to the particular country from which they derive their revenues. It is of the more importance that a right judgment should be formed upon this matter, as there is a decided tendency in the progress of social intercourse to loosen the ties which formerly bound an individual or a family to one particular spot. From the improvement of roads, and the rapidity and certainty of steam navigation, Dublin is now as near, in point of time, to London, as Bath was half a century ago; and the distance between England and every part of the continent is in the same way daily diminishing. With the conviction, therefore, that the inducements to absenteeism, whether from Ireland to England, or from England to the Continent, are constantly increasing, it would be satisfactory to find that a theory which asserts that absenteeism is not wholly an evil, has some foundation in reason and experience.

The expenditure of a landed proprietor resident upon his estate, calls, or appears to call, into action, the industry of a number of labourers, domestics, artisans, and tradesmen. If the landlord remove to another part of the same country, the labourers remain; the domestic servants probably remove with him; but the artisans and tradesmen whom he formerly employed lose that encouragement which they once derived in the exchange of their skill or commodities for a portion of the landlord's capital. It never occurs to those who observe, and perhaps deplore these changes, that the landlord ought to be prevented spending his money in what part of his own country he pleases. They conclude, reasonably enough, that there is only a fresh distribution of the landlord's revenues; and that new tradesmen and mechanics have obtained the custom which the old ones, through uncontrollable circumstances, have lost. But let the same landlord go to reside in a foreign country—let the Englishman go to France or Italy, or the Irishman to England,—and it is immediately asserted that the amount of revenue which he spends in the foreign country is so much clear loss to the country from which he derives his property, and so much encouragement withdrawn from its industry; and that he ought, therefore, to be compelled to stay at home, instead of draining his native land for the support of foreign rivals. Some of the more eminent of our political economists maintain that this is a popular delusion, and that, in point of fact, the revenue spent by the landlord in a foreign country has precisely the same effect upon the industry of his own country, as if his consumption took place at home, for that, in either case, it is unproductive consumption. We will endeavour to state their arguments as briefly as we can.

Let us suppose a landowner deriving an income of 1000*l.* a-year from an estate in one of our agricultural counties. We will leave out of the consideration whether he resides or not upon that estate;—whether he lives in the hall of his fathers, employing the moral influences of property for the amelioration of the lot of his poorer neighbours, or lets that hall, as well as his paternal acres, to one or more farmers. The landowner resides himself in London, or Brighton, or Cheltenham, or any other place congenial to his taste. With his rents he probably purchases many articles of foreign production, which have been exchanged for the productions of our own country. No one questions his right to purchase these foreign productions; for there are few people now who do not understand that if we did not take from foreigners the goods which they can produce cheaper and better than we can, we should not send to foreigners the goods which we can produce cheaper and better than they can. If we did not take wines from the continental nations, for instance, we should not send to the continental nations our cottons and hardware; and the same principle applies to all the countries of the earth with which we have commercial intercourse. The landlord, therefore, by consuming the foreign wines encourages our own manufactures of cotton and hardware, as much as if, drinking no foreign wine at all, he applied the money so saved to the direct purchases of cotton and hardware at home. But he even bestows a greater encouragement upon native industry, by consuming wine which has been exchanged for cotton and hardware, than if he abstained from drinking the wine: for he doubtless himself uses as much cotton and hardware as he wants, as well as the wine; and by using the wine he enables other people in Europe to use the cotton and hardware, who would otherwise have gone without it. For all that he consumes of foreign produce, some English produce has been sent in exchange. Whatever may be the difference between the government accounts of exports and imports (than which nothing can be more fallacious), there is a real balance between the goods we send away and the goods we receive; and thus the intrinsic value of all foreign trade is this,—that it opens a larger store of commodities to the consumers, whilst it developes a wider field of industry for the producers. (See EXPORTS.) There used to be a notion, which, for many years, governed the decisions of our legislators, that unless we sent away to foreigners a great many more goods than we received from them, or, in other words, unless our exports were much greater than our imports, the balance of trade was against us. (See BALANCE OF TRADE.) This notion was founded upon the belief, that if we sent away a greater amount of goods than those we received in exchange, we should be paid the difference in bullion; and that the nation would be rich, not in the proportion in which it was industrious at home, and in which its industry obtained foreign products in exchange for native products, but as it got a surplus of gold, year by year, through its foreign trade. Now, in point of fact, no such surplus ever did accrue, or ever could have accrued; for the commercial transactions between one country and another are nothing but a series of exchanges or barter, and gold is only the standard by which those exchanges are regulated. (See Bullion.) We shall see how these considerations bear upon the relations of the English landlord to his native country when he becomes an absentee.

When the landlord, whose case we have supposed, resided upon his estate, he probably received his rental direct from his tenants. That rental was, in truth, the landlord's share of as many quarters of corn, as many head of oxen and sheep, as many fleeces of wool, as many fowls, as many pounds of butter, and so forth, as the estate produced. Three or four centuries ago the landlord's share was paid in kind: for the convenience of all parties, it is now paid in money, or, in other words, the tenant sells the landlord's share, as well as his own share, and pays over the amount of his share to the landlord, in a money-rent, instead of in produce. When the landlord removes to a distant part of the country, this arrangement of modern times becomes doubly convenient. The rental is then collected by a steward, and is probably paid into the hands of a country banker, who draws a bill of exchange in favour of the landlord. By this process, the produce of the land may be most advantageously sold; and the landlord receives the amount of his share at his own door, without even the risk of sending money from one part of the kingdom to another. If it were not so, the servants of a great landed proprietor residing in London might announce to their master,—

> 'A hundred oxen at your levee roar.'

If the landlord becomes an absentee, the process of remitting his rental assumes a more complicated shape. We will suppose that his inclination leads him to settle in the Netherlands. His means of living there depend upon the punctual transmission of the value of his share of the corn, cattle, and other produce growing upon his estate in England. To make the remittance in bullion would not only be expensive, but unsafe: and, indeed, remittances in bullion can never be made to any considerable extent (such as the demands of absentees would require) from one country to another; for these large remittances would produce a scarcity of money at home, and then the bullion being raised in value, its remittance would necessarily cease. (See Course of Exchange.) Although the expenses of our armies in the Peninsula, in 1812-13, amounted to nearly 32,000,000*l.*, the remittances in coin were little more than 3,000,000*l.* Nearly all foreign remittances are carried on by bills of exchange. The operation of a bill of exchange, in connexion with our absentee landlord, would be this. He is a consumer now, in great part, of foreign produce; he probably requires many articles of English produce, through the effect of habit; but whether or no, there must be an export of English goods to the amount of the foreign goods he consumes, otherwise his remittances could not be made to him. He draws a bill upon England, which he pays, through a banker, to a merchant at Antwerp. This bill represents his share of the corn and cattle upon his farm; but the merchant at Antwerp, who does not want corn and cattle, transmits it to a merchant at London, in payment for cotton goods and hardware, which he does want. Or there may be another process. The agent, in England, of the absentee landlord, may procure a bill upon the merchant at Antwerp, which he transmits to the English landlord; and the merchant at Antwerp, recognising in that bill the representation of a debt which he has incurred to England, hands over the proceeds to the bearer of the bill. In either case the bill represents the value of English commodities exported to foreigners. We thus perceive how the consumption of an English resident in a foreign state, out of a capital derived from England, produces, in principle, the same indirect effects upon English industry, as his partial or entire consumption of foreign goods in England. His consumption of foreign goods abroad is equivalent to an importation of foreign goods into England; and that consumption produces a correspondent exportation of English goods to the foreigner. Let it not be said that England sends out a thousand pounds' worth of her exports in consequence of the absentee's residence abroad, and gets nothing in return. She would have had to pay a thousand pounds to the landlord wherever he resided; and the only question is, whether she pays the amount less advantageously for the national welfare to the absentee, than to the resident at home. The political economists, whose opinions we have endeavoured to exhibit, maintain that she does not. It is probable that a good deal of the difficulty which this question presents, has arisen from the circumstance, that the subtraction of a particular amount of expenditure from a particular district, is felt in the immediate locality as an evil; while the benefit which still remains to the whole country is not perceived, because it is universally diffused.

But it would be a widely-different question if the absentee landlord, who had been accustomed to expend a certain portion of his income in the improvement of his estate in England, were to suspend those improvements, and invest his surplus capital in undertakings in a foreign country. This the political economists, who have been most consistent in their opinions as to the effects of absentee consumption, never maintained: if they had, they would have confounded the great distinction between accumulation and consumption, upon which the very foundations of their science rest.—(See Accumulation.)—In many cases the smaller consumption of an absentee, in a country where the necessaries of life are cheap, enables him to accumulate with greater ease than he could at home; and this accumulation is, in nearly every case, invested at home. It is the same thing whether the absentee improves his own estate by the accumulation, or lends the amount of the capital so saved to other encouragers of industry at home. Nor could the political economists ever have intended, we apprehend, in maintaining, as a mere question of wealth, that it was a matter of indifference where an income was spent, to put out of view the moral advantages which arise out of a just and rational course of individual expenditure. The absurd notion, which even the philosopher Montesquieu fell into in the last century, that if the rich did not spend liberally the poor would die of hunger, is fast passing away; because it is evident that whenever a portion of this particular consumption is suspended, there is an accumulation of capital, which is sure to set profitable industry to work in some way or other. But at the same time, without attaching undue importance to the influence of a rich man's consumption, it is undeniable that it may be so directed as to call into existence profitable instead of worthless industry, and thus to become a beneficent instrument of civilization to all those within the sphere of its power. In the ruder stages of society such an influence stands in the place of liberal endowments for education; and prepares the way for that general spread of intelligence which probably requires higher and more permanent incentives towards perfection than any individual influence, however great. When a country possesses zealous as well as numerous teachers of religious truths, ample establishments for public instruction, a wholesome and widely-spread literature, and ready and cheap communication, the moral influences of a benevolent resident landlord will be scarcely more felt than the example of any other wise and good man. But in a country far short of this high state of civilization, the possessors of property have duties to discharge which cannot easily be deputed, and certainly not safely neglected. It is this which makes the question of absentees, as regards Ireland, so difficult to treat upon principles of political economy alone. The absence of the principal landholders of that country must, morally considered, be a very serious evil; but it is an evil not without mitigation. The necessity for a large exportation of the products of the industry of Ireland to support her absentee expenditure, calls into action a great quantity of profitable labour, to meet the wants of the English market in the most beneficial manner to the producer. The exportation of eggs from Dublin to Liverpool alone amounts, at one halfpenny each, to more than 50,000*l.* a year, and that of poultry is equally considerable. This impulse to the industry of the small tenantry, by exchange with England, will probably, in time, do as much as the residence of the landlords of Ireland could do to raise her peasants from the condition of miserable cottiers to that of independent yeomen. It will unquestionably do more than the presence of a debauched and even careless landlord, such as Miss Edgeworth has described in *Castle Rackrent*, who was wont to swallow up the few crumbs which his larger exactions left his dependents, in the shape of *duty* eggs and *duty* fowls.

[See M'Culloch's Evidence before the Select Committee on the State of Ireland, 1825, Fourth Report, pp. 813-14-15; also his Evidence before the Select Committee on the State of the Poor in Ireland, 1830, p. 592, &c.—Leslie Foster's *Essay upon Commercial Exchange*, 1804, quoted in the last-mentioned Report, p. 597—Say, *Cours Complet d'Economie Politique*, tom. v. chap. 6—Chalmers on *Political Economy*, p. 200, 1832—*Quarterly Review*, vol. xxxiii. p. 459, for an hostile examination of Mr. M'Culloch's opinions.]

ABSOLUTION, a religious ceremony in use in different Christian communities, by which the priest declares an individual, on repentance and submission to the requisite penance, to be absolved either from his sin, or from the ecclesiastical punishment or deprivation to which it had rendered him liable. It is contended by many theological writers, that down to the twelfth century the priest in this act only used the words 'May God, or may Christ, absolve thee;' thus refraining from claiming any authority to remit the sin himself. Since then, however, the formula used in the Roman Catholic church has been *Ego te absolvo a peccatis tuis* (I absolve thee from thy sins), accompanied with the sign of the cross. The Council of Trent has expressly condemned the doctrine that the priest has not power of himself to absolve from the guilt of sin. (Session xiv. Canon 4.) The Church of England also holds, as may be seen in the Order for the Visitation of the Sick, that power has been left to the church to absolve repentant sinners; and the words which the minister uses in performing the ceremony are nearly the same with those employed in the Catholic communion, 'I absolve thee from all thy sins.' It has, however, been maintained by some that the absolution thus bestowed is only declaratory, while that pronounced by the Catholic priest is professed to be absolute, and to proceed solely from himself. In the Greek church the formula is merely declaratory; that is to say, it is of the nature of a prayer to heaven that the sins of the penitent person may not be visited with their due punishment. It is so also in the Protestant Church of Scotland; and there the term absolution is commonly used to denote simply the declaration of the Kirk-Session or other judicatory, expressed by the mouth of its president, that the party is released from the ecclesiastical interdict to which his delinquency had subjected him.

ABSORPTION, from *absorbeo*, to suck up. The function of absorption is one of the most curious and important of the animal economy. The matter of which the living body is composed is in a state of continual change: old particles are every moment taken from their situation and carried out of the system; new particles are every moment conveyed to the place occupied by the old and deposited in their room. The constituent matter of the living body is, therefore, never exactly the same in two successive moments. This change of the constituent matter of the living body is effected by the process termed absorption, and the agents by which this process is carried on are the absorbent vessels. The absorbent vessels possess a peculiar structure essentially different from that of arteries, veins, or any other vessels of the body, and their action likewise is altogether peculiar. The absorbent vessels consist of two distinct sets. The first arise from the alimentary canal, and more especially from the small intestines. They absorb the digested aliment, and are the instruments by which the new particles of matter, which are necessary to supply the loss occasioned by the removal of the old, are carried into the system. This new matter, which is termed CHYLE, is of a white colour, very much resembling milk; and these vessels, when full of it, have the appearance of minute tubes distended with a milky fluid; hence they are called LACTEAL VESSELS, (that is, milk-vessels.) The other set arise from every part of the body,—from the whole of its external surface,—from the whole of its internal surface,—from every one of its tissues,—from every one of its organs,—so that the point of the finest needle can touch no part of the body without coming into contact with a branch of this system of vessels. At every point of the body these vessels are always at work, taking up and carrying away the old and worn-out particles. But, further, those which are spread out on the external skin, and those, also, which are spread out on the internal skin, on the membrane which lines the air passages, for example, and on that which lines the passage to the stomach, are capable of taking up many foreign substances which may come into contact with them, and often powerfully affect the system by introducing into it these foreign bodies. Whatever be the nature of the substance contained in this second set of vessels, and from whatever source it be derived, it is always without colour when received into the vessel, and perfectly transparent and pellucid; on this account it is termed *Lymph*, and these vessels are, therefore, called LYMPHATICS. The LACTEALS then contain new matter derived from the digested aliment: the LYMPHATICS contain the old and worn-out particles of the system, together with whatever substances may have been taken into it from the surfaces of the body. The structure and the course of these vessels, and the agencies by which they receive and circulate their contents, will be treated of under the terms LACTEAL and LYMPHATIC VESSELS.

Of the real existence and the active operation of the function of absorption there is indubitable proof.

1. In the first place, in certain states of the system, there is a wasting of the flesh, a dissipation of the solids, a diminution of the weight of the body; under other circumstances, while the general system remains unaffected, particular parts of the body diminish in size, or even disappear altogether. These phenomena are not dependent on any external influence, and cannot be referred to the action of any physical agent. They can be accounted for only on the supposition that processes are constantly going on within the body, which remove from the system both the solid and the fluid parts of which it is composed.

2. In the second place, if fluids be injected from without into the internal cavities, or if they be effused in the progress of disease, these fluids disappear sometimes spontaneously, and still more often under the influence of particular medicinal substances. An opening was made into the cavity of the abdomen of a living animal; three quarts of water were injected and secured; in six hours after this operation the animal was killed, and the state of the abdomen was examined; not more than four ounces of the water remained. Oftentimes, after digitalis or fox-glove has been taken some days in succession, large collections of water in the different cavities of the body disappear in the course of a few hours.

3. In the third place, various substances, when placed in contact with a living surface, produce the same effects upon the system as when received into the stomach, or injected into the veins. Arsenic, when applied to an external wound, will sometimes affect the system as rapidly and as powerfully as when introduced into the stomach. A strong infusion of tobacco, when applied to the pit of the stomach, will occasion vomiting, when injected into the rectum will produce almost immediate fainting, and unless care be taken this fainting will end in death. These phenomena can be accounted for only by supposing that the substances in question are really conveyed into the system.

Many facts testify the action of cutaneous or external absorption. It is proved by direct experiment, that the human hand is capable of imbibing, in a quarter of an hour, an ounce and a half of warm water, which, for the whole body, is at the rate of six or seven pounds per hour. An interesting narrative is on record of a ship's crew who were exposed at sea for several days in an open boat; they had consumed all their water; they had no fluid of any kind which they could drink; they soon began to suffer from thirst; the feeling at length became intolerable, and the drinking of sea-water was found only to increase its intensity. When nearly exhausted, they were exposed, during several hours, to a heavy shower of rain. As soon as their clothes became thoroughly wet their thirst began to abate, and before the rain had ceased their thirst was gone. They did not fail to profit by this experience. From this time each man, as soon as he began to feel thirsty, dipped his shirt in the sea-water and wore it next his skin, which had invariably the effect of removing his thirst, the absorbents taking up the particles of water, but rejecting the saline matter dissolved in it.

The function of absorption explains many phenomena connected with health, with disease, and with the action of remedies. The agents which produce disease, and especially the widely-extended and powerful causes of fever,—namely, animal and vegetable matter in a state of decomposition; these, together with the effluvia of marshes, exhalations from the animal body itself, and perhaps other noxious gases diffused in the atmosphere, afford striking illustrations of its operation. An exposure but for a few minutes to an atmosphere loaded with marsh effluvia, of an intensely noxious nature, may produce a protracted ague, or even instantaneous death. Even a few inspirations of an atmosphere, rendered foul by exhalations from the human body, may produce, in a person previously healthy immediate nausea and vomiting, followed by severe and pernicious fever. A person labouring under small-pox may contaminate the air of a room to such a degree that a healthy person, breathing this air but for a short space of time, may become affected with the disease, although the infected may never have come into actual contact with the infecting person. In all these cases a poison is diffused through the atmosphere, which comes into contact with the surfaces of the body, and so affects the system through the medium of absorption. The free dilution of this poison with pure air will destroy, or render innoxious, these malignant agents; hence, persons who are under the necessity of remaining constantly in the chambers of the sick may remain there with perfect impunity, if these chambers are frequently and thoroughly ventilated; while, if ventilation be neglected, or imperfectly performed, not only is the disease of the patient aggravated, and perhaps by this cause alone rendered mortal, but his nurse also is sure to suffer; hence the value of this further fact, which cannot be too constantly borne in mind, that these noxious agents always affect the system exactly in proportion to its want of energy. Exposure to a powerful noxious agent,—when the stomach is empty,—when the body is exhausted by fatigue,—when the mind is depressed and desponding,—will occasion a mortal disease; exposure to this very same agent, when the body is well nourished,—when the functions are carried on with vigor,—when the mind is cheerful and confident,—will be attended with no appreciable effect. There is no kind or degree of sickness with which a family or an individual can be affected, in the management of which the knowledge of facts of this kind may not afford useful suggestions; but this knowledge is of paramount importance when malignant and mortal epidemics attack a village, a city, a district, or a nation.

Nor is there less practical utility in attending to the action of absorption in relation to noxious agents which are generated within the body itself. When secretion is vitiated, and the morbid matter is absorbed by the lymphatics,—when digestion is imperfect, and unwholesome chyle is absorbed by the lacteals,—when the excretory portion of the alimentary canal is torpid, and the fæcal matter which ought to be carried out of the system is retained there and in part absorbed,—in such cases, the sensible qualities of the perspiration, the odour of the breath, the foul state of the skin, the loss of strength, the irritable and feverish condition of body and mind sufficiently declare the disorder of the system. Considerations such as these show the value of pure air, simple and easily digested food, moderate and regular exercise, purgative medicines, and remedies of the class termed alterative. By alterative remedies we mean medicinal substances that are absorbed from the surface of the alimentary canal, that enter the current of the circulation, that are conveyed by this channel to secreting organs, and that, by their influence over the actions of these organs, effect a salutary change in the general functions of the body.

ABSTINENCE, from *abstineo*, to abstain. The term abstinence signifies a total, or an excessive privation of food. It has been shown (see Absorption) that the constituent matter of the body is in a state of continual change,—that old particles are constantly taken up and carried out of the system, while new particles are as regularly deposited in their room to repair the loss. The source of these new particles is the aliment or food; but a second office is performed by the aliment scarcely less important than that of furnishing new matter for the renovation of the system. All the organs of the body are excited to the performance of their functions by certain external agents, which are called stimulants; such as air, water, heat, and so on; but of these stimulants the aliment is among the most indispensable and the most powerful. Upon the quantity and quality of the aliment depend the quantity and quality of the blood, and upon the quantity and quality of the blood depends in a great measure the energy of all the functions of all the organs. Any material change in the diet must necessarily produce a powerful impression on the system. Life can be maintained but for a short period under the total privation of food, while the excessive privation of it produces effects upon the system which have not been often observed with accuracy, but which are remarkably uniform, and highly curious and instructive. Opportunities occasionally occur of noting those effects with correctness and completeness, when, for example, the passage to the stomach is closed up by disease; or when, owing to an unsound state of mind, the individual refuses to take nourishment.

During the first two or three days after the total abstinence from food, in a person previously in sound health, the suffering from hunger is generally severe. The thirst is also at times distressing, but thirst is not constantly attendant. The pulse during this period remains natural, and so does the temperature of the body. All the evacuations are scanty, and take place at distant intervals. After the first two or three days the wasting of the body becomes visible, the fresh colour characteristic of health disappears, and the features and the limbs, instead of being plump and round, are sunk and collapsed. The loss of weight, which increases rapidly, is appreciable, and the progress of the emaciation is striking. The physical debility increases in exact proportion with the emaciation: and the mind becomes weak, confused, wandering, irritable, and at length almost deprived of reason. All this time there is little or no pain from hunger or thirst, or these uneasy sensations return only at intervals, and are seldom acute and never lasting. The pulse at this stage may be a little quickened; it is certainly easily excited; and in like manner the heat, which seldom sinks below the natural standard, is readily parted with,—so that a slight change of the temperature of a room is felt acutely, and produces very uneasy sensations, a fact which demonstrates to the physician the feebleness with which the functions are carried on, no less clearly than the physical debility itself. The most remarkable and curious phenomena which next supervene are those connected with the intellectual faculties. The loss of power to perceive accurately, and to connect the trains of thought, is followed by decided delirium, which is at first of a low muttering character, similar to that which takes place in the last stage of typhus fever; but this sometimes passes rapidly into furious and even maniacal delirium, requiring coercion just as a violent paroxysm of madness itself. Generally the delirium is preceded by a state of painful watchfulness and restlessness, it being impossible to procure sleep or quiet; and, finally, the skin becomes intensely hot, the pulse extremely rapid, the emaciation frightful, the debility so great that scarcely the slightest movement can be performed, and at length the individual sinks exhausted, commonly into a state of stupor amounting to that complete and profound insensibility which is technically called Coma.

This history of the progressive changes which take place in the system on the total abstraction of food, is illustrated in the most perfect manner, by two cases which fell under the notice of physicians capable of accurately observing and duly appreciating each successive event. Many wonderful stories are on record, of the truth of which there is no sufficient evidence; but the cases to which we refer were observed and recorded by men whose veracity is beyond question, and who were endowed with more than ordinary discrimination and judgment. The record on this account is invaluable, while in itself it is highly curious and instructive.

For the first case we are indebted to Dr. Currie, of Liverpool, the author of an admirable work on the application of cold as a remedy in certain cases of fever. In August, 1795, a gentleman of Yorkshire, aged sixty-six, applied to this physician for his assistance, on account of an obstruction in his swallowing food, with which he had been afflicted for ten or twelve months. At first the complaint was slight; it occurred only when he attempted to swallow dry and hard substances; it afterwards extended to solids of every kind; and, at the time he was first seen by his physician, although he was still able to pass down liquids, the quantity he could swallow was not sufficient for his nutrition, and he was considerably reduced. On the introduction of a bougee into the gullet, it passed about two inches easily, but then met with an obstruction which, by a moderate pressure, was overcome. It then passed easily seven or eight inches more, but, at the lower part of the tube towards its termination in the cardia, it met with a firm resistance, which no patience or skill could surmount. This obstruction proceeded from a schirrous tumour, which, gradually increasing at first, diminished the passage, and at length closed it wholly.

On the evening of the 17th of October a sudden increase of the obstruction came on, and from this time he was able to swallow only a table-spoonful of liquid at a time, and at long intervals. It was with difficulty that he got down seven or eight spoonsful of strong soup in the day, and this quantity gradually diminished. On the thirteenth day from this sudden increase of the obstruction, the passage appeared to be wholly closed.

The patient himself, to the last, was far from despairing of his recovery; and the affectionate friends around him, though they could not but see the issue of the case, yet desired that his life might be prolonged to the uttermost. The following plan was, therefore, adopted with this view. Every morning a clyster was administered, consisting of eight ounces of strong broth, made chiefly of the membranous parts of beef, these being considered the most nutritious, into which were rubbed two yolks of egg, and to which were added forty drops of laudanum. This was repeated in the afternoon, and again in the evening, previously to which, in the evening, he was placed up to the neck in a tepid bath, of which one-fourth was milk, and the rest water; the whole quantity amounting to twenty-four gallons. The temperature was fixed at 96°, to accommodate his sensations, and the time of immersion was gradually prolonged from forty-five minutes to an hour.

After a few days it was found that the retention of the rectum improved, so that the clysters were enlarged to ten ounces of broth, and three yolks of eggs each; to which were added eight ounces of white wine, and the laudanum, which was added to the evening clyster, was gradually increased from sixty to two hundred and fifty drops. Thus the whole of his nutriment for twenty-four hours consisted of thirty ounces of broth, twenty-four ounces of wine, nine yolks of eggs, and from 250 to 380 drops of laudanum, and administered by clyster; with what liquid might be supposed to be taken up in the bath by the absorbents of the surface of the body.

When in tolerable health at the commencement of his complaint, this gentleman, who was a tall man and naturally corpulent, weighed 240 lbs. Before the obstruction had become complete, imperfect nutrition had reduced him to the weight of 179 lbs. In twenty days, from the period of the sudden increase of the obstruction, he was reduced to 154 lbs.; on the twenty-fourth day he had lost 5 lbs. more; and at the period when his delirium commenced, that is on the thirty-second day from the night that he ceased to swallow, he weighed 138 lbs., having lost upwards of 100 lbs. of his original weight. He lived four days longer, that is, thirty-six days from the period when the obstruction was supposed to be complete; but, during these last four days, no nutriment, in any form or of any kind, was administered; for the rectum no longer retained the clysters, and the administration of the bath appeared, under these circumstances, to be wholly useless.

For a month after the total obstruction of the passage, the temperature and the pulse were natural; but on the thirty-second day the pulse became small and frequent; on the following day the eyes lost their common direction, the axis of each being turned towards the nose; he complained that he sometimes saw double, but the sensibility of the retina was increased rather than impaired; for, on the admission of the light of the window, he screamed out, though he had before been accustomed to this light. On the next day there was considerable incoherence of mind; this incoherence passed rapidly into delirium, during the prevalence of which there was a perpetual and indistinct muttering, with great restlessness and agitation; the skin and the extremities were sometimes of a burning heat, and sometimes clammy and cold; the pulse became feeble and irregular; the respiration, which hitherto had been singularly undisturbed, became laborious; and in ninety-six hours after the clysters and all other means of nutrition had been abandoned he ceased to breathe.

During the whole of this melancholy progress to inevitable death, this unfortunate gentleman complained very little of hunger: occasionally he expressed a wish that he could swallow, but not often nor anxiously; and, when questioned on the subject of his appetite, he always declared that he had no hunger which occasioned any uneasiness. The clysters evidently relieved the sense of hunger, and the opium they contained seemed to have a powerful share in producing this relief. It occasioned quiet and rest after each clyster, and allayed every kind of desire or appetite. Neither was he much disturbed with thirst. This sensation was, indeed, troublesome during the first days of his abstinence; but it abated, and, as he declared, was always removed by the tepid bath, in which he had the most grateful sensations. His spirits were uncommonly even, and his intellect perfectly sound. He occupied himself a good deal in his private concerns; and, as usual, interested himself in public affairs. In order to husband his strength he was confined a good deal to bed; but, till the last few days of his life, he dressed and undressed himself daily, and walked not only about his room, but through the house. His nights were quiet; his sleep sound, and apparently refreshing. Just before his delirium set in he had very lively dreams, which were all of a pleasant nature; and, in the last conversation he had with his physician, he told him he had had a very gay evening with two Yorkshire baronets whom he named; that they had pushed the bottle about freely; that many jokes had passed, at the recollection of which he laughed heartily, a thing uncommon with him; but it was observable that he was unable, longer than a moment or two, to distinguish this scene which had passed in sleep from a real occurrence; and this state of mind lapsed into delirium from which he never recovered. At this period he was so weak as to be scarcely able to turn himself in bed, to which he had been entirely confined several days, previously to his death.

The second case, which is no less interesting, occurred to Dr. Willan. A young man of a studious and melancholic turn of mind was affected with symptoms of indigestion, particularly with sharp pains in the stomach and a constant sensation of internal heat, for the relief of which he thought proper to begin a severe course of abstinence, hoping by this means, as he said, to remove his disagreeable complaints; but there was reason to believe that some mistaken notions on the subject of religion principally induced him to form this resolution. Having taken his purpose, he suddenly withdrew from business and the society of his friends, took lodgings in an obscure street, and entered upon his plan, which was to abstain from all solid food, and only to moisten his mouth from time to time with water slightly flavoured with the juice of an orange. After three days of abstinence the craving or desire for food, which was at first very troublesome, left him entirely; he then pursued his studies and meditations without further inconvenience; he used no manner of exercise; he slept very little, spending most of the night in writing; he consumed from half a pint to a pint of water daily, into which he squeezed the juice of the orange to give it an agreeable flavour. He persisted in this plan with firmness fifty-one days. During the succeeding ten days his strength failed rapidly; he was no longer able to rise from his bed: hitherto he had flattered himself that his support was preternatural, and indulged his imagination with the prospect of some great event which he expected would follow this extraordinary abstinence, but now that he found himself sinking to the grave his delusion vanished. About this time his friends discovered his retreat, and he was prevailed upon to assent to any plan that might be conducive to his recovery. He was seen by Dr. Willan on the sixty-first day of his fast: at that time he was emaciated to a most astonishing degree; the muscles of his face were entirely shrunk; his cheek bones stood prominent and distinct, affording a most ghastly appearance; the abdomen was concave, from the collapsed state of the intestines; the limbs were reduced to the greatest possible degree of tenuity, and the processes of their bones were easily distinguishable. His whole appearance suggested the idea of a skeleton prepared by drying the muscles upon it in their natural situations. His mind had become imbecile. He had undertaken during his confinement to copy the Bible in short-hand, and this work he had executed very neatly as far as the second book of Kings, with short arguments prefixed to each chapter. He showed his physician several improvements he had made in that kind of writing, particularly in the abbreviations. He had also, with great diligence, put together parallel passages, and traced particular subjects through the whole Scriptures, noting their application in different instances, and adding observations of his own. He appears at first to have proceeded in this undertaking with considerable ingenuity and judgment; but afterwards he became obscure, and seemed to be lost in endless confusion.

Unfortunately the treatment adopted was injudicious, the quantity of food allowed him being much too large; yet, for the first few days, he appeared to improve, regaining flesh and strength, and acquiring firmness and even cheerfulness of mind; but on the night of the fifth day he was sleepless and restless; on the morning of the sixth he began to lose his recollection, and before midnight he was quite frantic and unmanageable; at the same time his pulse was increased in frequency, with considerable heat of the skin, and tremors. During the following day he continued raving, and talking very incoherently, as he had done during the preceding night. He remained nearly in the same state, scarcely ever sleeping and taking very little nourishment, his pulse becoming daily smaller and feebler, and beating at length 120 strokes in a minute, and his emaciation still increasing, until the eleventh day from the period that he began to take food and medicine, and the seventy-second from the commencement of his abstinence, on which day he died, quite exhausted.

There is no authentic case on record in which the duration of the abstinence was as long as this, and both these cases taken together afford an excellent history of the disorder of the functions, and the exhaustion of the powers of life on the total and continued abstraction of food. The mind in the first case was naturally firm and strong; in the second it was supported by an enthusiasm amounting to insanity. When the mind is feeble, and especially when it is under the influence of fear, anxiety, despondency, or any other depressing cause, the duration of life is greatly abridged. It is instructive to observe the absence of severe suffering from hunger and thirst; the absence of all acrimony of the fluids; the absence of all violence and turbulence of mind until delirium set in, the precursor of death.

From the powerful influence of abstinence on the system, it is obviously capable of becoming a most energetic remedy in various diseases. When the mass of the fluids and solids of the body is too abundant, abstinence is capable of reducing them to almost any extent that can be required; and if the abstinence be judiciously commenced and conducted, not only is it unattended with any diminution of the strength or injury to the health, but it contributes to the improvement of both. Numerous instances are on record which place this fact beyond question. The case of Cornaro the Venetian nobleman, and that of the Essex miller, which afford evidence of this more complete than it would be easy to invent, are universally known. The body, whatever be its bulk or weight, provided the health be in other respects sound, may be reduced to almost any degree of thinness, and kept at that point by an appropriate regulation of diet and exercise. The physician, at his pleasure, can make no one fat, but he can make any one as thin as he chooses, frequently improving at the same time the health and vigour both of body and mind. Seldom is he called upon to put this art into practice, and seldomer than he ought does he insist upon carrying it into practice; but it is something to know that the resources of his art place this in his power.

In all acute diseases, such as the various forms of fever and inflammation, abstinence is a most powerful remedy, not only because the abstraction of nutriment diminishes the mass of the fluids and solids, (since the process of absorption goes on though the supply of new matter is stopped,) but also because it withdraws one of the main stimulants of the system, and consequently subdues the increased actions which accompany, and which for the most part constitute, acute diseases.

In some chronic maladies, especially in that large class which depend on what is termed plethora, that is, too great a quantity of solids and fluids, particularly in the plethoric state of the blood-vessels of the brain predisposing to and producing apoplexy, in some morbid affections of the stomach itself, in some derangements of the liver, and in several diseases of the heart, abstinence is an invaluable remedy. In other chronic diseases it is injurious, as in diseases of debility, in diseases which depend on irritation in contradistinction to those which depend on inflammation, and in various nervous maladies.

Abstinence is not equally well borne by all persons, nor at all times by the same person. By the corpulent and plethoric it may be endured longer, and carried farther, than by the thin and the spare: in the middle or mature age, it is less injurious than in infancy, youth, or extreme old age. A degree and duration of it, which are highly beneficial in a fever or an inflammation, would be fatal in the state of health.

It is curious, and it is highly important to bear in mind, that abstinence and excess produce symptoms so nearly alike, that it often requires the utmost care and sagacity on the part of the physician to distinguish the one case from the other; and as the one requires opposite remedies from the other, a mistake may be fatal, and must be injurious. A man, addicted to drunkenness, was cast into prison for theft, and reduced, at once, to a diet of bread and water. After the first week, a disorder of the intellectual faculties took place; his countenance became pale and expressive of languor, his flesh wasted, and his strength declined; his nights were sleepless; shortly afterwards there was delirium, which was mild at first, but subsequently furious. These symptoms might have been easily mistaken for those which denote inflammation of the brain; but the true nature of the affection was discriminated, and brandy was administered. Immediately the affection of the brain disappeared, and the flesh and strength returned.

Some time ago an alarming epidemic broke out in the Milbank Penitentiary, London. The prisoners confined in this prison were suddenly put upon a diet, from which animal food was almost entirely excluded. An ox's head, the meat of which weighs eight pounds, was made into soup for one hundred people, which allows one ounce and a quarter of meat to each person. The prisoners were at the same time subjected to a low degree of temperature, to considerable exertion, and were confined within the walls of a prison, situated in the midst of a marsh, which is below the level of the adjoining river. The consequences were, first, loss of colour, of flesh, and of strength; next, this simple debility of constitution was succeeded by various forms of disease—scurvy, dysentery, diarrhœa, low fever; and, lastly, affections of the brain and nervous system—namely, headache, vertigo, delirium, convulsions, apoplexy, and even mania. When bleeding was tried, the patients fainted after losing five, four, or even fewer ounces of blood. Abstinence will sometimes produce a train of symptoms exactly similar to those of the disease which it is employed to remove. Persistance in the abstinence will aggravate the malady, which will baffle every mode of treatment as long as the abstinence is persevered in; but which will disappear with surprising rapidity on the administration of a generous diet. This is especially the case with those affections of simple irritation which assume the appearance of inflammation, and which are attended with headache, noise in the ears, giddiness, restlessness, sleeplessness, and delirium. A professional man was seized with fever; rigid abstinence was enforced, not only during the continuance of the fever, but also during the stage of convalescence. Delirium, which had been present in the height of the fever, recurred in the convalescence. A physician of eminence in maniacal cases was consulted, who recommended him to be removed to a private asylum. Before this advice was carried into effect, another physician saw him: a different treatment and regimen, with a gradual increase of nourishment, were adopted; the patient was well in a few days, and within a fortnight returned to his professional avocations.

It is the common belief that abstinence is conducive to longevity, and many stories are on record which are conceived to establish the truth of this opinion. It is stated, for example, that the primitive Christians of the east, who retired from persecution into the deserts of Arabia and Egypt, lived healthfully and cheerfully on twelve ounces of bread per day, with mere water; that, with this diet, St. Anthony lived 105 years; James the Hermit, 104; Arsenius, tutor of the Emperor Arcadius, 120; St. Epiphanius, 115; Simeon the Stylite, 112; and Romauld, 120: to which are added many others. But we should remark that the evidence for these instances of longevity may not be quite satisfactory.

The quantity of food absolutely necessary to support the functions of life in vigor, is not known with any degree of exactness. Probably it varies with every constitution, and with every situation and circumstance that modify constitution. Provision is made in the economy for carrying out of the system superfluous nourishment, so that, within certain limits, more than is absolutely requisite is not injurious. Excess, without doubt, is always pernicious, and its direct tendency is to produce disease and to shorten life. For one person, however, who abridges the term of his life by excess, a hundred die prematurely from the want of a sufficient quantity of nutritious food. Persons who live in the bad air of a city require a larger quantity of food, and that of a more nutritious quality, than those who breathe the pure air of the country; and those who labour, physically or mentally, need a corresponding augmentation of food, in order to compensate the expenditure of the system. Persons in sound health, with a good constitution, having a tranquil mind, leading a quiet, contemplative life, without physical or mental labour, in a pure air, and taking regularly a good portion of sleep, may subsist a long time on very little food. And such seems to have been the condition of the Eastern Christian ascetics, whose abstinence and longevity have been so much celebrated. But, even under such circumstances, the processes of life are attended with a certain amount of expenditure, for the compensation of which a certain quantity of food is requisite, and without a supply of which the duration of life must be inevitably abridged. Both the physical and the mental states here supposed are precisely those, however, in which too large a quantity of food would prove more injurious than too small a quantity. In a word, in a state of health, abstinence is always pernicious, and temperance always beneficial; while, in a state of disease, abstinence is often beneficial, and temperance itself injurious, because what is temperance in health is excess in sickness.

Nothing can remedy the morbid condition induced by long continued abstinence, but food; yet nothing will more certainly or more rapidly extinguish life, than the administration of food, unless it be given with the utmost caution. If a person, after having been long exposed to severe cold, be placed close to a large fire, or be brought at once into a warm room, he will sustain grievous injury, and perhaps die; and, in like manner, if a large quantity of nutritious food be poured into the stomach of a person who has been exhausted by long abstinence, the feeble spark of life that may remain will certainly be extinguished. In Dr. Willan's case, three pints of food,—a pint of milk for breakfast, a pint of mutton-broth boiled with barley for dinner, and as much rice-milk for supper,—were allowed on the third day after an abstinence of sixty days! No wonder that all the symptoms were immediately aggravated, and that the condition of the patient soon became hopeless. One-third of this quantity would have been far too much. To have allowed milk at all was bad, because milk becomes solid in the stomach, and is then more difficult of digestion than other solids, from being unmasticated. In cases like this, a little thickened broth should be given every three or four hours, and the quantity very gradually increased; subsequently, animal food may be allowed; warmth should be promoted by every expedient; frictions are useful auxiliaries, and the bowels should be aided by the occasional use of mild clysters. Internal stimulants are seldom needed; when given at all, the best are ammonia, camphor, the vegetable bitters, and tonics, with small quantities of some anodyne.

ABSTRACTION is an act of the mind, by which it considers a certain attribute of an object, or several objects, by itself, and without regarding any other attributes which the object or objects may happen to possess. Thus, if we see ink, pitch, ebony, and a negro, we see that these objects have in common the attribute of blackness; and this quality we can in thought *draw off* or *abstract* from the various other attributes which they respectively possess; and consider it separately and independently of anything else. In like manner we can consider any attribute of a single object, such as of the sun or moon, without attending to its other attributes; thus we may contemplate the magnitude of the sun without attending to its heat, light, &c.: so we may contemplate the light of the moon, without attending to its magnitude, the inequalities of its surface, &c. All names of classes, inasmuch as the individual members can never be identical, are formed by a process of abstraction. Thus, when we think of a ship or a house, we pay no attention to the materials, colour, shape, size, construction, convenience, or beauty of the ship or house, but we give the one name to any dwelling of man built by regular artificers, and the other to any vessel with a deck and masts made to sail on the sea. Any object which possesses these attributes we call a ship or a house; though there cannot be any ship or house which possesses *only* those attributes, and is not also of a certain colour, size, shape, &c.: but these incidental qualities we leave out of our consideration in referring any object to the class of houses or ships.

From these remarks it is evident that abstraction, being a merely arbitrary act of the mind, by which a certain attribute is considered apart from any other attributes with which it may happen to be associated, does not represent to us images or notions to which there is anything corresponding in the nature of things: there is nowhere an abstract man or tree which has no colour, dimensions, or other incidents not entering into the abstract notion signified by those general terms. Whenever we recognize in any object those peculiarities which we consider as characteristic of a certain class, we refer it to that class, without taking any heed of the *other* attributes with which they may happen to be combined. Thus, if in some unexplored part of the world there should be discovered a race of animals resembling some known variety of the human race in every particular except the colour of the skin or the hair, they would be doubtless called men, although there is no such thing as an abstract man whose skin or hair is devoid of colour.

The circumstance of there not being any sensible object, or any conception of our mind, which we can image to ourselves without its attributes, has given rise to considerable perplexity on the subject of abstraction. For instance, when we think of a horse, we represent to ourselves an animal of certain colour, shape, and size; though we should equally give the name of horse to an animal of different colour, shape, and size. So, when we think of a plane triangle, although a triangle is any plane figure bounded by three straight lines, yet we cannot help representing to ourselves a triangle which is either right-angled, or acute-angled, or obtuse-angled, or equilateral or scalene. The truth is, that the process by which the mind abstracts is, that it conceives or represents to itself the object of thought as an individual of its class, together with certain particular attributes which must belong to all individuals; and it considers apart from the rest only that attribute which is required for the matter in hand. Thus, if it is a question whether a newly-discovered skeleton is that of an animal belonging to the class of elephants or of deer, the comparative anatomist calls to his mind an elephant or deer, such as actually exists, but *considers* only the structure of his bones; and, if there is a close agreement in this respect, he pronounces the skeleton to have belonged to one of those classes. So, likewise, when a mathematician, by means of a figure described on paper, proves that the square of the hypotenuse equals the sum of the squares of the other sides of a right-angled triangle, although the image in his mind is that of a triangle of a definite size, yet he considers only the relation of the sides and angles, without paying any attention to the length of the lines.

This process, by which the mind *generalizes* a particular notion, by considering only a part of it, might be illustrated by many examples of changes in the meaning of words. Thus, there stood formerly on the bank of the Thames in London, a palace called Bridewell; this, in the reign of Elizabeth, was converted into a penitentiary, or prison for hard labour: whence the term *bridewell* has been extended, and is now sometimes used as a general name for such penitentiaries. So the name *palace* has been extended to all sumptuous houses, having originally been confined to that on the *Palatine* hill, at Rome. It has been remarked that, although brute animals have, like men, the faculty of reasoning or drawing conclusions from premises, yet they have not, like men, the faculty of abstraction. Nevertheless, it is plain that some animals go through a process of which the effects exactly correspond with that of abstraction in men: for example, they can count, and are aware of the recurrence of certain numbers; and a dog who has once been beaten with a stick, or pelted with a stone, will run away from all sticks or stones, of whatsoever size, shape, or colour. That they cannot found, on abstraction, the admirable gift of language, the most important distinction between men and beasts, is owing apparently not to the absence of the power of forming general notions, nor yet to the inability of making articulate sounds, as we may perceive in the instance of the parrot.—See NOMINALISTS and REALISTS.

ABSURDUM, REDUCTIO AD, is that species of argument which proves not the thing asserted, but the absurdity of everything which contradicts it. It is much used in Geometry, in order to demonstrate the converse (see CONVERSE) of a proposition already proved. One of two things must be true; either the proposition asserted, or something which contradicts it. If the opposing party denies the proposition, he must affirm that which is contradictory. Let his counter-proposition be taken for granted: then, if, by the legitimate use of it, some absurdity can be deduced, it is evident that his contradiction is wrong, and the original proposition right. As an instance of this method of proceeding, let us suppose it has been proved, and is not denied, that whenever A is B, then C is D. We may then affirm that when C is not D, A is not B. For if A were B, C would be D; but C is not D, therefore A is not B. The strict form of the *reductio ad absurdum*, in this case, is as follows:—You grant that if A were B, C would be D; but you refuse to admit the consequence that, when C is not D, A is not B; that is, you say that C may not be D, and yet A may be B. Let this, then, be as you say, that is, let C not be D, and yet let A be B, But in supposing that A is B, the admitted proposition obliges you to say that C is D. But you have supposed that C is not D, you therefore say at the same time that C is D, and that C is not D, which is absurd. Consequently, if it be true that, whenever A is B, then C is D, it follows that, when C is not D, A is not B.

The *reductio ad absurdum* has been objected to as not equally conclusive with direct demonstration. For this there is no foundation; though it must be admitted that direct demonstrations are more pleasing and more elegant. But it is obvious that, if everything which contradicts a proposition be false, the proposition itself must be true. The student of logic must distinguish between that which is only *contradictory*, and that which is *contrary* to a proposition. Thus, to the proposition that 'all squares are equal,' it is contradictory that '*some* squares are not equal,' and contrary, that '*no* squares are equal.' The contrary is the most complete contradictory, and affirms that the proposition is true in no one instance. It is not correct to say that, if a proposition be false, its contrary is true; for example, it is false that all squares are equal, and equally false that no squares are equal. But of a proposition and its contradictory one must be true; thus, either all squares are equal or some squares are not equal. Hence, whatever disproves a proposition proves something contradictory, and whatever disproves everything contradictory proves the proposition. The *reductio ad absurdum* is, therefore, as conclusive as direct demonstration.

ABU BEKR, properly called ABDALLAH ATIK BEN ABI KOHAFAH, but better known under the name of ABU BEKR (*i.e.* 'Father of the Maiden,' in allusion to his daughter Ayeshah, whom the Arabian prophet married very young), was the first caliph or successor of Mohammed in the government of the new empire founded by him. Mohammed died in A.D. 632, without leaving male issue. The succession to the sovereignty was at first contested between his father-in-law, Abu Bekr, and Ali ben Abi Taleb, his cousin-german, who was also, through marriage with the prophet's daughter Fatima, his son-in-law. Between the two rivals themselves the dispute was settled without an appeal to arms. Abu Bekr prevailed, and Ali, though disappointed, submitted to the authority of his successful opponent. But among the Mohammedans the respective claims of the two competitors became a point of perpetual controversy, and gave rise to the great division of the whole Mohammedan community into Sunnites and Shiites; the former asserting the right of Abu Bekr and his two successors, Omar and Othman, while the Shiites condemn these three caliphs as unlawful intruders, and maintain the exclusive right of Ali ben Abi Taleb and his lineal descendants to the commandership over the Faithful.—[See article ALI BEN ABI TALEB.]

After the death of Mohammed, several of the Arabian tribes, who had become converts to the religion promulgated by him, shook off their allegiance to his successor. Only the three important towns of Mecca, Medinah, and Tayef declared themselves for Abu Bekr. It was the first and principal object of the newly-appointed sovereign to establish his authority in the other parts of Arabia, especially in the countries of Yemen, Tehama, Oman, and Bahrain. In reducing to obedience these refractory provinces, Abu Bekr was powerfully supported by Omar, afterwards his successor, and especially by Khaled ben Walid, a military commander of extraordinary courage and presence of mind. Besides this rebellion of some of its members, the Mohammedan state had to encounter other difficulties from several new pretenders to prophetship, who came forward in different parts of Arabia, and some of whom soon gathered numerous adherents around them. Among these the names of Osud al Abbasi, Tolaihah ben Khowaised, and Mosailamah deserve to be mentioned. Whatever disturbance these new pretenders might cause among the faithful Moslems, the firmness of their belief in the mission of Mohammed could not be shaken, since he himself had prepared them for the appearance of such impostors. Mosailamah seems to have been the most formidable of these enemies of the Islam. He was however defeated by Khaled, and killed in a battle near Akrabah. This conflict is memorable also on another account. The precepts promulgated at different times by Mohammed had, till then, never been collected in a volume; they were handed about in fragments written on palm-leaves or pieces of parchment, and in a great measure preserved by oral tradition. Many of the personal associates of Mohammed, who were from memory familiar with his doctrine, fell in the war with Mosailamah; and Abu Bekr, in order to obviate any future uncertainty about the genuine text of the ordinances, caused all the fragments to be collected, the passages remembered by heart to be written out, and the whole to be embodied in the volume known under the title of the Koran—a work which, from the importance of its contents, as well as the force and purity of its language, is the sacred and classical book of the Mohammedans.

When the authority of the caliphat was fully established in Arabia, Abu Bekr was anxious to increase the Mohammedan dominions by foreign conquest. Khaled was dispatched into Irak, and subdued several of the frontier provinces along the Euphrates, which belonged to the then declining empire of Persia; while two other commanders, Yezid ben Abi Sofyan and Abu Obeidah, with an army gathered from all parts of Arabia, entered Syria and defeated the troops of the Grecian emperor Heraclius. They also got possession of the town of Bostra, favoured, it is said, by the treason of its governor Romanus. But the siege and capture of Damascus by the united forces of Abu Obeidah and Khaled, which event was preceded by a decisive victory over a Greek army of 70,000 men near Ajnadain, forms the principal feature of this expedition, as it established the dominion of the Arabs over Syria, and in fact over the whole country between the Euphrates and the Mediterranean.

On the day of the capture of Damascus (23rd August, A.D. 634) Abu Bekr died, at the age of sixty-three years. Not one of his three sons, Abdallah, Abd-al-rahman, and Mohammed, survived him; and in his will he appointed Omar as his successor. Eastern writers praise the almost austere simplicity of his habits and manners, and his entire disregard of wealth, and the luxuries or even comforts of life. So determined was he not to be enriched by his elevation to the supreme command, that every Friday he distributed all the surplus of his income among such persons as he thought deserving of it. His short reign, of little more than two years, forms an eventful epoch in the history of Mohammedism; and Oriental authors have vied with one another in recording details about the early conquests of the armies of the Faithful. The volume of the great Arabic chronicle of Tabari, lately edited and translated by Kosegarten (Greifswald, 1831. 4to.), is entirely occupied with only the earlier part of Abu Bekr's reign; the latter part, or the history of the conquests of Irak and Syria, still remains unpublished. A highly interesting account of the siege and capture of Damascus, derived chiefly from the Arabic chronicle of Wakedi, may be found in Ockley's *History of the Saracens*.

ABULFARA'GIUS, properly MAR GREGORIUS ABULFARAJ, also called GREGORIUS BARHEBRÆUS, was an Oriental writer of much celebrity, who lived in the thirteenth century of our era. He was born in A.D. 1226, at Malatia or Melite, a town situated near the western bank of the Euphrates in Lesser Asia, where his father, Aaron, followed the profession of a physician. Though the offspring of a Jewish family, he embraced the Christian belief, to which he continued faithful till his death. It is, indeed, surmised that shortly before his death he renounced Christianity; but this unauthenticated report is sufficiently counterbalanced by the unqualified praise with which his name is mentioned by Christian writers, who would not have allowed such a fact to remain unnoticed. Abulfaraj studied theology, philosophy, and medicine. He spent the greater part of his life in Syria. At the early age of twenty years he was appointed Bishop of Guba, and subsequently of Aleppo. In 1266 he was elected Primate of all the Jacobite Christians in the East. He died at Meragha in Azerbijan, A.D. 1286.

Abulfaraj was the author of a great number of Arabic and Syriac works, but the composition through which his name has become best known among us is a universal history, originally written in Syriac, but subsequently translated by the author himself into Arabic, to which he has given the title of *History of the Dynasties*. It is divided into ten sections; the first of which gives some account of the patriarchs; the second of the Jewish commonwealth under the judges; and the third of the Jews under the kings; the fourth contains the history of the Chaldæans; the fifth of the Persians; the sixth of the Greeks; the seventh of the Romans; the eighth of the Christian Grecian empire; the ninth of the Mohammedan Arabs; and the tenth of the Mogols. In the early part of the work many errors are observable into which the author has fallen through his ignorance of the classical languages and literature. The section treating of the Mohammedan history is written with greater accuracy; and in his account of the Mogol dynasty, towards the conclusion of the work, Abulfaraj speaks from his own knowledge and experience as an eye-witness. Though written by a Christian, this work is held in high esteem even among Jews and Mohammedans in the East. To us its chief interest consists in the curious details which it contains concerning the history of science among the Arabs, particularly under the three Abbaside caliphs, Mansur, Harun al Rashid, and Mamun. An edition of the Arabic text of the *Dynasties*, accompanied with a Latin translation, was published by Edward Pococke, at Oxford, in 1663, 4to.; the Syriac text, likewise with a Latin version, was edited by Bruns and Kirsch, at Leipzig, in 1789, 4to.

ABUL FAZL, son of Sheikh Mobarik, was the vizir of the celebrated Mogol emperor Akbar, who reigned from A.D. 1555 to 1605. Of the history of his life few details are known to us. In 1602, when returning from an expedition to the Deckan, he was murdered in the district of Nurwar by banditti, and, it was suspected, by the contrivance of Akbar's son Selim, who afterwards succeeded his father on the throne, under the name of Jehangir. The extensive and valuable works, which, notwithstanding the duties of his high office, Abul Fazl found leisure to write, have ensured him a conspicuous place among the best authors, as well as among the most enlightened statesmen, of the East. His principal work is the *Akbar-Nameh*, which exists as yet only in MS., and contains a history of the reign of the sovereign whom he served, and to whom he was most devotedly attached; this history Abul Fazl carried down till very near the time of his own death, and it was afterwards continued by Sheikh Enaiet-ullah in a supplement, entitled *Takmileh-i-Akbar-Nameh*. But the work which has most contributed to make his name familiar to us, is the *Ayin-i-Akbari*, or *Institutes of Akbar*, a statistical and political description of the Mogol empire, and of the several branches of its administration, some account of which will be given hereafter. [See Ayin-i-Akbari.] Abul Fazl was a friend to the oppressed Hindus. It appears that the exertions which he made for their protection, and the zeal with which, assisted by his brother Feizi, he endeavoured to derive a precise notion of the nature of their political and religious institutions from their own ancient codes, prejudiced many narrow-minded Mohammedans against him. In his Persian prose translation of the great Sanskrit heroic poem, the *Mahabharata*, Abul Fazl has left us a curious and valuable monument of the persevering diligence which a Mohammedan statesman deemed it worth his while to bestow on the literature of the conquered nation, in the government of which he was called to assist by his counsels. Another of his works, less interesting to us, though much admired in the East on account of its refined and florid style, is the *Ayar-i-Danish*, or *Touchstone of Intellect*, a Persian translation from the Arabic of the well-known fables of Bidpaï, or Pilpay.

ABU'LFEDA, or, with his full name, Emad-eddin Abulfeda Ismaïl ben Ali, was the descendant of a collateral branch of the Ayubite dynasty, which Saladin, in A.D 1182, appointed to the sovereignty of the three towns Hamah, Maarrah, and Barin, in Syria, and which continued to hold that dignity even after the Bahrite Mamluks, under Azz-eddin Ibek, had, in A.D 1254, put an end to the Ayubite dominion over Syria and Egypt. Abulfeda was born in A.D. 1273, at Damascus, whither his family had fled before the Mogols, who then threatened Syria with an invasion, but were successfully repelled by the Bahrite Sultan Bibars. Mohammed ben Basel, once sent as ambassador to the German Emperor, Frederic II., is mentioned as having been one of his teachers. He began at an early age to display a warlike disposition, and to join in the expeditions against the remains of the Christian kingdom founded in Syria by the Crusaders. In 1285 he was present at the siege of Markab,—in 1289 at that of Tripoli,—and in 1291 at the taking of Akka (St. Jean d'Acre); at a later period (A. D. 1298), he accompanied his cousin Modhaffar, then the reigning prince of Hamah, on an expedition against the Mogols. After the death of Modhaffar, in 1299, the Bahrite Sultan Nasir declared the fief which the Ayubites held under him to have become extinct, and assigned a small pension for their maintenance. When, however, ten years afterwards, Sultan Nasir became personally acquainted with Abulfeda, he not only restored to him (1310) the former dignity of his family, but soon after, as an acknowledgment for his services, raised him to the rank of *malik*, or king. In 1316, Abulfeda was obliged to give up the town of Maarrah and its territory to the Arab Emir Mohammed ben Isa, who demanded this boon as a reward for his defection from the Mogols; but he retained Barin and Hamah, and, with his troops, often rendered military services to Sultan Nasir. Already in 1315 he had assisted him in an expedition against the town of Malatia or Melite, which had shown itself favourable to the cause of the European Christians, and to the Mogols. He continued on the most friendly terms with Nasir, till he died in 1331. The numerous works which he has left behind attest the extent and variety of his information. Among them we find mentioned works on medicine, Mohammedan jurisprudence, mathematics, and philosophy; those most commonly known are a treatise on geography, entitled *Takwim al-boldan*, or 'Disposition of the Countries,' and an historical work called *Mukhtasar fi akhbar al-bashar*, i. e., 'A Compendium of the History of Mankind. The geographical treatise consists of an introduction and twenty-eight sections on particular countries, each containing, first, a table, showing the latitudes and longitudes of the most remarkable places, and afterwards detailed statistical and topographical notices respecting them. Besides his native country, Abulfeda had seen Arabia, whither he went twice on a pilgrimage to Mecca, and also Egypt, which he visited frequently when he took the customary annual presents of homage to the court of the Sultan. In the description of such places as he had not seen himself, he takes care to name the authorities from whom he draws his information. A uniform edition and translation of the entire geographical work of Abulfeda is still a desideratum in oriental literature; the descriptions of single countries have been edited by Gravius, Reiske, Rommel, Kœhler, Michaelis, and others. The historical work is a chronicle after the usual comprehensive plan of Oriental works of this kind. It commences with a brief and very imperfect sketch of the ancient history of the Jews, Persians, Egyptians, Greeks, Romans, &c.; then gives some information about the history of the Arabs before the time of Mohammed, and thus passes over to its main object, the history of the Prophet, and of the Arabian empire, which it carries down as far as the year 1328. The earlier centuries of the Mohammedan power are but briefly treated, and many important events—for example, the conquest of Spain by the Arabs—are entirely passed over. Farther on the narrative becomes fuller and richer in interesting details. For the history of the Crusades it is one of the most important Oriental sources which we possess. The latter part of the work, or the history of Mohammedanism, was translated by Reiske, and edited with the Arabic text by Adler, at Copenhagen, in five vols. 4to. 1789-94; an edition and translation of the ante-Islamitic part has been published by Fleischer, Leipzig, 1831, 4to.

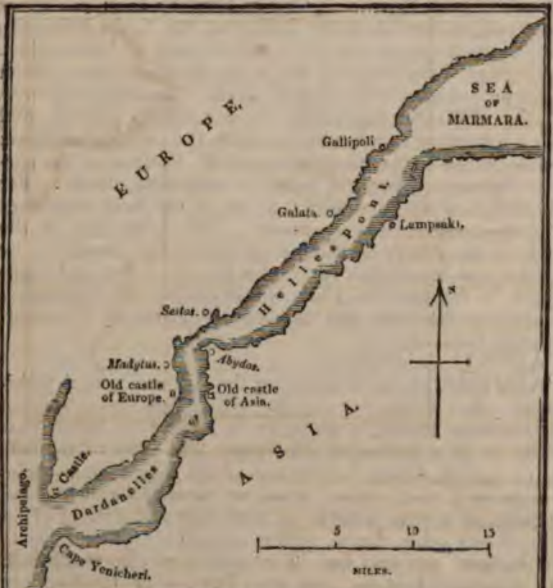
ABURY, see Avebury.

ABUTMENT, in building, or the practice of civil architecture, that which receives the end of, and gives support to, anything having a tendency to spread or thrust outwards, or in a horizontal direction. The piers or mounds on, or against, which an arch that is less than a semi-circle, or a series of such arches, rests, are abutments; while the supports of a semi circular or semi-elliptical arch, or of an arch of any other figure, which springs at right angles to the horizon, are imposts. The arches of the Southwark and Vauxhall bridges, over the Thames at London, are small segments of circles, even less than quadrants, and all their piers are abutments or abutment-piers; the arches of the London, Blackfriars, Waterloo, and Westminster bridges are all semi-ellipses, and their piers are imposts, or impost piers, and not abutments. Nevertheless, the piers at the extremities of a bridge, of whatever form its arch or arches may be, are always termed its abutments; that is, abutments of the bridge itself; for the road-way of most bridges forms the arc of a circle, and may be considered an outer arch, whose abutments are the land-piers. Level bridges, such as Waterloo-bridge, cannot, indeed, be said to have abutments, in the technical and more restricted sense of the term; but in its more general acceptation, as mounds or props which receive the ends of the series of arches of which the bridge is composed, and tend to prevent the possibility of their spreading, the land-piers of a level bridge also are abutments.—[See Buttress and Impost.]

ABUTTALS (from the French Abutter, to limit or bound) are the buttings and boundings of lands to the east, west, north, and south, showing by what other lands, highways, hedges, rivers, &c., such lands are in those several directions bounded.

The boundaries and abuttals of corporation and church lands, and of parishes, are usually preserved by an annual procession.

ABY'DOS, an ancient Greek town on the Asiatic shore of the Hellespont, now the Dardanelles, and nearly opposite Sestos on the European shore. It is said by Strabo to have been founded by the Milesians; but the date of its foundation, like that of many other Greek towns, is not accurately known. Abydos was burnt by Darius the Persian, after his Scythian expedition; and somewhat later (B.C. 480) the people of Abydos witnessed the immense army of Xerxes cross the stream on a bridge of boats.—(See *Outline of General History*, chap. viii.)—This bridge did not extend from Abydos to Sestos, which was a distance of more than three English miles, but it was formed at a narrower part, where the distance is somewhat less than one mile. It commenced on the Asiatic side, a little higher up the stream than Abydos; its termination, on the opposite coast, was at the projecting point opposite to Abydos, and between Madytus and Sestos. The practice of crossing large streams by means of boats lashed together, and covered with planks, was common among the Persians; nor were they used only for temporary occasions, but existed in the time of Herodotus and Xenophon over the great rivers of Western Asia, as they do now over the Tigris at Bagdad, the Euphrates, at Hillah near the ruins of Babylon, and elsewhere. When Darius, the father of Xerxes, crossed the channel of Constantinople, on his Scythian expedition, the bridge of boats was constructed by a Greek of Samos, who endeavoured to perpetuate his glory by causing a painting of the passage of the army to be put up in the great temple of Juno at Samos. A description of the bridge of Xerxes is given by Herodotus (vii. 36), who was on the spot probably much less than half a century after the event.



[The ancient names are in italics.]

The passage of Abydos has obtained a poetical celebrity from the story of Leander, who used to swim across the stormy waters of the Hellespont to visit his mistress Hero, whose name was commemorated even as late as the beginning of the Christian æra by a building called the Tower of Hero. There is extant a Greek poem by Musæus, who perhaps lived about the fourth century, descriptive of the love and tragical fate of Leander. In our own days Lord Byron has given a new interest to these localities by his poem of the *Bride of Abydos*.

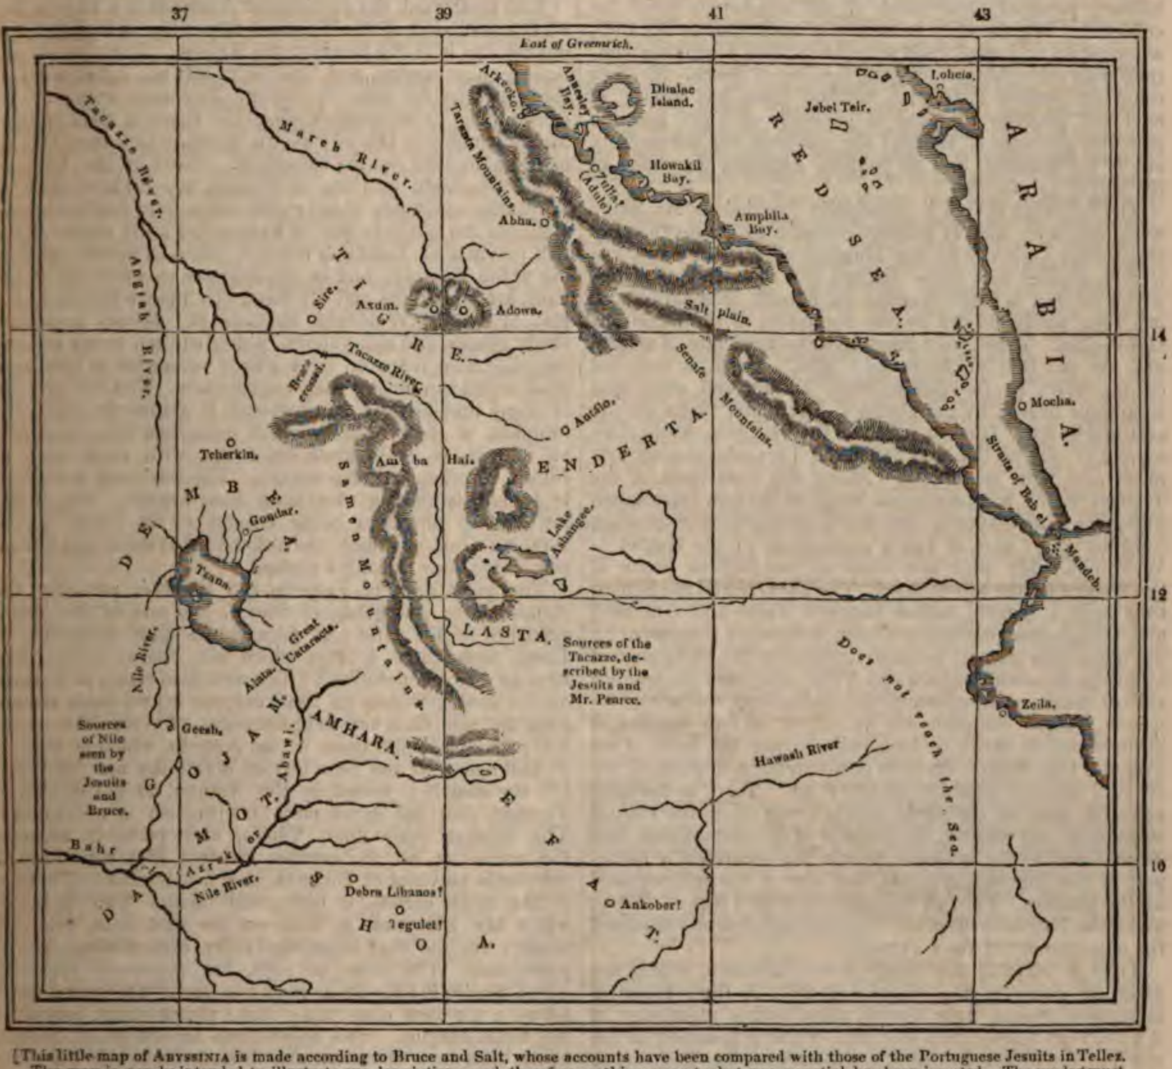
ABY'DOS, an ancient city of Upper Egypt, the remains of which are found near two villages, El Kherbeh and Harabat, about six miles from the west bank of the Nile (N. lat. 26° 12'). The chief building, which still remains, is nearly covered with sand, but the interior is in good preservation. Contrary to what we observe generally in Egyptian buildings, this edifice is constructed of both limestone and sandstone. In the interior it is said that constructed arches are found, similar to those of brick which Belzoni describes at Thebes. The numerous apartments in this building, and the style of decoration, show that Abydos was once a place of importance, and possibly a royal residence. When Strabo was in Egypt (about the commencement of the Christian æra) Abydos was a mere village, but he learned that the great building was called a Memnoneion, or palace of Memnon, and that tradition assigned to Abydos a rank in ancient time next to Thebes. 'There is,' says the geographer, 'a canal leading to the place from the river' but, besides this communication with the main stream, Abydos had the advantage of standing on the great canal which runs northwards, and is best known by the name of the Bahr Youssuf, though the *name* commences much farther north, at a place called Tarut es Sheriff.

In the year 1818, Mr. W. Bankes discovered on an interior wall of a building at Abydos, not belonging to the great edifice, a kind of tablet or genealogy of the early kings of Egypt, which is now generally called the Table of Abydos. Mr. Bankes made a copy of this, and others have been since made by Caillaud, Mr. Wilkinson, Burton, and others. The copy which we have before us is one by Mr. Burton, which is more complete and correct than that in Salt's Essay, which was made by Mr. W. Bankes. This tablet consists of three compartments lying horizontally one above another, and each compartment has been divided into twenty-six rectangles, so that the whole has once contained seventy-eight rectangles. No one compartment is perfectly entire, but enough remains of the lowest to enable us to determine the original dimensions of the whole table, and the number of compartments. Each of these rectangles contains an elliptical ring, or cartouche as it is sometimes called, such as may be seen on the Egyptain monuments in the British Museum; and each cartouche contains those various figures which are now generally admitted to indicate the names or titles of sovereigns. The lowest of the three compartments contains in the nineteen rectangles, which are complete, the title and name of Ramses the Great, perhaps the Greek Sesostris; the same prænomen or title, and name, having each probably been repeated thirteen times in the whole twenty-six rectangles, of which seven, as we have just stated, are erased. Deducting these twenty-six, we have remaining in the other two compartments fifty-two rectangles: the fifty-first and fifty-second contain the title and name of a Ramses, who may be a predecessor of Ramses the Great. The cartouches preceding these are probably the titles of kings; for example, the forty-seventh is the same as that on the great colossal statue at Thebes, and on the entire colossal statue in the British Museum, which is Amenophis II. (in Manethon's Catalogue), or the Greek Memnon. Whether the forty-six cartouches that precede this of Memnon belong to kings, his lineal predecessors, we cannot undertake to assert or deny.—[See article in the *Westminster Review*, No. xxviii. p. 405; vol. ii.]

ABYSSINIA. It is difficult to give, in a limited space, any very complete account of the country called Abyssinia, and this difficulty arises no less from the extent of the subject than from the want of sufficiently comprehensive and trustworthy documents. We shall endeavour, in this article, to give a brief description of the country, and to state the chief authorities for our present knowledge of Abyssinia, pointing out generally how far they are satisfactory.

The name of Abyssinia became known in Europe from the Portuguese missionaries who penetrated there. Tellez tells us that the name of the people is *Abexins*; but the Portuguese often write the names of the country and the people respectively in the Latinized forms of *Abassia* and *Abassinos*, from which our common term *Abyssinia* is derived. But as it frequently happens that we call a country by a name not used by the inhabitants themselves, so in this case we are informed by Ludolf that the word *Habesh* is Arabic, and signifies a mixed people, though the proof of the Abyssinians being a mixed people, as well as of their having originally emigrated from Arabia, has never yet been given. The name of Ityopayawan, or Ethiopians, is that which is adopted by the people when speaking of themselves, though we cannot say how far it is still in general use. They more commonly name themselves with reference to the great divisions to which they belong, such as people of Tigré, Amhara, &c.

The political boundaries of the country to which we give the name of Abyssinia have varied since the Portuguese first made us acquainted with it, as we may see from Tellez' *History of Ethiopia;* but to trace all these revolutions would not be a very easy or a profitable labour. The present political limits of Abyssinia will be given below. Though the term Abyssinia strictly belongs to a particular political division of Africa, it is often used in a vague sense as referring to an extensive country remarkable for the physical conformation of its surface. We shall endeavour to define what part of Africa may be conveniently comprehended under this term. Abyssinia is an alpine country, of high table-land, north of the equator, and containing the sources of two of the largest branches of the Nile, the Tacazzé, and the Bahr el Azrek or Abawi, besides the Mareb. Its nearest approach to the sea is in the Baharnegash territory, which forms the N.E. mountain-terrace of Abyssinia, and overlooks the flat coast near Arkeeko (N. lat. 15° 35′, E. lon. 39° 37′), on the Red Sea. The rulers of Abyssinia have at present no command of the sea-coast, Masowa and Arkeeko, &c. being in the hands of the Mohammedans. A series of terraces conducts from the west coast of the Red Sea to a high mountain range, which runs nearly parallel to the sea-coast for probably 300 miles, and forms a boundary between two different climates. Beyond this limit southwards we are not able to state its direction. Towards the north and north-west the mountain region of Abyssinia sinks down into the level countries of Sennaar and Kordofan: its greatest width from north to south it is at present impossible to state. By combining the maps of the Jesuits with Bruce's observations, it may be true that, following the meridian which runs through the great lake Dembea, this range may extend nearly 250 miles from the north limit bordering on the kollas, or low grounds of Tcherkin and Waldubba, to the almost unknown southern slope. On the south-east the terrace declines along the provinces of Shoa and Efat, which is indicated by the streams which water part of these provinces taking an east or a south-east course. We do not yet know whether or not the high land which divides the waters that feed the Bahr al Azrek from those that flow towards the Red Sea or the India Ocean, is continued westward or south-west towards the interior of Africa, though such a continuous range or high terrace seems exceedingly probable. The Bahr el Abiad itself, the main stream of the Nile, most probably has its rise in some lakes in a high table-land. This high table of land of Abyssinia is probably continued southward also. All we at present know about it is from the journey of Antonio Fernandez, which is briefly given in Tellez, but in such a way as to convey very little information. This zealous missionary left Dembea in March 1613, and crossed the Nile at the point where it turns to the north: he then went due south, and in the course of his journey crossed a large stream called the Maleg, and arrived at the kingdom of Narea, the north part of which lies in about 8° of north latitude. This country appears to be a kind of continuation of the high ground of Abyssinia, but as to its absolute elevation we know nothing at all.



[This little map of Abyssinia is made according to Bruce and Salt, whose accounts have been compared with those of the Portuguese Jesuits in Tellez. The map is merely intended to illustrate our description; and, therefore, nothing except what was essential has been inserted. The reader must infer the directions of many hills and mountains from the courses of the rivers, which, however, are very imperfectly known. Such places, as have not had their position determined with some degree of certainty, have a note of interrogation placed after them.]

The accounts of the Portuguese may still be considered as authority for many facts relating to Abyssinia, and the reader may see in the learned work of Job Ludolf how much information that industrious scholar was able to extract from them. Ludolf had also the advantage of personal acquaintance with Gregory, an Abyssinian then in Germany. Lewis Poncet, a French physician, who visited Gondar in 1699, to cure the king of some complaint, published an account of his journey. Finally, Mr. Bruce, in 1770, entered the country, and published an elaborate account of it sixteen years after his return. For reasons which we shall state more fully under the article BRUCE, we cannot here make so much use of that traveller as of Mr. Salt; and our notice of all those parts of Abyssinia which we know either entirely or principally from the travels of Bruce, must necessarily be very brief and imperfect. Though Bruce is often confirmed by the more recent traveller, we do not feel entire confidence in his accounts of those parts, which are known only from his own personal observation or the information which he collected. We therefore trust nearly altogether to Mr. Salt, whose plain and unadorned statements form a striking contrast with the rhodomontade and egotism of Bruce. Mr. Salt could not proceed to Gondar, because there was a kind of civil war between the Ras or governor of Tigré and the powerful governor of Gojam; the emperor was left entirely out of the question, and his political condition depended on the will of his viceroys.

The following sketch is principally founded on Mr. Salt's work, which we may at present consider as almost the only trustworthy authority for the kingdom of Tigré. Abyssinia is now divided into three distinct and independent states, which division is partly founded on natural boundaries, and has been partly caused by the incursions of the barbarous Galla tribes. These three great divisions are Tigré, Amhara, and the province of Shoa with Efat. Tigré is bounded on the north by the Bekla, Boja, Takué, and some wild Shangalla tribes; by the Danákil, Doba, and Galla on the east and south. It is separated on the west from Amhara by a great branch of the Nile called the Tacazzé, running first north and then north-west. Along the west bank of the Tacazzé is the bold mountain range of Samen (mentioned under the same name in the Adule inscription), extending from the south part of Lasta northwards to the district of Waldubha. Mr. Salt saw snow on the highest peaks of the Samen on the 8th of April. The Tacazzé and the Samen thus form a natural barrier between Tigré and Amhara; and though one province has been frequently conquered by the other, this natural boundary, joined to the difference of language between Amhara and Tigré, and other causes, has always made a real, effective, and permanent union impracticable. Tigré comprehends an extent of four degrees of latitude and as many in longitude, having the form of an irregular trapezium. Its most northern point is about 15° 35′ N. lat.; the most southern about 11° 20′. Tigré is the most powerful state of the three, which arises from the natural strength of the country, the courage of the inhabitants, and its proximity to the sea-coast, which has secured it a monopoly of the imported muskets, and also of the salt required for the interior. Though nominally held by a Ras or viceroy, under the Negus or emperor, it has not unfrequently assumed the appointment of the sovereign.

Tigré is properly the name of one province, which has given its name to the whole country. A high range of mountains passing near Adowa, about twelve miles east of Axum, runs through this province, which is bounded on the north by the Mareb (which is a tributary to the Tacazzé, or is lost in the desert), on the east by Agamé, on the west by Sire, and on the south by the Warré, which runs westward and joins the Tacazzé. This province contains ten chief subdivisions, and many others of little importance: 'its general character is that of a range of hill-forts, or "ambas," intersected by deep gullies and highly-cultivated plains.' The chief places are Adowa and Axum (see AXUM and ADOWA). East of Tigré is Agamé, which is rich and fertile, and on a level at a considerable elevation above the sea. A lofty mountain range forms its eastern frontier, which range, on the south-east, separates it from the great salt plain. The chief town is Genata. South of Agamé, Enderta comprises a great number of petty subdivisions, some of which form the eastern mountain boundaries of the great province of Tigré. The capital of Enderta is Antálo, N. lat. 13° 22′, E. long. nearly 40°, a position well adapted to protect the southern frontier against the Galla; on this account the Ras, or viceroy, has chosen it for his residence. Chelicut, near Antâlo, is the country residence of the Ras. South of Enderta, Wojjerat runs east and west: it contains extensive forests, which abound in elephants, lions, rhinoceroses, and all kinds of game. It is also famed for its white honey. The inhabitants, who are a fine race of men, are said to be descendants of Portuguese soldiers settled in the country. The small and low district of Wofila, bordering on Wojjerat, contains a fresh-water lake called Ashangee, the greatest length of which, according to Salt's map, is about twenty-six miles. The rugged province of Lasta (called Bugna by the early Portuguese writers), filled with almost inaccessible mountains, is the most southern part of Tigré. The language of Lasta is Amharic. North of it are two other small mountainous districts, Salowa and Bora; the low lands between which and the east bank of the Tacazzé are in the hands of Christian Agows.

Still northward, the province of Avergale is a narrow belt on the east bank of the Tacazzé, fifty miles in length; this district also is in the hands of the Agows. Their houses are built without mortar, and 'the better sort are constructed in the characteristic form of ancient Egyptian temples.' In confirmation of his remark about the forms of their houses, Mr. Salt refers to one of his own plates, which does not, in our opinion, bear out the statement. West of the Tacazzé is the mountain province of Samen, the highest land in Abyssinia, extending about eighty miles from north to south. Between the northern part of Samen and Tigré proper is the rich province of Temben; north of Temben is Sire, stretching to the Tacazzé; and on the opposite, or west side of the river, are Waldubha and Walkayt, which pay a tribute to the Ras of Tigré. Waldubha abounds in 'flowery meadows, shady groves, and rich valleys,' which contain many solitary devotees, who, however, have hardly succeeded in getting a good reputation among their countrymen. The last division of Tigré that we have to enumerate is commonly called the kingdom of Baharnegash, which comprises many districts, all now ruled by separate chieftains, with such titles as Shum, Kantiba, or Baharnegash. The last word, according to Ludolf, is nothing more than *Bahr-negash*, 'lord of the sea;' these provinces being nearest to the coast of the Arabian Gulf, on which the rulers of Abyssinia had once a power that they no longer possess.

The great river of Tigré is the Tacazzé, probably the Astasabas or Astagabas of Strabo, and one of the larger branches of the Nile. It rises in the high mountains of Lasta, from three sources which Mr. Pearce visited, and runs as we have described. The mountain range of Samen, on the west, prevents its receiving any considerable stream from that side, till it arrives in the region of Waldubha, where it is joined on its left bank by the Angrab, which is marked in Salt's map as the boundary of Waldubha and Walkayt. On the east it is joined by the Arequa, in the district of Temben, but the exact point of junction is not known. The Arequa rises near Antálo, and probably receives the waters of all the smaller streams that run through the fertile province of Enderta, as it has a wide bed which, in the rainy season, is often well filled. The Tacazzé, when Mr. Salt saw it, was, on the east side, low and sandy; but the west bank was rocky, and in some places precipitous. The river, he says, has numerous overfalls, which render it fordable at most seasons of the year; while between the fords deep holes occur, the favourite retreat of the hippopotamus. This amphibious animal, called *gomari* in the language of the country, is common in the Tacazzé; and Mr. Salt, with his companions, found, by experiment, that leaden balls from a musket seemed to make no impression on the hard heads of the monster. Crocodiles, called by the natives *agoos*, are of an enormous size in the Tacazzé, and more dreaded than the hippopotamus: those which Salt saw seemed to be of a greenish colour. The other great river of Tigré is the Mareb, which, rising in the mountains of Taranta, that form the north-eastern boundary of Tigré, flows north-west, and probably joins the Tacazzé in the kingdom of Sennaar: report says it is lost in the desert. Between Antâlo and the sources of the Tacazzé, Mr. Pearce only met with one small stream.

We shall now proceed to give a description of the mountain system of Abyssinia, which will be more intelligible after the kind of outline we have attempted. Abyssinia may be correctly called an Alpine land, and as it has never yet been well explored, our description of it must necessarily be very incomplete, and must depend altogether on the routes of the few travellers who have visited the country. The authorities are the accounts of the early Portuguese missionaries, Ludolf's *History of Ethiopia*, Poncet, Bruce, and the most important of all, Salt's and Valentia's travels. That part of the Alpine land of Abyssinia which lies between the Tacazzé and the Red Sea, and forms the kingdom of Tigré, being the best known, will have the most particular description.

Tigré has no sea-coast. The west side of the Arabian gulf, from about fifty miles above the straits of Bab-el-mandeb, as far as the bay of Massowa, is occupied by the Dancali, the Damhoeta, and Hazorta tribes. Arkeeko, on the bay of Massowa, is the only point of the Red Sea through which the people of Tigré can with any ease communicate with Asia; and it was one object of Salt's mission to ascertain what kind of commerce might be opened with Abyssinia in this direction. The Abyssinians, in the early centuries after the Christian era, carried on their commerce nearly as they do now; the only difference then was, that Zulla, the ancient Adule, about forty miles south-east of Arkeeko, was their sea-port in those days.

As the traveller advances from the dry sands of Arkeeko southwards, small elevations begin to appear on the second day, and on the fifth day he reaches the granite ridge of Tubbo, where the whole country assumes a different appearance, and instead of the mimosas that mark the region of sand and heat, the traveller's eye is greeted with hills, brooks, and forests, full of antelopes, monkeys, and elephants. Here the caper and tamarind trees, with their fruit, are seen; and tne fig sycamore. Two days more bring the traveller to the pass of the Taranta mountain range, where he must leave his camels, and make use of mules and oxen. The rocks at the foot of Taranta are described by Mr. Salt as a reddish species of granite; the ascent is at first gradual, though incumbered with fragments of rock, but afterwards it becomes so steep that riding is almost dangerous. The Abyssinian baggage-carriers cheer themselves by singing as they lightly mount the rugged paths. The vegetation changes with the ascent; and in one part where Salt observed, what he calls chalkstone, a hardy kind of cedar, called tud, was found in abundance. The descent from the summit of Taranta towards Dixan, which is the south-west side, occupies only a short time, and the traveller is now on one of the high terraces of Tigré. 'The view,' says Salt, 'that bursts upon the traveller, as he begins to descend the southern side of Taranta, is one of the most magnificent that human imagination can conceive, extending over the abrupt mountains of Tigré to the pinnacled and distant heights of Adowa.' On each side of this mountain range the seasons differ. On the south side, March 3rd, Salt found the heat intense, compared with what he had felt north of the Taranta, and the country dried up, while the cattle had all been driven across the mountains, in search of pasture. This region may be considered as the first terrace of Tigré, or that part of the kingdom called Baharnegash; it extends south from the Taranta pass about four days' journey, and north-westwards over the green meadows of Serawe, as far as the Mareb. The people here are dark-coloured, and speak the Geez language. Indian corn grows well in the country; large black sheep and white fine-haired cattle are abundant. Two roads lead from Baharnegash to Gondar, the capital; one which turns south and passes through Antálo; the other runs south-westward through Adowa, Axum, and Sire.

Mr. Bruce observed a phenomenon in passing the Taranta, which is not unusual in mountainous countries, only the violence of it in Tigré is perhaps something extraordinary. On the 17th November, the mountain tops were hid in clouds, and loud thunder was heard. 'The river scarcely ran at our passing it; when, all on a sudden, we heard a noise on the mountains above, louder than the loudest thunder. Our guides on this flew to their baggage, and removed it to the top of the green hill, which was no sooner done than we saw the river coming down in a stream about the height of a man, and the breadth of the whole bed it used to occupy.' An antelope was surprised by the torrent, and driven to Mr. Bruce's station. Mr. Pearce (Salt, p. 318) experienced a similar storm on the 27th of August, in his journey from Amphila Bay to Chelicut, before he reached the main ridge of the mountains. The 'gorf' or torrent came down so suddenly, that it swept away two camels which were in the bed of the river, and the people saved themselves with difficulty by climbing the rocks that bordered the stream. One camel was afterwards found alive jammed in between two rocks, and the other about a mile and a half lower down entangled in the boughs of a tree.

The plains on the top of Taranta are, in many places, sown with wheat, which Bruce found ready to cut in November. Mr. Salt, on his return from Adowa to Arkeeko by a new route, over that part of the Taranta which he calls Assauli, gives a beautiful picture of the highest parts of the mountain. 'The contrast which the scene before us now presented was very extraordinary; immediately in front lay a verdant plain, on which the natives were busily engaged, some in tending their cattle, and others in gathering in a field of wheat (May 22nd), while beyond an extensive prospect opened to the view over the burning regions of the Tehama, on which might be distinguished, at a distance, the mountain of Ras Giddam, the Island of Massowa, and the expanded line of the surrounding sea.'

The rest of Tigré may be in general described as a high table-land, consisting of different elevations, which we may consider as interrupted, or, in some cases, rather connected by mountain ranges. From the northern regions of Baharnegash we rise by various steps to the mountain province of Lasta, where the Tacazzé takes its rise, and which here forms the dividing line of the waters that run north-west to the Nile, and those which, taking a south-east course, enter the Indian Ocean, or are lost in the sand. The Samen, on the west of the Tacazzé, forms the high barrier in that direction; and though these mountains rise far above the bed of the river, the latter must have a very considerable elevation, which is indicated by the numerous falls by which its waters descend towards the province of Waldubha. Bruce crossed the Samen by the pass of Lamalmon, which, though very steep in parts, as he describes it, is of much inferior elevation to the southern eminences in the latitude of Antálo. The top is flat and cultivated. Mr. Bruce was fortunate enough to see all at once some people cutting down wheat, and others ploughing, while in the adjoining field there was green corn in the ear, and a little farther it was not an inch above the ground. The mercury stood at $20\frac{7}{8}$ inches, and no dew was experienced after first ascending the mountain, a phenomenon observable in some parts of the United States (in lat. 38°), at an elevation of a few hundred feet. No register of the thermometer being given (Bruce iv. 378), we can only guess the height of Lamalmon, where Bruce crossed it, to be about 9000 feet. In his tables, however, (vol. vii. p. 2,) he gives the height of the barometer on the top of this mountain at 19° 8′ 8″, the thermometer being 42° at night, by which we may estimate the highest point that he attained to be about 11,000 feet. Some of the more southern parts of the ridge are still higher.

Mr. Salt remarks, that in Tigré, properly so called, the soil is sandy, and the rocks rise in vertical strata over schistus and granite[*]. An extensive plain, which stretches westward to the Tacazzé from the hills of Haramat and Agamé, separates Tigré proper from the no less elevated districts of Giralta and Enderta, where the strata are nearer the horizontal direction, and the black mould in the valleys is well adapted for barley, On one of the routes from Adowa to Chelicut the traveller has to ascend on a higher terrace by the steep pass of Atbara, which brings him into Giralta.

The most remarkable characteristics of this country are the hill-forts, or Ambas, as they are called, which often rise with steep sides almost inaccessible, except by a few paths; on the top they sometimes display a level surface of considerable extent. Many of these minor elevations are formed of sandstone lying in horizontal masses, which have been split or worn down vertically, so as to give the whole a castellated appearance. Salt describes Devra Damo, north-east of Adowa, as completely scarped on every side, with one path leading up to it, and in this, as well as in its general appearance, resembling the hill-forts of India. The reader will form a better notion of the aspect of many parts of Abyssinia by looking at Salt's beautiful plates, than by any description. Plate xxi. contains a striking view of the mountains of Samayat, a strong natural post, with two high peaks and a plateau between them. Plate xxii. shows the vale of Calaat, a level plain covered with rich grass, which might pass very well for an English view, except for the precipitous rocks with which it is bounded.

That such a country as Abyssinia should contain prodigious cataracts, seems natural enough; and Mr. Bruce speaks of several that were near, or on his route from, Masuah to Gondar, though from his narrative we infer that he did not see them. The Mai-Lumi, a stream that falls into the Tacazzé, has, according to Bruce, a cascade 150 feet high. The Maisbinni, which joins the Tacazzé on the east side, 'falls in several cataracts near 100 feet high into a narrow valley, through which it makes its way into the Tacazzé.'

---

[*] The obelisks of Axum are all of granite, probably brought from the neighbouring mountains.

We must briefly notice the other approaches to Tigré from the sea-coast. The most southern, leading from Belur, or Belal Bay (N. lat. 13° 14′), is only described by Father Lobo. It leads through Dancáli, and, after quitting the coast, runs along some elevations, till the traveller ascends through a mountain pass into a still higher and cooler region. This is followed by the great salt plain which borders the south-eastern frontier of Tigré, and is more particularly described by Mr. Coffin, who crossed it in 1809, on his route from Amphila Bay to Antálo. From the southern extremity of Amphila Bay (which Mr. Salt, with great probability, conjectures to be the Antiphilus of Strabo), after travelling nearly fifty miles somewhat south of west, Mr. Coffin came to the edge of the flat salt plain, which is said to run from south-east to north-west for four days' journey. The direction of this plain is stated, in Mr. Salt's work, as from north-east to south-west, which Ritter has copied; but this is at variance with Salt's map, and with the general direction of the coast and mountains. It took five hours to cross this plain; and the traveller was provided by the natives with sandals, made of the leaves of the dwarf palm, which are always used in crossing this desert. For about half a mile, the incrustation was slippery and broke under the tread, but afterwards Mr. Coffin found it hard, like a rough, irregular sheet of ice. On the west side he found the Abyssinians cutting out the salt in pieces like a mower's whetstone, which is done with tolerable ease, as it lies in horizontal flakes: the salt near the surface is pure and hard, but that beneath is coarser, and requires some exposure to the air before it is hardened. In some places the salt is three feet deep; but, in general, at the depth of two feet, it is too much mixed with the earth to be fit for use in its native state.

This district supplies all Abyssinia with salt. At the foot of the Senafé, which may be considered as a continuation of the Taranta mountains, a resident Shum, or chief, under the Ras of Tigré, collects, in kind, the tax laid on all salt that comes into the interior, except what is carried on men's backs. This salt, cut into long flat pieces, is one of the principal mediums of exchange in Abyssinia; its value, of course, increasing the farther it is carried westward. 'In the more remote parts of Ethiopia,' says Ludolf, 'you may buy a good mule with two or three bricks of that salt.'

Mr. Coffin, after crossing the Senafé, which is as high as the Taranta, found the seasons changed. He left behind him, on the coast, continued rain and tempests: here he found (16th January) a cloudless sky, and the people busily employed in getting in their harvest.

There is almost, but perhaps not quite, sufficient reason for believing that some part of the range of Samen, which is as high as any land in Tigré or Amhara, reaches the limit of perpetual snow, which, in this latitude, would give a height of about 13,000 feet. Mr. Pearce, on crossing the summit of Ambai-Hai, one of the highest points of the Samen, experienced a heavy fall of snow on the 17th of October; though on his visit to the sources of the Tacazzé, through the mountains of Lasta, on the 4th day of the same month, he does not mention any snow: but, on the other hand, he speaks of snow and ice lying in every hollow of the Amba-Hai, before he had attained the summit. The monument of Adule speaks of snow all the year round on the Samen; but this authority cannot be considered quite decisive. Mr. Salt's testimony to seeing snow on the Amba-Hai from the high land near Adowa (a distance certainly not less than fifty or sixty miles according to his own map), and on the 8th of May, is the strongest testimony that we yet have.

Of the kingdom of Amhara, which Mr. Salt did not visit, our information is neither extensive nor altogether exact. The authorities are the accounts of the Portuguese Jesuits, Poncet, and Mr. Bruce. Amhara is properly the name of one of the southern provinces, which has long been nearly altogether in the hands of the Galla, who have, however, generally adopted the manners of the Abyssinians. Near the centre of the country lies the lake of Dembea, the longest line on which according to Mr. Bruce's map, is about sixty-five English miles; but, as it receives the waters of an immense number of streams, the area of its surface varies considerably between the wet and the dry seasons. Around *this lake*, beginning with the province Begemder, bordering on Lasta, we find—Begemder, Menna, Belessen, Foggora, Dembea, containing the capital Gondar, Tcherkin, Tchelga, Kuara, Maitsha, Gojam, and Damot.

The kingdom of Amhara forms a high table-land, sloping towards Sennaar in the north, towards the Bahr el Abiad on the west, and having on the south-east, in the province of Amhara proper, high mountains connected with those of Lasta. Though we know many names of provinces, subdivisions of provinces, and tribes, our information about the country is exceedingly limited. The parts best known are those near the sources of the Nile, or rather of that branch of the river called the Bahr el Azrek, or Blue River, and the great lake Dembea. According to Bruce's barometer measurements, the height of the sources of the Azrek, which are at some elevation above the level of the lake, must be more than 10,000 feet; but, though this may be much above the truth, there is no doubt that the whole region round the Dembea Lake is a high plateau, in parts intersected by hills. The first account of the springs of the Nile is by Father Peter Paez, from whose unpublished MS. Kircher's account is taken, and this agrees with the account of Gregory, the Abyssinian, which Ludolf had directly from him (A.D. 1657). Paez visited them in 1618. Mr. Bruce visited them in 1770, and puts them in N. lat. 10° 59′ 25″, and E. long. 36° 55′ 30″; giving at the same time a much more minute account of them than that in Kircher, which is not very clear. According to Gregory, the spring-head first shows itself in a certain land, called Secut, on the top of Dengla, which we presume to be an eminence. After a north and north-eastern course of about seventy miles, it enters the lake of Dembea on the west side, having made two cascades of no great height. This lake may possibly be the Pseboa of Strabo. According to Bruce's map, and his journal of the route, this lake receives the waters of a prodigious number of petty streams. There are, according to Ludolf, eleven islands in it: the largest is called Tzana, whence the lake itself sometimes is called *Bahr-Tzana*, or the Sea of Tzana. All these islands, when Ludolf wrote, were possessed by monks.

The hippopotamus is abundant in this lake, but it seems doubtful if the crocodile inhabits it. The Nile, at its exit from the south-east side of the lake, runs south-eastward between Gojam and Begemder, after forming a large cascade at Alata: it then sweeps due south, compassing the land of Gojam with Damot, and leaving Amhara on its left. According to the map, its curve twice intersects the tenth degree of north latitude, and after the second intersection it proceeds in a course about west north-west. The Abyssinian name for the stream is Abawi, which some interpret *Parent*, as if it were the same as the Arabic word *Abou*, father; but this is, at least, doubtful, and those who are disposed to look for Sanskrit roots in the language of this country might connect *Abawi* with the Sanskrit, *Ap*, water. These regions round the lake, situated at so great an elevation above the sea, often enjoy a mild and pleasant climate, which the Portuguese found very like the best temperature of their own country. The seasons are three: the rainy season, from May to the beginning of September, which is that of rest; the summer, or season for the fruits of the earth; and the hot, dry season, which precedes the annual rains. Gondar, the residence of the Negus or Emperor, is north of the Dembea Lake, in N. lat. 12° 35′, E. lon. 37° 33′, and owes much of its present importance to the edifices erected by the Portuguese, the churches and royal castles, which have formed a nucleus for subsequent buildings. Mr. Bruce mentions a bridge with three arches near Gondar, which must be the work of the Portuguese, and another with four arches a little south of the capital. All Amhara was governed by a Ras named Guxo, when Salt was in Tigré, while the king 'lived in almost total neglect with only a few attendants at Gondar.' The warlike viceroys of Tigré and Amhara have, in fact, almost usurped the little authority that remained to the titular kings.

The provinces of Shoa and Efat lie south of Tigré and Amhara: but between Efat and Tigré is the extensive territory of Angot, and probably numerous tribes of which we know nothing. Efat is between the ninth and eleventh degree of latitude, and, if the descriptions are correct, it is intersected by some high land, which forms the line of separation between the streams that join the Nile, and those which run into the Hawash, a river that flows towards Zeila. Two arms of the latter river are described as nearly encircling the country. The chief town is Ankober. Efat is one of the best provinces of Abyssinia, and famed for a good breed of horses. The inhabitants are dexterous horsemen, and good soldiers. Shoa joins Efat on the west, and is well watered by the tributaries of the Nile: it contains fine pastures, large towns, and numerous monasteries. Devra Libanos, or the monastery of Libanos, was once, and perhaps still is, well filled with monks. It also contains the town of Tegulet, once the Abyssinian capital, when these two states, as well as Amhara and Tigré, were included in the empire. Mr. Salt had reason to believe, from the information which he received, that in Efat and Shoa the Ethiopic literature might be found in a purer state, and also more traces of ancient customs might be discovered. These regions are, indeed, a tempting field to the spirit of geographical enterprise, and would probably be accessible, without much risk, by setting out from Zeila on the coast.

The animals of Abyssinia present many varieties, as we might expect in so extensive a country; but those that are peculiar to these regions are all that will require a short notice here. It is only in the lower regions and forests that the monkey and the elephant are found; the latter leaving strong marks of his visits by the damage done to the smaller trees. This animal, together with the rhinoceros, boar, and buffalo, is hunted in Abyssinia; and we have in Bruce's *Travels* (vol. vi. p. 230) a curious account of this African field sport. The elephant is not found on the high terraces of Tigré, which are, indeed, nearly altogether without wood, and consequently not adapted to the habits of this animal. The two-horned rhinoceros, which is supposed to be peculiar to Africa, and is found also at the Cape, is common in Abyssinia, and was known to the Romans in the time of Domitian, as we see from an epigram of Martial; it is also accurately described by Cosmas, a Greek Christian merchant of the sixth century, who had seen it in Ethiopia, both alive and also stuffed with chaff. Its name, as given by Cosmas, is the same as the name by which it is still known—*arwe harisi*. The large-horned ox, called by Salt the Galla ox, is now well known, from his description and drawings · the largest horn that he saw was nearly four feet long, and twenty-one inches in circumference at the base; but the animal itself, contrary to what had been rumoured about it, is smaller than others of the same genus. The savage hyæna (*felis crocuta*) haunts every part of Abyssinia in great numbers, and often makes its way into the towns, to which it is somewhat encouraged by certain superstitious notions of the natives, that prevent them killing it whenever they can. The camel is only used in the lowlands on the coast; and the giraffe is not distinctly mentioned by any traveller as having been seen by him on the terrace lands of Abyssinia, though Mr. Salt seems to say it is found there.—(Appendix, No. 4.)

Mr. Salt speaks of the zebra as being found in the southern provinces; but his notice of it appears too vague to enable us to assign its geographical limits. The buffalo, the lion, various species of leopards (one of which is black), several varieties of the dog kind, and antelopes, are mentioned in Salt's Appendix, to which we refer the reader. Mr. Salt also mentions an undescribed species of lemur, with a clear white skin, adorned with a single black oval spot on its back. These skins come from Damot and Gojam, and are an article of trade. The ostrich is not found within the limits of Abyssinia Proper, which is not a country adapted to this bird's habits. Mr. Salt mentions that there are many species of falcons in Abyssinia; that vultures are numerous; and that the Egyptian goose is sometimes met with. Game, such as red-legged partridges, Guinea fowls, quails, snipes, and doves, is common all through the country. In Mr. Salt's Appendix will be found a list of the rarer birds which he collected in Tigré.

Among the insects, the locust is the only one described by Salt, being that species which is said occasionally to commit those dreadful ravages in Abyssinia, briefly described by Ludolf. Bruce speaks of a black ant, nearly an inch long, which cut his carpets in shreds, and thus proved its relationship, in mischief at least, to the white ant of India.

It does not fall within our plan to give any account of the vegetable productions of Abyssinia; those which are most worthy of notice will be found in their proper places. As an object of picturesque beauty, the daroo tree (*ficus sycamórus*), as we see it represented in Salt's view of the Obelisk of Axum, and in other drawings, must add materially to the appearance of the country. The grape we believe to be indigenous in Abyssinia, and in some parts tolerable wine is made. The jessamine, both orange and white, and yellow like that of Virginia; and a honeysuckle, resembling that of England, are plentiful in some parts. The caper-tree, says Bruce, grows as tall as an elm, and with a white flower, and a fruit as large as an apricot. After crossing the Tacazzé in N. lat. 13° 42′, he speaks of lemons and citrons. growing wild in the woods, which he seems to consider as indigenous, and not introduced by the Portuguese. He adds, that a branch of the Tacazzé is called Mai-Lumi, which he interprets the 'river of limes or lemons;' which has, to us, rather an apocryphal appearance. Bruce saw many fine orange-trees near Gondar, but he says that the only 'benefit expected from them is the shade.' The lemon-trees on the Mai-Lumi were full of good fruit, but the natives made no use of it.

That the Abyssinians are, even in their present state, somewhat superior to most African nations, will appear from the following list of articles manufactured among them:—Small carpets, from Samen, of good quality; parchment, from Axum; and iron and brass articles: but the best specimens of brass chains are brought from the south, where they are said to be manufactured among the Galla. 'Hides,' says Mr. Bruce, 'are tanned to great perfection in Tigré.' The Abyssinian saddle, as described by Mr. Salt, and the whole accoutrements of their horses, are good. The horses themselves are generally strong, well made, and kept in good condition; and the men themselves are excellent horsemen. They use long stirrups.

Of the manners of the Abyssinians of Gondar we have an elaborate picture by Bruce, which we believe to be heightened with the usual colouring of that traveller. In his eleventh chapter he describes a feast of the higher classes, in which a cow or bull is brought to the door; the feet are tied; the skin is stripped off the hind quarters; and the flesh is cut from the buttocks in solid square pieces. 'The prodigious noise the animal makes,' adds Mr. Bruce, with the most comical gravity, 'is a signal for the company to sit down to table.' The licentious termination of the feast exceeds anything that we know of the most barbarous nations of the earth, and may at least be doubted until it is confirmed. As to the Abyssinians eating raw flesh occasionally, or even frequently, *that* does not appear to us to be by any means beyond the reach of probability; and, indeed, we find Mr. Pearce (see Salt, p. 295) corroborating the fact so far as this—that some brutal Lasta soldiers, on a marauding expedition, while driving a cow, cut two steaks from the rump, which they devoured raw, to satisfy their craving hunger. The animal was then driven on to the camp, and killed. But Mr. Pearce, who had been several years in Tigré, never heard of such feasts as Bruce describes. Mr. Salt, when he was in Abyssinia, met with a learned doctor from Gondar, who had known Bruce, and spoke favourably of him. The feast story, however, was more than he would admit, and he expressed great abhorrence at the thought of it. At the same time he allowed that the licentiousness of the higher orders was carried much further in the kingdom of Amhara than in Tigré. Yet Mr. Sait met with many young men at Chelicut, who came from Gondar, whose dress and manners created a very favourable impression; and he says, 'I have reason to believe that, in general, the people of Tigré are much ruder in their habits and fiercer in disposition than those of Amhara.' The prince Kasimai Yasous, who was at Chelicut on a visit from Gondar, had superior accomplishments to most of the young men in the country, and could both read and write the Geez with great facility.

The early Portuguese writers allow the people of Narea the first rank among the Abyssinians for good manners, while their account of the people of Tigré was unfavourable, and in accordance with that of Mr. Salt. Yet this traveller lived three weeks at Chelicut, saw the Ras daily, and was often invited to his evening repasts, without either seeing or hearing of any of the indecencies and grossness which Mr. Bruce describes: intoxication, however, is common at feasts. The Abyssinian is in general well made, and sometimes handsome, with features completely Roman. Those of Narea are described as not darker than the Southern Europeans, but the people of Abyssinia in general are nearly black. They must not, however, be confounded with the negro tribes, as they have neither the nose, lips, nor hair that characterize the people of Western Africa. It is true that some of those whom Bruce saw on the Taranta had curly heads and short hair; but this is done by art, 'each man having a wooden stick with which he lays hold of the lock, and twists it round a screw, till it curls in the form he desires.' Mr. Salt saw, on one occasion, the Ras's wife, who was the sister of the Emperor, and he describes 'her form as elegant, though small; her features were regular; and, having fine teeth and coal-black hair, she might, in any country, have been esteemed handsome.'

Though the Abyssinians form a nation with a physical character that distinguishes them from other nations, yet the country contains some people of a different stock, such as the Christian Agows, who live along the east bank of the Tacazzé from Lasta to the confines of Shiré. It is said they were once Nile worshippers, and were converted in the seventeenth century to the Christian religion. There are also Agows, who are still Nile worshippers, about the sources of the Nile, who supply Gondar with cattle, honey, butter, wheat, hides, and wax. Bruce describes more particularly those who live near the sources of the river at Geesh. The high-priest of the Nile was a venerable old man with a white beard, seventy years of age, and blessed with a family of eighty-four or eighty-five children. The Geesh people never wash themselves or their clothes in the water that comes from the three genuine sources of the Nile, but in other streams tributary to that sacred river. The Waito, who live on the east bank of the Great Lake, are described by Bruce as speaking a language radically different from all others in Abyssinia: they feed on the hippopotamus, and are filthy and ill-looking.

The mountains of Samen, according to Bruce, are nearly occupied by Jews, otherwise called Falajas (a word signifying strangers), in which he agrees with Tellez, who says, 'the Falaxas, or Jews, occupy the strongest and highest points of the Samen; they are warlike, and have done much damage to the neighbouring provinces.' Tellez adds, that they still possess the Hebrew Scriptures, and chant the Psalms in their Synagogues. The Shangalla negroes, we are informed by Bruce, are very numerous in Gondar, where they are slaves; they are also used as slaves in Tigré. A more particular account of them, as well as of the Galla, those troublesome enemies of the Abyssinians, will be found under their respective heads. The state of slavery in Abyssinia is an improved condition for the poor Shangalla, for they escape numerous evils incident to their wild state, and are well treated.

The Abyssinians even now are not without authors. Mr. Salt brought to England a manuscript, containing an account of the Ras's last campaign against the Galla, which the Ras himself made a present of to Mr. Salt. The history was written by a court scribe, in a style very complimentary to his master. The Ras had a jester at court, whose powers of mimicry, and even of regular acting, were of a very high order. A painter was also in his service; and Mr. Salt has given (p. 394) an outline of one of his subjects, representing a combat between some mounted Abyssinians and Galla, which conveys rather a favourable impression of this artist's skill. The Abyssinians are generally fond of pictures, with which they line the inside of their churches and decorate their chief apartments, when they can procure them.

In our present state of knowledge it is not possible to attempt any complete classification either of the peoples or languages included within the limits of Abyssinia. There is no doubt that the varieties of language are very numerous. The chief tongue is the Geez, sometimes called the Ethiopic, in which the Scriptures are written. The spoken language of Tigré is a dialect of the Geez, which, in the course of time, has undergone considerable changes. The Geez is said, by Ludolf, to approach most nearly to the Arabic; and as we are unable ourselves to form a judgment on this matter, we shall quote the words of this distinguished scholar—'It approaches nearest to the Arabic, of which it seems to be a kind of production, as being comprehended almost within the same grammatical rules, the same forms of conjugations, the same forms of plurals both entire and anomalous; so that whoever understands either that or the rest of the Oriental languages, may, with little labour, understand this our Ethiopic.' The Amharic, now the spoken language of a large part of the kingdom of Amhara, is said, by Ludolf, to differ considerably from the Ethiopic in construction and grammar, yet, he says, 'for above half the language, as far as I can judge, the words are common to both.' From the list of Amharic and Tigré words given in Salt's Appendix I., it appears that these two languages do differ considerably, and yet they agree in the numerals (as far as examples are given), nearly altogether, which is a strong proof of an original close relationship. The Amharic language, according to Bruce, is now very widely diffused. Its alphabet is the same as the Geez, with seven additional characters to represent the compound Amharic consonants the origin of this alphabet is not known, though Mr. Murray asserts it to be derived from the Greek. (See article ETHIOPIA.) In Bruce's work, vol. ii. p. 416, the reader may see an account of the MSS. which that traveller brought from Abyssinia. We have purposely refrained from attempting any sketch of Abyssinian history, as it would lead us far beyond all reasonable limits.

The reader may consult, for further information, *Salt's Abyssinia*, 4to. 1814 — *Valentia's Travels* — *Bruce's Travels*, 7 vols. 8vo.—*Ludolf's History of Ethiopia*, translated, London, 1682—*Tellez, Historia Geral de Ethiopia*, &c., Coimbra, 1660; a copy in the British Museum—*Ritter's Africa*.

ABYSSINIAN CHRISTIANS.—The discovery of a body of Christians in so remote a country excited, in no small degree, the attention of Europe in the fifteenth century, which has been again revived by Salt's last mission, in 1810. From the "Tareek Negushti," or, "Chronicle of the Abyssinian Kings," combined with the evidence of the ecclesiastical writers, we learn that Christianity was introduced into Abyssinia in the time of Constantine, by Frumentius, or Fremonatos, as the chronicles call him. Frumentius, after residing some years in the country, was raised by Athanasius the patriarch of Alexandria, to the dignity of bishop. He arrived in Abyssinia, perhaps about the year A.D. 330, and probably in the reign of the King Aizanas, whose name still exists on the inscription of Axum. It is, however, not certain to which king of the Abyssinian chronicles we ought to apply the names of Aizanas and his brothor Saizanas, both of which occur on the inscription, and also in a letter of the Emperor Constantine, addressed to them A.D. 356. When the Greek merchant Cosmas visited Abyssinia, A.D 525, it was completely a Christian country, and well provided both with ministers and churches. Of the Abyssinian churches, which probably belong to the earlier periods of their conversion, or at least are eight or nine hundred years old, there are still some remains. The most remarkable is Abuhasubha, hewn out of the solid rock, which at this place is soft and easily worked. The Portuguese, Alvariz, describes ten such churches as these, of which he has given a plan, and one of them is probably the same as that which Mr. Pearce visited at Jummada Mariam. (Salt, p. 302.) The great church at Axum is comparatively modern, though parts of it, such as the steps, clearly belong to a prior edifice. Mr. Salt describes the well-built remains of a church, or monastery near Yahee, which he assigns to the sixth century of the Christian era.

The monastic, and also the solitary life, spread into Abyssinia from the deserts of the Thebais, and when the Portuguese Jesuits entered the country they found it full of such devotees; many of them seemed, however, to be monks only as far as celibacy was concerned, for they cultivated the ground and lived in villages.

Though a king of Abyssinia, Zarah Jacob, in 1445, sent an ambassador to the council of Florence, very little was known of the country until the Portuguese entered it. We cannot undertake to explain exactly how the notion of an Asiatic Christian prince residing in India, under the name of Prester John, got abroad; those who are curious may consult Ludolf (book ii. c. 1.) and the first chapter of the second book of Tellez. However this may be, John II. of Portugal, anxious to follow up the Portuguese schemes of discovery, and to discover the true Prester John, sent Peter Covilham and Alfonso Payva to find him out wherever he was. These envoys are said to have gone as far as India, but without success, and Payva returned home. Covilham, however, happening to be in some port of the Red Sea, heard of a Christian prince of the Abessines, whom he forthwith concluded must be the object of his search, and accordingly this enterprising man succeeded in reaching (A.D. 1490) the court of the Negus, or King of Abyssinia, which was then in Shoa. This was the beginning of that connexion between the Abyssinians and the Portuguese, which continued for about one hundred and fourteen years; but during this long period the missionaries had one leading idea, which was to bring over the Abyssinians to the Catholic faith. Peter Paez, who entered the country in 1603, actually prevailed on the Emperor, his brother, and the nobles, publicly to declare their adhesion to the Church of Rome.

Though the Jesuits pursued their proselyting practice with such pertinacity, they did not neglect to study the country itself, and, accordingly, it is to them that we owe our first accounts of many parts of Abyssinia; and for some, they are yet the only authorities. A list of the principal works of the Portuguese on Abyssinia is given by Salt, and the reader will see, in the compilation of Ludolf, and the abridgment of Tellez, how much we are indebted to these zealous and often very able men.

With the Christian religion, the Abyssinians received the Holy Scriptures, which they now possess in the ancient Ethiopic version, made, according to Ludolf, from the Greek Septuagint, though nothing is known of the date of this version. As to the New Testament, (says Ludolf,) no entire copy has been yet brought to Europe. Mr. Bruce brought with him from Abyssinia a complete copy of the Scriptures in the Ethiopic language, and also a set of the Abyssinian Chronicles. The Abyssinians divide the Scriptures, which they have entire, differently from what we do, making four principal parts of the Old Testament, and mixing what we call the Canonical with the Apocryphal books. The New Testament is also divided into four parts, to which they add the Book of Revelations as a supplement. For other information respecting the Abyssinian liturgies, and the religious opinions of the Abyssinians, we refer to Ludolf, Book iii. chap. 4, 5. Ludolf denies the existence of the book of Enoch, because he had only seen a spurious copy. A knave who got possession of an Ethiopic book, wrote the name of Enoch upon it, and sold it to Peiresc for a considerable sum of money, and this was the book that Ludolf saw. Bruce brought home three copies of the book of Enoch; one of which he gave to the Bodleian Library at Oxford. This book was originally written in Greek, but the original is lost—all but one large fragment. In the epistle of Jude reference is made to the prophecies of Enoch; and Mr. Bruce says, 'the quotation is word for word the same in the second chapter of the book.' This, however, will not prove the genuineness of the prophecies of Enoch, as Mr. Bruce has very well argued. An English translation of the book of Enoch was published by Dr. Lawrence, Oxford, 1822, 8vo.

The High Priest (or sole bishop) of Abyssinia is called *Abuna*, which signifies Our Father; and as Frumentius, the first bishop, received his appointment from the Patriarch of Alexandria, this dignitary has, probably, always been a foreigner. When Mr. Salt was in Abyssinia (1810), the Patriarch of Alexandria had just sent a Greek as Abuna, or High Priest, who, unfortunately, died of an epidemic disorder soon after his arrival. His followers were going back to Alexandria to see if they could get a new one appointed. The King is the head of the Church. Polygamy, though not allowed by the ecclesiastical canon, is common enough in practice; and Mr. Salt mentions an instance of one gentleman who had five wives at once. The king, of course, marries as many as he pleases: the clergy, also, who are not monks, may marry, but only once. A second marriage renders them unworthy of their sacred office, according to the ancient canons. Circumcision, according to Bruce, is practised in Abyssinia.

It would appear, from what we know of the Abyssinian Church, that its priests, at present, are not well informed, nor are the people in general well acquainted with the principles of the Christian religion, though they may be Christians in name; yet some of their ceremonies are conducted with great decency, and very much resemble those of the Church of England. When Mr. Salt stood godfather to a boy who was baptized into the Christian faith, after naming the child—George, he was requested to say the Belief and Lord's Prayer, and 'to make much the same promises as those required by our own Church.' The head priest then crossed the boy on the forehead, after dipping his hand into the water, and pronounced, 'George, I baptize thee in the name of the Father, Son, and Holy Ghost.'

When Salt was at Chelicut, Lent was strictly observed for fifty-two days, and no flesh was eaten during this period, though fish and various dishes were always plentiful on the table: the people always fasted till sunset. A feast followed this severe and protracted fast, in which they all seemed anxious to make up for lost time, by over-eating and drinking.

The Sacrament is also administered in Abyssinia, in a very decorous manner; and red-wine made of a grape, which is common in some parts of the country, is used on the occasion. Formerly, (says Mr. Salt,) if a man married more than one wife, he was excluded from participating in this rite, but wealth and power have induced the Church to relax its severity in this respect. Marriage itself, in Tigré, appears a mere civil institution: the woman keeps her name, and the parties can separate whenever they agree to do so. In this case the woman has her dowry back, which is not forfeited unless she is manifestly guilty of adultery. The higher classes are subject to no rule, but what may be considered as imposed by the relatives of the male and female. The Abyssinians bury their dead immediately after washing and fumigating the body with incense: while the bearers are putting it in the ground, the priests recite a form of prayer. Other strange ceremonies that follow are described by Salt. —*Ludolf's History of Ethiopia.—Bruce*, vol. ii. p. 422.—*Salt's Abyssinia.*

ACA'CIA-TREE. See Robinia.

ACA'CIA, the name of a plant of the pea-tribe, mentioned by Dioscorides, as a useful astringent thorn, yielding a white transparent gum. The account given by this Greek author, meagre as it is, accords so well with the gum-arabic trees of modern Egypt, that we can scarcely doubt their identity. Accordingly it is to these, and to others closely related to them, that the classical name is still applied.

Among the moderns, the Acacia is a very extensive genus of trees or shrubby plants, inhabiting the tropical parts of both the Old and New World, and, in a very few instances only, extending into temperate latitudes; although over the whole of Australia, and its dependent islands, the species are spread in much abundance.

Some of the species produce catechu and gum-arabic; the bark of others yields a large quantity of tannin, which, in the form of an extract, is annually imported from Van Diemen's Land in considerable quantity; the species from which this substance is procured are chiefly *A. decurrens* and *mollissima*. As objects of ornament they are usually of striking beauty; and it may be doubted whether, in the whole vegetable kingdom, equally brilliant colouring, and elegant foliage, combined with a most graceful aspect, are united in the same individuals.

Botanists are acquainted with nearly 300 species. Of these we shall mention only a few of the most interesting.

Generic Character.

Flowers polygamous.

Calyx, with either four or five teeth.

Petals, either four or five; sometimes distinct from each other, sometimes adhering in a monopetalous corolla.

Stamens varying in number from 10 to 200.

Pod not separating into many joints; juiceless, two-valved.

The species are extremely variable in the structure of their leaves and flowers. Some of them have true leaves that are twice or thrice pinnate, with a multitude of minute, shining, or at least even, leaflets; others have, in a perfect state, no leaves properly so called, but, in their stead, the leaf-stalks enlarge, and assume the appearance, and no doubt also the functions, of true leaves: species of the latter description are known by their spurious leaves being expanded vertically, instead of horizontally as in leaves of the ordinary construction. By these very remarkable points of difference in structure the species may be conveniently separated into two great subdivisions.

§ 1. *Leaves pinnated in various degrees.* About 200 species known.

Acacia Catechu. The catechu acacia. (*Willd. Sp. pl.* iv. 1097. Mimosa catechu, *Linn.*) Spines growing in the place of the stipulæ; when young, straight, but afterwards becoming hooked. Leaves in ten divisions; leaflets in from forty to fifty couples, linear, downy; with one depressed gland at the base of the leaf-stalk, and from two to three between the upper divisions. Flowers arranged in cylindrical spikes, which grow two or three together.—A tree with a tolerably high and stout stem; found in mountainous places in the East Indies, especially in Bengal and Coromandel. It is most common in Canara and Bahar. Its pods are from two to three inches long, quite flat, and of a narrow, oval figure. Its unripe pods and wood yield, by decoction, one of the sorts of catechu, or terra-japonica, of the shops, a powerfully astringent substance, formerly thought to be a kind of earth. The other sort of catechu is obtained from a kind of palm. [See Areca.]

[Acacia Catechu.]

Acacia Arabica, the gum-arabic tree. (*Roxb. Coromand. Plants*, 149.) Spines growing in pairs. Branches and leaf-stalks downy. Leaves in from four to six divisions; leaflets in from ten to twenty couples oblong-linear, with a gland between the lowest, and often between the outermost divisions. Heads of flowers growing in threes upon stalks. Pod necklace-shaped.—An inhabitant of the East Indies, Arabia, and Abyssinia, where it forms a tree thirteen or fourteen feet high, of inelegant appearance; easily recognised by its long, curved pods, which are divided into a number of round compressed joints, by means of contractions between the seeds. This is one of the plants that yield the useful substance called gum-arabic, which is procured by wounding the bark; after which the sap runs out, and hardens in transparent lumps, of various figures, very similar to the concretions found upon the bark of the cherry-tree in this country. Gum-arabic is also produced abundantly by some of the species nearly related to this, such as *A. Nilotica*, or *vera*, found in Egypt; *A. Ehrenbergii*, a native of Dongola; *A. tortilis*, a common plant in the west of Nubia, Kordofan, and Arabia, especially upon Mount Sinai; and *A. Seyal*, an inhabitant of Upper Egypt, Nubia, and western Arabia. It is supposed that gum-arabic is collected indifferently from all these, and that the gums of Jidda and Bassorah, gum-thur, and East India gum, are only picked samples. Gum-Senegal is the produce of a distinct species, called *A. Senegal*, found in Arabia and the interior of Africa. From this tree are said, by some, to be procured the pods called *bablach*, in the continental drug-shops; by others, however, they are referred rather to *A. cineraria*, and some other species.

[Acacia Arabica.]

Acacia discolor, the purple-stemmed acacia. (*De Cand. Prodr.* ii. 468. Mimosa discolor, *Bot. Rep.*) Spines none. Leaves with about five pairs of pinnæ; leaflets glaucous, tinged with purple, in from nine to twelve couples, oblong, smooth, acute, pale beneath; leaf-stalks glandular at the lower end, and covered with down, like the branches. Heads of flowers in long racemes, proceeding from the axillæ of the leaves.—A middle-sized tree, found in the southern parts of New Holland and in Van Diemen's Land, where it, in common with many others of the same genus, is called *Wattle*. It appears better adapted than most other Australian species to support our winters; near London it succeeds perfectly well, all winter long, in the open air, if wrapped round with mats, and it is to be presumed that there is no obstacle to its being almost naturalized in Devonshire and Cornwall and the west of Ireland. It is readily known by its bluish stems and leaves, which are slightly stained with dull purple, and form a strong contrast with its long, erect bunches of yellow blossoms.

Acacia pubescens, downy acacia. (*Hort. Kew.* v. 467.) Spines none. Branches not angular, hairy. Leaves with from three to ten pairs of pinnæ; leaflets in from six to eighteen couples, linear, very narrow. Heads of flowers globose, stalked, arranged in long racemes.—A native of the east coast of New Holland. In this country it is one of the most beautiful of green-house plants; if allowed to grow freely in the border of a good conservatory, it attains the height of ten or twelve feet; and in January and February produces a vast abundance of yellow blossoms, which weigh down the slender graceful branches, and perfume the air with a weak but pleasant odour.

Acacia Julibrissin, silk-tassel acacia. (*Willd. Sp. pl.* iv 1065. Mimosa Julibrissin, *Scopoli.*) Spines none. Leaves with from eight to twelve pairs of pinnæ; leaflets in about thirty couples, half-oblong, acute, somewhat fringed, with a flattened roundish gland at the base of the leaf-stalk. Heads of flowers on stalks, arranged in a sort of corymbose panicle at the end of the shoots. Pods flat, membranous, smooth.—A native of Persia and of the Levant. Its specific name is Latinised from two Persian words—*gul*, a rose; and *ebruschim*, silk; by which it is known in the countries where it grows wild. There it becomes a small tree, remarkable for its light airy foliage, and for the great beauty of the clusters of lilac flowers, the long and slender stamens of which stream in the wind, and glitter in the sun, like a number of silken tassels artificially fastened to the boughs. This species is now commonly cultivated in the warmer parts of Europe. In England it is seen trained against walls, where it succeeds indifferently well, flowering only occasionally so far north as the latitude of London. Its great enemy in this climate seems to be, not our winters, but the want of an intensely hot summer to prevent exuberant growth, and to ripen the shoots so perfectly, as to enable them to resist frost.

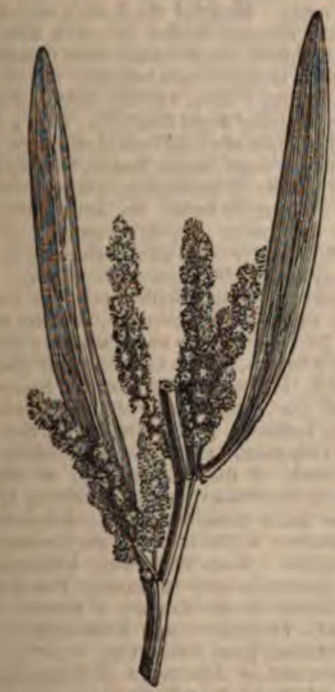
Acacia acanthocarpa, prickly-fruited acacia. (*Willd. Enum.* 1057.) Spines from the place of the stipulæ, growing in pairs, and hooked. Leaf-stalks without either prickles or glands; leaves in from six to eight principal divisions; leaflets in from six to fifteen couples, oblong, downy. Heads of flowers in pairs, stalked. Pods compressed, plane, falcate, with each margin prickly.—A native of New Spain, where it forms a small tree, with flesh-coloured flowers. It was some years since introduced to the gardens of France, in the southern provinces of which it proves hardy. In this country it is not so capable of resisting frost as *A. Julibrissin*, or some of the New Holland species, notwithstanding it is marked as hardy in some of our garden catalogues. As its flowers have little beauty, it is very seldom cultivated.

The *Black-wood* of Van Diemen's Land is the timber of *acacia melanoxylon;* and the astringent *jurema bark* of Brazil is the produce of *acacia jurema.*

§ 2. *Leaves pinnated in the young plant; in the old, consisting of nothing but the vertically distended leaf-stalks, called* PHYLLODIA. About 100 species.

Acacia decipiens, paradoxical acacia. (*Hort. Kew.* v. 465. Mimosa decipiens, *Bot. Magaz.* t. 1745. Adiantum truncatum, *Burm. Fl. Ind.* t. 66. f. 4.) Stipulæ spiny, deciduous. Phyllodia either triangular or trapezoidal; their midrib nearest the lowest side, and lengthened into a spine; a single glandular tooth on the upper edge. Flowers in nearly solitary compound heads.—This species is remarkable for the blunders to which it has given rise. When botany was only a science of names, its flowerless branches were taken for the leaves of a kind of fern; and, at a later period, when botanical geography was as yet unheard of, it was believed to be a native of the north-west coast of North America; an opinion as probable as that would now be considered which referred the origin of a race of blackamoors to Great Britain. It is an inhabitant of the south-west coast of New Holland, where it forms a bush of singular aspect. In this country it is cultivated in the green-house, and it flowers in March, April, and May.

Acacia Sophoræ, fragrant acacia, (*Hort. Kew.* v. 462; *Labill. Nov. Holl.* 2 t. 237.) Phyllodia narrow, tapering towards the base, quite entire, with one principal midrib; an oval gland on their upper edge near the stalk. Heads of flowers in dense slender racemes. Pods long, curved, taper-pointed, a little contracted between the seeds.—A native of the south side of New Holland and Van Diemen's Land. In this country it is a very ornamental green-house plant, which, if planted in the open border, will grow as high as eight feet. It flowers during all the early months of the year; producing its numerous clusters of sweet yellow blossoms in great profusion. Few plants are more worthy of a permanent station in a good conservatory.



[Fragrant Acacia.]

Acacia longifolia, long-leaved acacia, (*Willd. Sp. pl.* iv. 1050. Mimosa longifolia, *Bot. Reposit.*, t. 107.) Phyllodia of a narrow, lanceolate form, tapering to each end, with two or three strong veins at the base, and several in the upper part. Spikes of flowers axillary, growing in pairs, on short stalks.—Found very commonly on the eastern coast of New Holland, especially in the neighbourhood of Port Jackson, whence it was introduced into Great Britain, among the first of the natural productions of that remarkable country. It is not sufficiently hardy to bear the open air in this climate, except in the summer, and should be cultivated in the open border of a conservatory, if we wish to have it in perfection. So treated, it is a very elegant plant, growing twelve or fifteen feet high, and bearing large masses of fragrant yellow flowers, in the months of March, April, and May.

Cultivation. The species of this genus are increased artificially in two different ways. Most of them may be multiplied by cuttings struck in silver sand, placed under a bell-glass, and kept in a warm place, to which no direct solar light has access. Such of them, however, as do not increase with sufficient certainty by this method, *A. Julibrissin* for instance, have the power of producing shoots from pieces of their root placed in earth in a hot-bed; and by these the nurserymen generally propagate them. Their seeds, also, are very often received, and from these they can, of course, be multiplied in all cases.

ACADEMY. A house and garden in one of the suburbs of Athens, inclosed by a wall, and having the grounds laid out in walks shaded by trees, was the original Academy. It is commonly stated to have been so called from its original possessor Academus, or Ecademus, who is said to have established here a school of gymnastic exercises. Other etymologies of the term, however, have also been given. About the middle of the fifth century before the commencement of our era, the groves of Academus fell into the possession of Cimon, the Athenian general; and it was he who first adorned the place with statues and fountains, and added other improvements, so as to convert it into a retreat uniting to the charms of natural scenery many of the luxuries of art. At his death he left the garden to the public; and it became a favourite resort of the lovers of philosophy and solitary meditation. Hither Socrates was wont occasionally to repair to converse with his disciples. But it was his illustrious pupil, Plato, who first gave celebrity to the Academy as a seat of philosophy, by establishing here the school over which he presided for nearly half a century. Hence the Platonic philosophy is frequently called Academism, or the philosophy of the Academy; and its followers, Academics, or Academists. Plato died about the year 348 before the Christian era. About the year B. C. 296, one of his successors, Arcesilaus, introduced certain changes into the original doctrines of the school; and he is on this account considered the founder of a second, or Middle, as distinguished from the Old academy. There was also in this sense a third academy, called the New, of which the founder was Carneades, who flourished about a century after Arcesilaus. Some writers even reckon a fourth Platonic academy, founded soon after the time of Carneades, by Philo (not the celebrated Platonic Jew), and Charmidas or Charmadas; and a fifth, designated the Antiochian, from its founder Antiochus, who had been a disciple of Philo. The opinions of these different schools will be explained under the heads PLATO, ARCESILAUS, &c. With regard to the academy of Plato, we may further notice that it was situated in the suburb, lying to the north-west of Athens, called Ceramicus, that is, literally, the Place of Tiles; and it has been remarked, as a curious coincidence, that the principal public garden of that city should thus have apparently had the same origin with the *Tuileries* of the modern capital of France, a name which also indicates that the site was anciently that of a tile-work. Cicero had a country seat on the Neapolitan coast, to which, as one of his favourite retreats for philosophical study and converse, he gave, in memory of the famous Athenian school, the name of Academia. It was here he wrote his Academic Questions. Its remains are still pointed out near Pozzuoli, under the name of the Bagni de' Trìtoli.

After the restoration of letters in the fifteenth century, the term Academy was revived in Italy, but with a signification somewhat different from what it had borne in ancient times. It was used to imply, not a school in which philosophy was taught by a master to his pupils, but an association of individuals formed for the cultivation of learning or science, and usually constituted and endowed by the head of the state in which it was established. What was now called an academy, in fact more nearly resembled what was anciently denominated a Museum,—the name given, for example, to the famous association of the learned, founded by the first Ptolemy, at Alexandria, which so long subsisted in that city. The emperor Charlemagne is also recorded, towards the close of the eighth century, to have established in his palace at Paris a society of this description. It was the fancy of the members of this society to assume each a classical or scriptural appellation. At their meetings they were accustomed to give accounts of such books as they had been studying; and their attention is said to have been also directed, not without effect, to the regulation and improvement of the vernacular language of the country. This association, however, existed only for a few years; and it does not seem to have been imitated elsewhere. Charlemagne was also the founder of the University of Paris, and several other schools and seminaries of instruction; but although the Greek term Academia has often, at least in more recent times, been applied to such institutions, they are altogether distinct in their nature from what is properly called an academy, and they will, therefore, be more appropriately and conveniently considered under the terms *University*, *College*, *Gymnasium*, *School*, according to the names by which they have been severally distinguished, than under our present head. On this point it is only necessary further to remark, that, from the application just noticed of the Greek term, it has of late become common, more especially in England and the United States of America, to give the name of academies to those seminaries in which so many various branches of education are taught as to entitle them to rank, it may be thought, as a sort of minor universities. In this sense, many of the principal towns in Scotland have their academies, which are merely great schools, such as in Germany would be called gymnasia, embracing in some cases both the languages and the sciences, but in general confined chiefly to the latter. In England, again, the colleges of the dissenters are commonly called academies; and the name is also frequently assumed by mere private boarding-houses, on however small a scale. The government institution at Woolwich for the instruction of military cadets is called the Royal Military Academy. It was founded in 1741, and is under the direction of the Board of Ordnance. There is also a Royal Naval Academy at Portsmouth, founded in 1722, under the direction of the Board of Admiralty. The Jewish seminaries for the highest branches of learning, in the different countries of Europe, have usually borne the name of academies. The same name has long been applied to schools of riding, of dancing, and of gymnastic exercises.

On the other hand, many of those associations of the learned, which, in all material respects, resemble the academies that arose in Italy with the revival of letters, are, nevertheless, not known by that name. They are called not academies, but *societies*, *associations*, *museums*, *lycæums*, *athenæums*, *institutes*, &c. If these different bodies were generally connected as parts of a great whole, it might be desirable, notwithstanding this perplexing diversity of appellations, to review them all in the same article; but they are not, in fact, related either as ramifications from a common stem, or by any other principle uniting them into one community; and we shall therefore adopt the plan most convenient for the purposes of reference, of only noticing, under our present head, those of them that are designated academies, and distributing the rest under the other titles by which they happen to be distinguished.

I. ITALIAN ACADEMIES.—Italy, as we have said, was the first country in which literary and scientific academies were established on the modern form, and there they have always flourished in the greatest number. A writer of the name of Jarckius, who, in 1725, published at Leipzig an account of the Italian academies, enumerates nearly 600 as then existing. Scarcely a town is to be found without such an institution, and most of the principal cities have ten or twenty, or more. We shall notice a few of those that have been most celebrated. The first that deserves to be mentioned is the Platonic Academy, established at Florence about 1474, by Lorenzo de' Medici. Its principal object was the study of the works of Plato, to which were afterwards joined the improvement of the Italian tongue, and the perusal and explanation of the poetry of Dante. Marsilius Ficinus, Picus Mirandola, Machiavel, Angelo Politian, and other persons remarkable for learning and genius, were among the early members of this association. The civil troubles of Florence occasioned the dispersion of its members in 1521. In 1560 was established at Naples, the first association for the cultivation of physical science, and the origin and model of many others in different countries of Europe, under the name of the Academia Secretorum Naturæ. It was, however, soon after abolished by the ecclesiastical authorities. To it succeeded the Academia dei Lyncei, founded at Rome, in 1609, by Prince Cesi, of which Galileo was a member. Prince Cesi died in 1632, and soon after the Academy was dissolved. Another of the same name was established at Rome in 1784, which still exists. But the most celebrated of the Italian academies is that named the Academy *della Crusca*, that is, literally, *of the Bran*, or *Chaff*, in allusion to the object of its institution, the purifying of the national tongue, and the sifting, as it were, of its flour from the bran. It was established at Florence in 1582, principally by the exertions of the poet Antonio Francesco Grazzini, who is much celebrated for the purity of his style. The Dictionary of the Academy *della Crusca*, first published under the title of *Vocabolario degli Academici della Crusca*, at Venice, in 1 vol. folio, in 1612; but augmented, in the last edition (Florence, 1729—1738), to 6 vols. folio, is considered as the standard authority for the Italian language; and the writers from whose works it has been collected, or whom it recognizes as classics, such as Boccaccio, Machiavel, &c., are hence frequently denominated *Autori Cruscanti*. The Academy *della Crusca* is now incorporated with two still older societies, the Academia degli Apatici, (or Academy of the Impartials,) and the Academia Fiorentina, originally the Academia degli Umidi, founded in 1549 by Cosmo I. The united institutions bear the name of the Royal Florentine Academy. Another very famous old Florentine academy is that entitled *Del Cimento*, that is, the *Academy of Experiment*. It was instituted for the cultivation of physical science, by the Cardinal Leopold de' Medici, brother of the Grand Duke Ferdinand II., in 1657. Among its first members were Borelli, Viviani, &c. A collection of experiments on the pressure of the air, the compressibility of water, on heat, sound, projectiles, light, and other subjects belonging to natural philosophy, was published in Italian by the Academy del Cimento in 1667, of which Muschenbroeck afterwards gave to the world a Latin translation, with valuable notes. Many of the Italian academies are remarkable for the fantastic names by which they are designated. Of this, indeed, the Academy della Crusca is itself an example. And it seems to have borrowed the idea of its title, and also of its device, a sieve, with the motto, '*Il più bel fior ne coglie*,' (It collects the finest flour of it,) from a previous society, established, soon after the revival of letters, at Perugia, called the Academy degli Scossi, that is, the Academy of the Well-shaken; by way of intimating, it is said, that the mind requires to be thoroughly tossed up, and shaken free of its refuse, before its powers can be properly exerted. The emblem of this society was also a sieve, with the Latin motto, *Excussa nitescit* (Shaken out it shines). There was another academy at Perugia, with which this became eventually united, called Degli Insensati, that of the Fools or Simpletons. In various other towns are or were the Academies of the Anxious, of the Confused, of the Impatient, of the Unstable, of the Drowsy, of the Sleepers, of the Awakened, of the Undeceived, of the Agitated, of the Humid, of the Inflamed, of the Insipid, of the Audacious, of the Dead (*Trapassati*), of the Fantastic, of the Nocturnal, of the Dissonant, of the Fluctuating, of the Thundry (*Fulminales*), of the Smoky, of the Ramblers (*Vagabondi*), &c. &c. The Latin name of the Academy della Crusca, we ought to observe, is the *Academia Furfuratorum*, that is, of the bran-sifters. Some interesting information on the early Italian Academies may be found in the 9th chapter of the Life of Galileo, in the *Library of Useful Knowledge*; and in Morhof's *Polyhistor*, and Tiraboschi's *Storia della Letteratura Italiana*, there referred to.

Among the existing Academies of Italy that have not been mentioned above, the following are some of the principal: the Royal Academy of Sciences and Belles Lettres of Naples, founded in 1779: it has published its Transactions, which contain many valuable papers on mathematical subjects, since 1788. The Herculanean Academy of Naples, founded in 1755: the first volume of its Transactions appeared in 1775, under the title of *Antichità di Ercolano*, and it has been followed by several others. The Academy of Etruscan Antiquities at Cortona founded in 1726, and that at Florence founded in 1807, both of which have published valuable Transactions. There are also academies at Padua, Milan, Siena, Verona, and Genoa, by all of which some volumes of Transactions have been printed. The Academy of Bologna was originally founded in 1690, by the afterwards distinguished astronomer Eustachio Manfredi, then only sixteen. The associates called their institution the Academia degli Inquieti, and took for their motto the words *Mens agitat*. In 1714 this academy was united to the University or Institute of Bologna, since which event it has been called the Academy of the Institute, or the Clementine Academy (from Clement XI., the then Pope.) Its Transactions have been published under the title of *Commentarii*, since 1731. To this list we may add the Royal Academy of Turin, in Piedmont, which was originally a private association founded about the middle of the last century, by the young Lagrange, then, although not yet twenty years of age, holding the office of Professor of Mathematics in the Royal Artillery School of that city. The first volume of its Transactions was published, in Latin, in 1759, and surprised the scientific world by some papers of great originality, to which the name of Lagrange was appended. The Turin Transactions, which continued for some years to be enriched by the contributions of this eminent mathematician, were published, in Latin, till 1784, since which time they have appeared in French.

II. French Academies.—We shall not here notice the ancient society established, it is said, about the middle of the twelfth century, at Toulouse, for the cultivation of poetry, or, as it was then called, the Gay Science, although it has been sometimes designated an academy. An account of that, and of other institutions of a similar description, will be more fitly given under the head Troubadours. The earliest of the French Academies, properly so called, is of much more recent date. The Académie Française was instituted in 1635 by Cardinal Richelieu, for an object of the same nature with that proposed by the Academy della Crusca,—the purification, regulation, and general improvement of the national tongue. This society, in imitation of its Italian model, published in 1694 the first edition of a French Dictionary, known by the name of the Dictionary of the Academy, to which it afterwards made many additions in successive reprints. This work, however, has scarcely perhaps attained the same authority with that of the Della Cruscan academicians; partly owing, no doubt, to the comparative immaturity of the French language when it was thus attempted to restrain its further growth. The original number of the members of the Académie Française was forty, from whom were elected a director and a chancellor every three months, as well as a secretary, who held his office for life. It used to meet three times a week in a hall appropriated to its use in the Louvre. This constitution it continued to retain till the year 1793, when it was abolished, with most of the other establishments which had subsisted under the ancient government. Two years after it was restored as part of the Institute, of which we shall presently give an account. The next of the French academies, in point of antiquity, is the *Académie Royale des Inscriptions et Belles Lettres.* It was established in 1663, in the reign of Louis XIV., by Colbert, and consisted originally of a few members selected from the Académie Française, who used to meet weekly in the library of that minister, and to employ themselves in inventing designs for medals to be struck in commemoration of the royal victories, examining the paintings and sculptures proposed for the embellishment of Versailles, and discussing the manner in which the gardens of that palace should be laid out and the apartments decorated. They were called, and not inappropriately, if a reference was intended to their occupations as well as to their numbers, *La Petite* Académie, the little academy. Their place of meeting was afterwards changed to the same room in the Louvre in which the Académie Française assembled, and they then began to hold two sittings in the week. In 1701 this academy was placed, by an edict of the king, upon a new and more extended foundation; and from this date it published every year a volume of memoirs, many of great value, till it was suppressed at the Revolution. It consisted, at the period of its suppression, of ten honorary members, ten pensionaries, and twenty associates, exclusive of several corresponding members. The Académie Royale des Sciences was originally established by Colbert in 1666, but was entirely remodelled in 1699. By the new constitution its researches were confined to the department of the physical sciences. The Académie des Sciences first began to publish its Transactions in 1666, and from 1699 a volume appeared regularly every year till the academy was suppressed in 1793. These three academies, together with the Académie Royale de Peinture et de Sculpture, which had been rather a school of painting than an association of cultivators of the art, were restored by the Directory in 1795, and united into what was called the National Institute. A new organization was given to this establishment by Bonaparte in 1802; and it was finally remodelled in the form in which it still exists soon after the second restoration of the Bourbons in 1816. As now constituted, the Institute, or Académie Royale, consists of five divisions; the first called the Académie des Sciences, composed of sixty-five ordinary and one hundred corresponding members; the second called the Académie Française, composed of forty members; the third called the Académie des Inscriptions et Belles Lettres, composed of forty ordinary and sixty corresponding members, together with eight associates; the fourth, called the Académie des Beaux Arts, composed of forty-one ordinary and thirty-six corresponding members, with eight associates; and the fifth, which has been only lately added, called the Académie des Sciences Morales et Politiques, composed of thirty members. Each class meets by itself once a week. Vacancies are filled up by the votes of the members, subject to the approval of the king; and each of the regular members receives a salary of 1500 francs per annum. The meetings of all the classes are held in the hall which was formerly the Chapel of the College of the Four Nations, now called the Palais des Beaux Arts. The French Institute has, since its establishment, ranked as the very first of the scientific associations of Europe, the most illustrious of whose philosophers have usually been comprehended in the list of its members.

There is also in Paris the Académie Celtique, founded in 1807, and now called the Société des Antiquaires de France, which has published several volumes of interesting and important *Mémoires.* There are likewise academies in many of the provincial capitals of France; among which the chief are those of Soissons (1675), of Nismes (1682), of Angers (1685), of Lyons (1700), of Bordeaux (1703), of Caen (1705), of Montpellier (1706), of Béziers (1723), of Marseilles (1726), of Rochelle (1732), of Dijon (1736), of Toulouse (1740), of Rouen (1744), of Montauban (1744), of Amiens (1750), of Besançon (1752), of Châlons sur Marne (1753). Many of these institutions have attained considerable celebrity, and some of them have published their Transactions.

III. Spanish Academies.—A society for the cultivation of physical science, under the title of Academia Naturæ Curiosorum, was established at Madrid, in 1652, on the model of the old Academia Secretorum Naturæ, already mentioned as having been founded at Naples in the middle of the preceding century. Of the existing Spanish academies the most important are the following:—The Royal Academy of Spain, founded at Madrid, in 1714, principally by the exertions of the Duke of Escalona. It is constituted on the model of the Academia della Crusca and the Académie Française, and has for its object the improvement and purification of the Spanish language, of which it has published a Dictionary, under the title of *Diccionario de la Lengua Castellana,* six vols. fol., 1726-1739. The Royal Academy of Spanish History: this commenced as a private association at Madrid in 1730, but was taken under the royal protection, and incorporated by Philip V. in 1738. It consists of twenty-four members. The first volume of its Transactions was published in 1796, under the title of Memorias de la Real Academia de la Historia. It has also printed some ancient manuscripts, and given new editions of some historical works; and it has long been engaged in preparing a Geographical Dictionary of Spain. There are also an Academy of History and Geography at Valladolid, and a Literary Academy at Seville, both founded in 1753.

IV. Portuguese Academies.—An Academy of Portuguese History was established at Lisbon, in 1720, by King John V., consisting of a director, four censors, a secretary, and fifty members. But the principal Portuguese academy is the Academy of Science, Agriculture, Arts, Commerce, and general Economy, founded by Queen Maria in 1779. This institution consists of twenty-four *socios veteranos,* or acting members, and thirty-six honorary and foreign associates. It is liberally endowed by the government, and possesses a library, a museum, an observatory, and a printing-press. The members are divided into three classes—1. that of natural science; 2. that of mathematics; and 3. that of Portuguese literature. It has published several volumes of Transactions in different sets; that entitled De Agricultura, commencing in 1787; de Economica, in 1789; de Letteratura Portuguesa, in 1792; and das Sciencias, in 1797. There is also a Geographical Academy at Lisbon, established in 1799, which has published a map of Portugal.

V. Austrian Academies.—Of these the most ancient is the Academia Naturæ Curiosorum, established at Vienna in 1652. In 1687, during the reign of the Emperor Leopold I., it assumed the name of the Academia Cæsareo-Leopoldina. Its Transactions were at first published in separate treatises, but since 1684 they have appeared in volumes, under the title of Ephemerides et Acta Academiæ Cæsareæ Naturæ Curiosorum. A history of this academy was published by Büchner, at Halle, in 1756. The Academy of Arts and Sciences of Vienna was founded in 1705. In 1754 was established in the same city an Academy for the cultivation of the Oriental Languages; and in 1783 a Surgical Academy, which distributes every year three prize medals of the value of fifty guilders each.

VI. Prussian Academies.—The Royal Academy of Science and Belles Lettres of Berlin has long been one of the most eminent among the learned societies of Europe. It was established in 1700, by Frederick I., who appointed the celebrated Leibnitz its first president. The first volume of its Transactions appeared in 1710, under the title of *Miscellanea Berolinensia*, and other volumes followed at intervals of three or four years, till the accession of Frederick the Great in 1740, who, in 1744, took it under his special protection, and proceeded to give it a new organization, with the view of extending its usefulness, and raising it to a higher rank than it had hitherto enjoyed. Maupertuis was appointed its president, and the academy was divided into four classes:—1. The physical class, for natural science; 2. the mathematical class, including astronomy; 3. the philosophical class; 4. the historical and philological class. Each class chooses its own director, who continues in office for life. Vacancies are also filled up by the votes of the members, subject to the approval of the king. Since 1746, a volume of the Transactions has appeared regularly every year. They used to be in French; but are now published in German. The old Memoirs extend to the year 1771; after which date they are called the *Nouveaux Mémoires*, down to 1787; with which year a third series commenced. A history of this academy was published in 1752. In 1798, the Royal Library and Cabinet of Arts were united with, and placed under the superintendence of, the academy; they are now separated. In 1754, was established by the Elector of Mentz, the Electoral Academy at Erfurt, for the promotion of the useful sciences. Its Transactions were originally published in Latin, under the title of *Acta Academiæ Electoralis Moguntinæ Scientiarum Utilium*; but they have of late appeared in German.

VII. OTHER GERMAN ACADEMIES.—Of these, the principal are—the Academy of Sciences, otherwise called the Royal Society, of Göttingen, established in 1733; the Electoral Academy of Science and Bavarian History at Munich, first established in 1760, but greatly enlarged since the erection of Bavaria into a kingdom, and which has published its Transactions, since 1763, in German, under the title of *Abhandlungen der Baierischen Akademie*; that of Mannheim, founded in 1755, by the Elector Charles Theodore, and now divided into three classes—historical, physical, and meteorological: the Transactions of the two former of which have been published, under the title of *Acta Academiæ Theodoro-Palatinæ*—those of the last, under that of *Ephemerides Societatis Meteorologicæ Palatinæ*; and the Academy of Suabian History, established at Tübingen, in Wirtemberg.

VIII. SWEDISH AND DANISH ACADEMIES.—The Royal Academy of Sciences, of Stockholm, was originally a private association, founded by Linnæus, and a few of his friends, in 1739, and was not incorporated by the Crown till two years afterwards. Its Transactions appear in quarterly parts, which form an octavo volume a year. The first forty volumes, from 1739 to 1779, are called the *Old Transactions*; those which have appeared since, the *New*. They are written in Swedish, but have also been translated into German. This academy maintains a professor of experimental philosophy, who, with the two secretaries, is paid from the property which the society has acquired by legacies and donations. From the same source, it distributes every year several gold medals and prizes in money. Stockholm also possesses an Academy of the Belles Lettres, founded in 1753; and an institution denominated the Literary Academy of Sweden, founded in 1786. The object of the latter is the cultivation and improvement of the national language. There is an Academy for the investigation of Northern Antiquities, at Upsal, which has published some valuable volumes of Memoirs. The Royal Academy of Sciences of Copenhagen was founded by the Count of Holstein in 1742, and incorporated the following year. Its Transactions appear in Danish; but they have been partly translated into Latin.

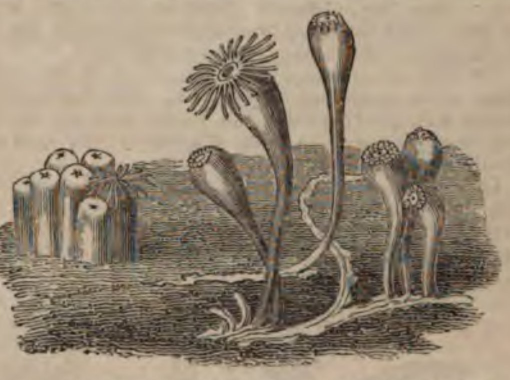
IX. ACADEMIES IN RUSSIA AND POLAND.—The Imperial Academy of Petersburg, like most of the valuable institutions of Russia, originated in the bold and contriving mind of Peter the Great. That monarch, however, did not live to carry into effect the scheme which he had arranged, and which is said to have been suggested to him by his inspection of the academies of France, when in that country in 1717, and to have been matured by consultations with Christian Wolff and Leibnitz. But immediately after his death, in 1725, his successor, Catherine I., proceeded to execute the intentions of her deceased husband; and the Academy was forthwith established, and held its first sitting in December of that year. Some of the most distinguished foreign mathematicians and philosophers of the day were wisely selected by the Empress to grace the new foundation, and induced by liberal salaries to accept places in it under the title of professors. Among them were Wolff, Nicholas and Daniel Bernouilli, Bulfinger, &c. Of these professors there are fifteen in all, besides a president and a director. There are also four adjuncts, from whom vacancies among the professors are always supplied, and who, till thus provided for, are permitted to attend the meetings of the Academy. In its earlier days this institution underwent various fluctuations in reputation and efficiency, according as it happened to be patronized or neglected by the reigning sovereign; but since the accession, in 1741, of the Empress Elizabeth, who placed it upon a broader and more independent basis, it has generally maintained a high character. Its annual revenue is considerable; and one important service, which it has thus been enabled to render, has been the exploration of various portions of the Russian empire, by means of the travellers Pallas, Stolberg, Klaproth, and others, whom it has sent out for that purpose. Its Transactions, down to the year 1747, inclusive, forming fourteen volumes, are in Latin, and are entitled *Commentarii Academiæ Scientiæ Imperialis Petropolitanæ*. Twenty volumes more, down to 1777, likewise in Latin, are entitled *Novi Commentarii*. Since 1777, they take the name of *Acta*, and are partly in Latin and partly in French. Of the whole number of mathematical papers which appeared in these Transactions down to the year 1783, in which he died, the celebrated Euler is computed to have written fully one half; and he left behind him about a hundred additional memoirs, which have appeared in the volumes printed since that period. These papers of Euler's contributed, more than any other publications of the time, to the simplification and improvement of the modern analysis, The Imperial Academy possesses a library of some extent, which contains a considerable number of oriental manuscripts, as well as valuable collections of medals and of specimens of natural history. In 1783, an institution, on the model of the Académie Française, having for its object the improvement of the Russian language, was founded at Petersburg; and was soon after united with the Imperial Academy. A Royal Academy was established at Warsaw in 1753.

Among the other European academies, may be mentioned the Medical Academy of Geneva, founded in 1715; the Académie des Sciences et des Belles Lettres of Brussels, which has published its Transactions, under the title of *Mémoires*, since the year 1777; and the institution of the same name at Flushing, whose Transactions have also appeared. In the British dominions there are no associations for the cultivation of science or learning, which have this name, except the Royal Irish Academy, founded in 1782, and which has published its Transactions since 1787. In North America, as in England, such institutions are, for the most part, called *Societies*, and will be noticed under that term. The following are the only academies which we find enumerated in the *Encyclopædia Americana*, published in 1829:—the American Academy of Arts and Sciences, established at Boston in 1780, which had in 1829 published four volumes of Transactions; the Connecticut Academy of Arts and Sciences, founded at Newhaven in 1799, which had then published one volume; and the Academy of Natural Science, founded at Philadelphia in 1818, of whose Memoirs five volumes had appeared.

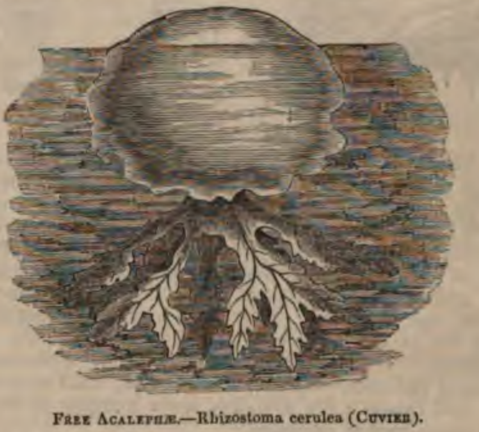
ACADEMY is also the name usually given, both in this country and on the Continent, to an institution established for the cultivation and promotion of the fine arts, that is, of painting, sculpture, architecture, and music. Such institutions commonly partake both of the character of academies, in the sense already explained, and of schools or colleges, consisting, on the one hand, of an association of amateurs and distinguished proficients, professing to have in view the diffusion of a taste for the arts among the public generally, by publications, exhibitions, or any other means which may be made available for that end; and, on the other, of an establishment of teachers or professors, for the instruction of youth in the practice of some one or more of the branches in question. The latter object is effected by lectures, by prescribed tasks, and by the distribution of prizes and honours. Societies of painters, for the promotion and protection of their art, are of very ancient date. So early as the year 1345, the painters of Venice are recorded to have formed themselves into an association of this description. A few years afterwards, —namely, in 1350—those of Florence did the same. In 1391 the artists of Paris followed the example of their Ita lian brethren, and founded what they called the Academy of St. Luke. This establishment was formally recognized by Charles VII. in 1430; and the privileges which he conferred upon it were confirmed by Henry III. in 1584. In 1613 the Academy of St. Luke formed a union with the Society of Sculptors; and the institution subsisted till the Revolution. Towards the middle of the seventeenth century, however, it had been thrown into the shade by a new association, founded by Lebrun, Corneille, and several others of the painters licensed by the king. A royal edict, in favour of this association, was issued in the beginning of the year 1648; and in 1655 letters-patent were granted to it by Cardinal Mazarin. Some time after, it was allowed a hall in the Louvre; and, finally, in 1663, during the administration of Colbert, there was settled upon it a revenue of 4000 livres annually. In 1671, an Academy of Architecture was established by the same minister. These two establishments were abolished with the other academies at the Revolution; but they have since been revived, and now form together the fourth division of the Institute, under the name of the *Académie des Beaux Arts*. It consists of forty-one members, eight associates, and six corresponding members. A branch of this academy still subsists at Rome, which was established in 1666 by Louis XIV., with a revenue of 35,000 livres. There are also Academies of the Fine Arts in many of the chief provincial towns of France. Of the Italian academies of this description, that of San Luca at Rome was established in 1593, by the eminent painter Frederic Zucchero, who erected an elegant building for it at his own expense. There are others at Milan, Bologna, Parma, and many of the other principal towns. The oldest German Academy of the Fine Arts is that of Nuremberg, founded by Joachim Sandrart, an artist of great ability, in 1662. That of Dresden was established in 1697, and was united with those of Leipzick and Meissen in 1764, when it received the form which it still retains. There are others at Berlin, at Vienna, at Munich, at Weimar, and in various other cities. In Spain an Academy of Painting and Sculpture was established at Madrid in 1753. At Amsterdam, Antwerp, and Brussels, there are similar institutions. The Academy of the Fine Arts at Stockholm was established, in 1733, principally by the exertions of the celebrated Charles Gustavus, Count de Tessin; and that of Copenhagen in 1738, though it was not incorporated till 1754. To this institution the famous sculptor Thorwaldsen was indebted for his early education. The *Académie Imperiale des Beaux Arts* of Petersburgh was founded in 1765 by the Empress Catherine II., who endowed it with a considerable revenue. It consists of six professors of painting, sculpture, and architecture, with an adjunct, or assistant, to each, twenty-four honorary members, six councillors, a president, three rectors, and three adjuncts to the rectors. This institution has greatly contributed to the introduction and dissemination of a taste for the arts in Russia, by the pupils whom it has sent out and supported during their studies in foreign countries. A letter, printed by Steele in the 555th No. of the *Spectator* (the last of the original series), speaks of an Academy of Painting, then (1712) lately established in London. Sir Godfrey Kneller is mentioned as its president. This institution, however, probably soon fell into decay. The present Royal Academy originated in an association of painters, who obtained a charter, in 1765, under the title of the Incorporated Society of Artists of Great Britain. This society, however, was soon after broken up by disputes among its members; and in 1768 the Royal Academy of Arts was incorporated in its stead. It consists of forty artists bearing the title of academicians, of eighteen associates, of six associate engravers, and of three or four individuals of distinction, under the name of honorary members. From the academicians are selected the professors of painting, of sculpture, of architecture, and of perspective; and there is also a professor of anatomy, who is commonly a member of the medical profession. Nine of the academicians are likewise appointed annually to officiate in setting the models, and otherwise superintending the progress of the students. The king is the patron of this institution; but its funds are, we believe, entirely derived from the money paid by the public for admission to the exhibition, which takes place every year, in the months of May and June. A branch of the English Royal Academy was established some years ago at Rome. The Edinburgh Royal Academy of Painting was founded in 1754. A similar institution has recently been established in Dublin, under the title of the Royal Hibernian Academy. An Academy of Ancient Music was established in London so early as the year 1710; but a disagreement among its members occasioned its dissolution after it had existed above twenty years. Some time after this the Royal Academy of Music was instituted, with Handel at its head, and for ten years, during which the operas of that great composer were performed under its superintendence in the Haymarket Theatre, enjoyed splendid success. But discord here also came at length to divide and disperse the professors of harmony; and in the year 1729 the institution was broken up. A new Royal Academy of Music, which holds its meetings in a hall in Tenterden-street, was established in 1822. The French Opera, it may be added, is styled the *Académie de Musique.*

ACA'DIA, by the French called ACADIE, is the genuine Indian name of the present province of Nova Scotia. The chief river of Nova Scotia is still called *Shuben-Acadie*, or the *river of Acadie*. [See NOVA SCOTIA.]

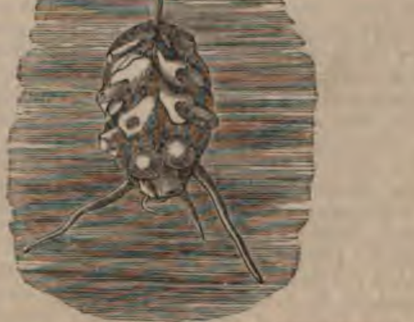
ACALE'PHÆ, a Greek word, signifying nettles. These animals form the third class of Baron Cuvier's zoophytes. Many of them are popularly named *sea-nettles*, from their causing, when touched, a disagreeable sensation similar to the sting of a nettle. Their form is always circular and radiated. There is only one opening into the body, which serves both for the mouth and the vent, and a single cavity which is at once gullet, stomach, and intestines; so that some writers have represented them as being all stomach.



FIXED ACAL.—Alcyonium mammillosum (ELLIS). Actinia sociata (ELLIS).



FREE ACALEPHÆ.—Rhizostoma cerulea (CUVIER).



HYDROSTATIC ACALEPHÆ.—Physophora hydrostatica (FORSKAL).

These animals have been arranged in three orders—1. fixed, 2. free, and 3. hydrostatic.

I. The fixed (*Acalephæ stabiles*) can at pleasure either attach themselves to stones or other objects in the sea, or creep and swim about on the waves. The *Actiniæ* or sea anemones, the *Zoanthæ*, and the *Lucernariæ*, belong to this order.

II. The free (*Acalephæ liberæ*) are not found attached to any object, but always floating about in the water. The *Medusæ* belong to this order.

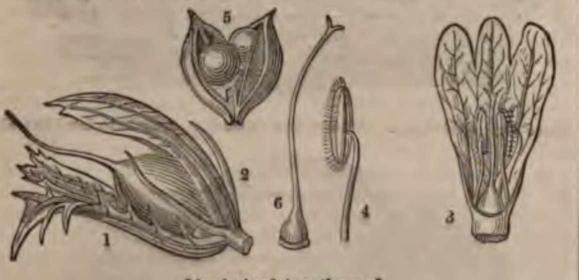
III The hydrostatic (*Acalephæ hydrostaticæ*) are thus named on account of one or more air-vessels, by means of which the animals can raise or sink themselves in the water. Their mouths have not been discovered. The order comprehends the *Physaliæ* and the *Physophoræ*.

In the last edition of the *Règne Animale*, Cuvier makes only two orders—1. The simple (*Acalephæ simplices*); and, 2. The hydrostatic.

M. Eschholtz, of Berlin, has recently published an excellent work on these animals, of which we shall take advantage in describing the several orders.

ACANTHA'CEÆ, a tribe of plants forming one of the natural orders in the Monopetalous division of Dicotyledonous or Exogenous Vegetation. (See DICOTYLEDONES and EXOGENÆ.) Its name is derived from the genus Acanthus, which has been considered characteristic of the whole tribe. The plants of which it is composed are either altogether of an herbaceous nature, or shrubby in a slight degree only; they are extremely common in every tropical country, where they may be considered to occupy the place of the mints, dead-nettles, thymes, and sages of Europe; a few only are found beyond the limits of the tropics. Many of the species are mere weeds; others bear handsome flowers with gaudy colours, but seldom with any odour; a very small number has been occasionally employed medicinally as emollients or diuretics.

The roots of Acanthaceæ are either annual or perennial. The stems are usually four-cornered when young, but afterwards become nearly round; their inside is occupied by a large proportion of pith, which is enclosed in a thin layer of imperfectly formed wood; and at each joint there is a slight tumour with an articulation, by which they are readily known from both Scrophularineæ and Verbenaceæ. Their flowers are often inclosed within large, leafy, imbricated bracteæ (1). The calyx (2) is usually composed of either four or five parts, which overlap each other, and occasionally grow together at the base. The corolla (3) is monopetalous and irregular. The stamens (4) are either two, or four, but in the latter case are of unequal lengths. The pistillum (6) is superior and turoilled. The seed-vessel (5) contains two cells, which burst when ripe, often with elasticity, and expose a few roundish seeds hanging to the cells by curious-hooked processes.



[Analysis of Acanthaceæ.]

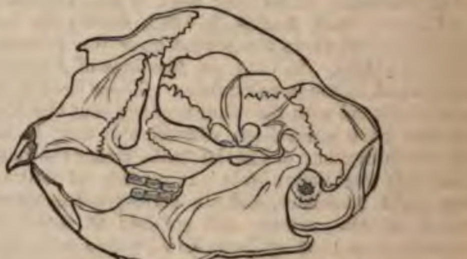
The stems of all the species emit roots very readily from their tumid articulations; on which account gardeners universally increase them by cuttings of the full-grown branches. They are always easy to cultivate, provided they are not kept in too cold or too dry a situation. The annual kinds freely produce seeds, by which they are readily multiplied.

The most common genera are Justicia, Acanthus, Ruellia, Thunbergia, Barleria, and Eranthemum, which see.

For further information, see *Brown's Prodromus Floræ Novæ Hollandiæ*—*Bartling's Ordines Naturales*—*Lindley's Introduction to the Natural System*—and, above all, *Nees v. Esenbeck's Exposition*, in the third volume of *Dr. Wallich's Plantæ Asiaticæ rariores*.

ACA'NTHION, in Zoology, a genus of Rodentia, established by M. F. Cuvier, and embracing two species, which are only known, at present, by their osteology. In the number and form of their teeth, these animals agree in all respects with the common porcupine, from which, indeed, they only differ in the general form or outline of the cranium, and the comparative developement of the bones of the face and skull; characters which have no very assignable influence upon the habits and economy of animal life, and which will, probably, be merged in others of greater importance, when we come to be better acquainted with the species in question. Indeed we have introduced the present article principally for the purpose of attracting the attention of travellers and residents in our Indian Colonies; many of whom have daily opportunities of elucidating this and other obscure subjects in zoology, and only require to be informed of its wants to render the most essential service to the science.

Fig. 1.



To guide observers who may have an opportunity of pursuing this inquiry, we have engraved (*fig.* 1) the skull of a species of porcupine sent from Java by the French traveller, Duvancelle, and figured by M. F. Cuvier, in the ninth volume of the *Mémoires du Museum*, as the type of his genus *Acanthion*.

Fig. 2.

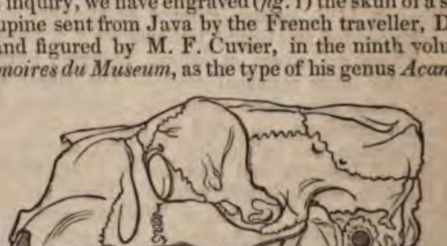


Fig. 2. represents the skull of the common Italian porcupine, for the purpose of comparison. The principal differences which these skulls present, when compared with one another, consist in the surface of the forehead being nearly flat in the acanthion, instead of forming a spherical elevation as in the porcupine; and in the nasal bones being of much smaller dimensions in the former than in the latter animal. The sense of smell would thus appear to be less acute in the Javanese porcupine than in that of Europe and Africa; but it has the region of the brain comparatively larger. M. Cuvier reckons two species:—

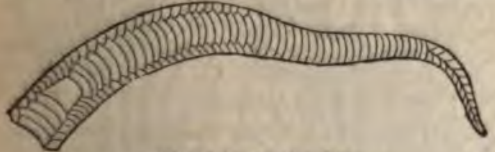
1. *The Acanthion Javanicum*, founded upon the skull already mentioned, as having been sent from Java by M. Duvancelle. This is, probably, the *Babi-landak*, mentioned in Marsden's *History of Sumatra*, and which that author identifies with the *Hystrix Macroura* of Linnæus, a species equally obscure. This animal is represented as having five toes on each foot, the body covered with weak spines, and a long tail, terminating in a thick tuft, of which the spines are knotted, and spring out of one another like grains of rice.

2. *The Acanthion Daubentonii*, founded upon a skeleton formerly described by Daubenton, but which he mistook for that of the common porcupine. The locality from which this skeleton was obtained is not exactly known; but there is reason to believe that it was brought from some part of Africa. It may, perhaps, belong to the fasciculated porcupine, which has been lately found to inhabit the Island of Fernando Po; and which, to judge from the external appearance of the living specimen formerly possessed by the Zoological Society, appears to have all the characteristic marks which M. F. Cuvier assigns to the genus Acanthion.

It may be observed, in conclusion, that, besides the common porcupine (which inhabits every part of the Indian Continent, as well as Africa and the South of Europe), the large islands of Borneo, Sumatra, and Java, the Malayan Peninsula, and probably other parts of Eastern Asia, contain three or four different but closely allied species, of which we have, at present, but a very vague and confused account.

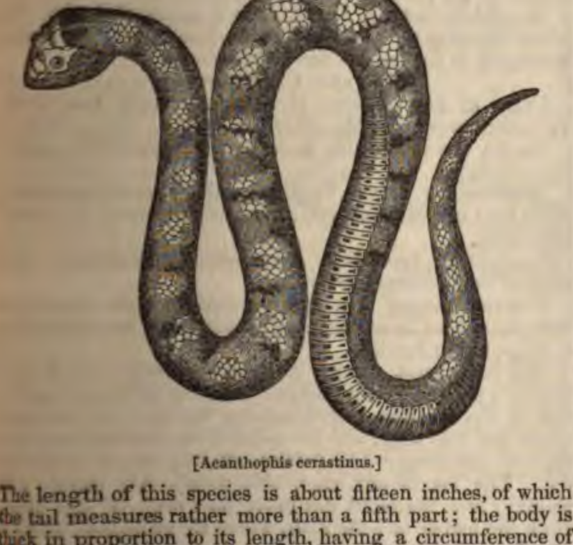
ACA'NTHOPHIS, in Zoology, a genus of venomous serpents, allied to the vipers, but distinguished by having a single series of plates beneath the tail, excepting towards the very extremity, where they are, in some cases, separated into two small rows. The bodies and tails of these animals are elongated and cylindrical; their heads round, obtuse, rather prominent over the eyes, and covered in front with nine or ten polygonal plates. The back and upper surface of the tail are covered with reticulated scales of a rhomboidal form: the breast and belly are covered with single transverse plates; as is likewise the tail, excepting towards the very extremity, which is sometimes furnished with a double row of plates, as in the common viper. The tail is terminated by a little spur, or horny excrescence, which has suggested the name of Acanthophis (that is, *thorn* or *spur* snake), for this genus. This is, however, but a very secondary characteristic, and of little use in distinguishing these animals; since it exists equally in many other species of very different genera, such as the collared, and the black and white snakes, and even in the common viper. It springs out of the very end of the tail, and does not appear to be of the same utility as the two horny spurs which grow upon each side of the anus in the pythons and boas, and which being retractile, or capable of being erected and depressed at will, execute important functions in the economy of these animals.



[Tail of the Acanthophis.]

The head of the acanthophis is broad and compressed, the mouth capable of great distension, and furnished on each side, besides the retractile poison-fangs common to all the family of truly venomous serpents, with a double row of sharp, curved teeth. The species of this genus are of small size, reside on the surface of the dry land, and feed upon frogs, lizards, and small mammals. They are viviparous, and secrete themselve in rat holes, or beneath the roots of trees; never strangle or crush their prey by coiling themselves round its body, but expect a more speedy and certain victory from the deadly effects of their poison. The most anciently known species is,—

The Acanthophis Cerastinus, first described by Merrem, and so named from the general similarity which it bears, at first sight, to the cerastes, or horned viper, in its short body, large flat head, and eyes surmounted by prominent scales.



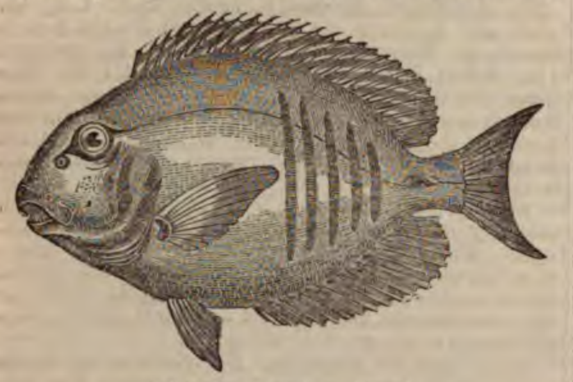
[Acanthophis cerastinus.]

The length of this species is about fifteen inches, of which the tail measures rather more than a fifth part; the body is thick in proportion to its length, having a circumference of two inches and a half in the middle, from whence it gradually tapers towards either extremity. The colour is a pearly-grey above, with obscure transverse dusky or bluish undulations beneath, pale yellow brown, with a small transverse oval black spot on the edge of every abdominal plate; and, in the middle, a similar range of spots from the vent to the end of the tail. The tail itself is cylindrical on the upper surface, and flat beneath, and the spur which terminates it is extremely sharp-pointed, compressed, and slightly bent upwards. The native country of this species is unknown; at least Merrem, who first described it, was ignorant of the country from which his specimen was obtained, and it does not appear to be indicated by any traveller.

The Acanthophis Brownii is briefly described by Dr. Leach, and figured in the first volume of the *Naturalist's Miscellany*. The specific name is given out of compliment to Mr. Robert Brown, the celebrated botanist, from whose manuscripts the brief description of Dr. Leach was taken. The body is said to be of a uniform dark brown, the under lip whitish, the upper with a transverse groove in front, the tail small and rather abruptly contracted at its junction with the body, and the apex compressed laterally. Such, with the additional fact that it is an inhabitant of New Holland, is the very meagre account of this serpent, supplied by Dr. Leach. Mr. Peter Cunningham, however, in his entertaining publication on the present state of New South Wales, informs us, that it is the most venomous serpent of that colony; and suspects that this and a kindred species, of a light orange colour, are male and female, as they have been found to inhabit the same hole. He relates a remarkable fact proving the tenacity of life of these animals. Two individuals, a male and female, were discovered by the dogs of a sportsman: the black one was killed, and the head completely severed from the body, but the female escaped into the hole; upwards of ten minutes afterwards one of the dogs, in hunting about where the snake had been killed, was bitten in the foot by the head which had been cut off, and shortly after died in the most dreadful convulsions.

ACANTHOPTERY'GII, in Zoology, one of the three primary grand divisions, or natural orders, of fishes, which Cuvier has finally established, or rather restored, in his *Histoire Naturelle des Poissons.* (Natural History of Fishes.) This great naturalist has divided fishes into three orders, — *Chondropterygii* (from χόνδρος cartilage, and πτέρυξ a wing or fin), or *Cartilaginous* fishes, without a solid bony skeleton; *Acanthopterygii*, fishes having bony skeletons with prickly spinous processes in the dorsal fins (hence their name); and *Malacopterygii*, (μαλακός, soft, &c.) fishes with bony skeletons, indeed, but with soft articulated radii in the dorsal fins. These three grand divisions, founded upon natural and intelligible principles, because characterized by modifications of organic structure, which exercise an obvious and important influence upon the habits and economy of these animals, were first of all recognized by our celebrated countrymen, Willoughby and Ray. These naturalists were the earliest in the attempt to give a systematic form to zoology, and to raise this branch of knowledge to the rank and importance of a *Science*, by applying to its investigation the principles of the inductive philosophy. The system which these great men had left incomplete and imperfect, a thing unavoidable in all first attempts, was further developed by the celebrated Artedi, in whose hands the three orders above-mentioned became co-ordinate divisions, together with the *Branchiostegi*, since suppressed by Baron Cuvier. After undergoing various changes in the hands of intermediate zoologists, and being even discarded altogether by the school of Linnæus, the system of Artedi is again triumphant; having been lately restored by M. Cuvier, who, after many years devoted to the study of this branch of zoology, and after various attempts to form a system of his own, finally acknowledges that it is the only arrangement conformable to the actual phenomena which we observe among these animals. M. Cuvier divides the acanthopterygious fishes into thirteen natural families, which he calls after the names of their typical or most common genera; but which he has failed to distinguish by exclusive and unequivocal characters. The imperfect state in which he has left his *Histoire Naturelle des Poissons* is not the least to be lamented among the weighty losses which the scientific world has sustained by the recent death of this truly great man.

ACANTHU'RUS (a Greek compound signifying Thorn tail), in Zoology, a genus of Acanthopterygious Fishes, established by Bloch and Lacepede, and adopted by subsequent writers. This genus, separated from the Chætodons of Linnæus, contains, at present, a great number of species, many of which are remarkable for the beauty of their external forms, and the variety of their colours. They are distinguished from proximate genera by the form of the body and tail, which are exceedingly compressed;—so much so, that the depth of the body, measured from the dorsal to the pectoral fins, is always equal to, and often exceeds, its length from head to tail;—by their trenchant teeth, denticulated like a very fine comb; but above all, by the moveable spines, edged and sharp like a lancet, with which they are armed on each side of the tail, and with which they inflict dangerous wounds upon the hands of those who touch them incautiously. It is this circumstance that has acquired for the Acanthuri the name of 'Doctors,' by which they are well known to the English sailors and colonists. These animals have the mouth small, and the muzzle rather advanced: they are among the small number of fishes which live entirely upon vegetable substances, feeding only upon algæ, fuci, and other marine plants; their intestinal canal is, consequently, longer and more complicated than in other species, and their flesh has a peculiar flavour, very different from that of the piscivorous genera. The dangerous weapons with which Nature has provided these otherwise harmless fishes, are well calculated to defend them from the attacks of the ravenous enemies which every where surround them. As they are not obliged to resort to rapine for procuring food, they are by nature inclined to peace, and never voluntarily commence an attack; but they defend themselves with courage and success against the largest of their assailants. Their lancets, also, are placed in the very situation in which, above all others, they are most efficient and dangerous; not only because the greatest strength of fishes lies in the tail, but likewise because it is in this quarter that their enemies are at once most likely to make the attack, and least prepared to expect resistance. The acanthures abound in all the tropical seas, both of the East and West Indies; they are never known to advance beyond the tropics, and are, consequently, unknown in the more temperate latitudes.



[Chætodon Chirengiens. BLOCH.]

ACA'NTHUS (in Architecture). The name by which the broad raffled leaf used in the enrichment of the Corinthian capital is known. It is thus called because of its general resemblance to the leaves of a species of the acanthus plant; or rather because of a pretty traditional story which the Roman author Vitruvius tells of the fancied origin of the Corinthian capital, in which the leaves are said to be imitated from those of the acanthus. (See CAPITAL, CORINTHIAN.) The same leaf, however, is commonly used in architectural and sculptural enrichments generally; in the enrichment of modillions, of mouldings, and of vases, as well as of foliated capitals; and we gather from Virgil, that the acanthus was by the ancients also employed as an ornament in embroidery. In the first book of the *Æneid*, verse 649, and again at 711, a veil or vest is said to be interwoven or embroidered with the crocus-coloured or saffron acanthus.

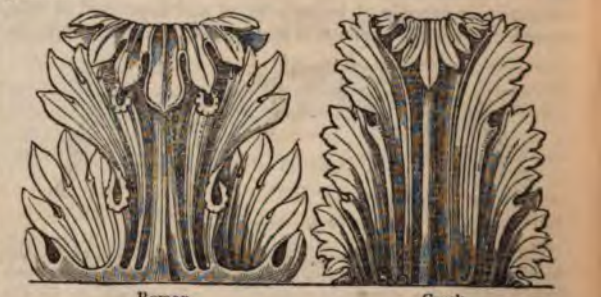
Indeed, it appears to have been a great favourite with that poet himself, both as a plant and as an ornament in works of art. Speaking of the most delightful trees and shrubs for a garden for bees, in the fourth book of the *Georgics*, verses 122 and 123, he says, 'nor could I have passed over in silence the late-blooming narcissus, or the twig of the flexible acanthus;' and in the third eclogue of the *Bucolics*, verse 45, he describes two beautiful beechen cups, on which was carved the scene of Orpheus enchanting the trees, with 'the soft acanthus folded round the handles.'

The application of the brank-ursine acanthus (see next article) to sculptural enrichment is further illustrated in the following passages:—Theocritus, describing a cup of Ætolian manufacture, says, 'the pliant acanthus is expanded *all round the cup*;' and Ovid (*Met.* 13. v. 701.) represents a vase of bronze as being adorned on the outside with a mythological story, and the border above this figured portion as covered with acanthus leaves wrought in gold. Now of these two modes of applying it, as well as of that described by Virgil in his third eclogue, we have very many instances in ancient vases still extant.

Athenæus relates that, in the splendid procession ordained to convey the corpse of Alexander the Great to its final destination in Egypt, the coffin was placed in a car, which was adorned with a small colonnade of golden pillars, and a golden acanthus was set at intervals between the columns.

Pliny the elder, in his *Natural History*, describes the acanthus in such a manner that it can only be recognized in the brank-ursine; and his nephew, in speaking of the successful cultivation of the same plant as an ornament to his garden, leaves no doubt that the brank-ursine is identical with the common architectural and sculptural acanthus.

This ornament, in the ancient Greek and Roman models, is very characteristic of the styles of architectural enrichment of those nations; in the Roman it is full and somewhat luxuriant, and in the Greek more restrained, but simple and graceful.



Roman. Greek.

ACAN'THUS. Under this classical name have been described, by ancient authors, at least three totally different plants. Firstly, a prickly tree with smooth evergreen leaves, and small round saffron-coloured berries, frequently alluded to by Virgil; this is conjectured to have been the *Holly*. Secondly, a prickly Egyptian tree, described by Theophrastus as having pods like those of a bean; it is probable that this was the *Acacia Arabica* (see ACACIA). Thirdly, a herb mentioned by Dioscorides, with broad, prickly leaves, which perish at the approach of winter, and again sprout forth with the return of spring. It is said that the idea of the Corinthian capital of Greek columns was taken from some of the leaves of this acanthus. To this latter plant the name is now applied. The word, in all cases, alludes to the prickly nature of the leaves or stems.

In modern botany, Acanthus is a genus of herbaceous plants found in the south of Europe, Asia Minor, and India, belonging to the natural order *Acanthaceæ*.

GENERIC CHARACTER.

Calyx in four divisions, of which the upper and lower are much larger than the other two.

Corolla one-sided, with three lobes; no trace of an upper lip to be found.

Stamens four, in two lengths; anthers never containing more than one cell, fringed, the upper ones erect, the lower horizontal.

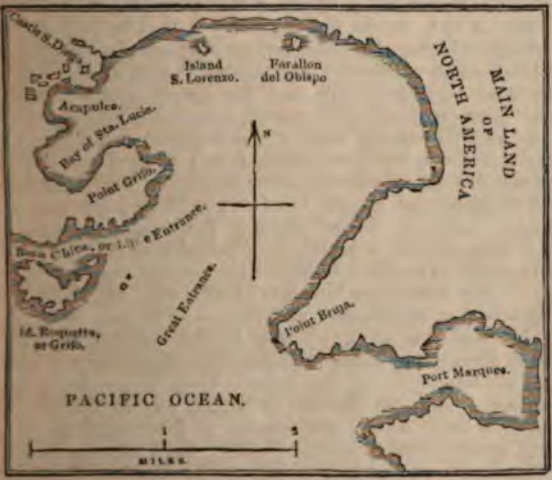
Seed-vessel two-celled, compressed, four-seeded, with sides of the texture of paper.

Flowers growing in a terminal leafless spike, having at their base three floral leaves, of which the intermediate one is fringed with bristles.

The commonest species is *Acanthus mollis*, or *Brank-ursine*, a native of many parts of the South of Europe, growing in shady moist places, among bushes. Its stem is about two feet high, and is covered from the middle to the top with fine large white flowers, slightly tinged with yellow. The leaves are large, soft, deeply cut, hairy, and shining, and surround the lower part only of the stem. Both the leaves and the roots, which are perennial, abound in mucilage, which has caused them to be substituted in domestic medicine for the marsh-mallow. It is this species which is usually supposed to have given rise to the notion of the Grecian capital. But it appears, from the investigation of Dr. Sibthorp, that it is no where to be found, either in the Greek islands, or in any part of the Peloponnesus; and that the plant which Dioscorides must have meant was the *Acanthus spinosus*, still called ἄκανθα, which is found, as he describes it, on the borders of cultivated grounds, or of gardens, and is frequent in rocky moist situations. This species differs from *A. mollis* in having a dwarfer stem, flowers tinged with pink instead of yellow, and spiny leaves, much more deeply cut. Both the one and the other are half-hardy perennials, increased by division of the summit of the root. They have been long cultivated in the gardens of Great Britain, but perish, if not protected, from severe frost.

[Acanthus spinosus.]

ACAPU'LCO, a city in the province of Mexico, about 183 miles S.S.W. of the capital, Mexico; N. lat. 16° 50′, W. lon. 99° 48′. It stands in the recess of a bay, close to a chain of granite mountains, and is the best Mexican port on the coast of the Pacific Ocean. The bay has two entrances formed by the island Roquetta; the comparative dimensions of which may be estimated from the scale attached to the small map. The port is capable of containing 500 ships, and is deep enough to allow vessels to lie close to the rocks.



Acapulco is but poorly built, and is a most disagreeable and unhealthy place. Lying within the torrid zone, and surrounded by mountains, it is intensely hot, and the inhabitants, particularly new comers, are liable to dangerous fevers. Some time back an opening was cut through the rocks on the west to let in the sea-breeze, but a dirty swamp on the east side of the town probably still remains undrained, and is one of the sources of the annual fevers. The city of Mexico, in the interior, communicates with the Pacific by the town of Acapulco, which once had a considerable trade, particularly with Manilla, the capital of Manilla, or Luzon, one of the Philippine islands. Under the Spanish dominion a vessel of the largest size used annually to leave Acapulco for Manilla about February or March, loaded with commodities and specie; and when the English were at war with the Spaniards, the Manilla ships were carefully looked after as a rich booty. The vessel returned to Acapulco in August, carrying back muslins, printed calicoes, coarse cotton shirts, porcelain, Chinese jewellery, &c. Its arrival was the signal for a great concourse of merchants to Acapulco, who swelled the population for the time to about 9000. The monopoly enjoyed by Acapulco while under the dominion of Spain being now abolished, the India and China trade has shifted to the ports of Sam Blas, Mazatlan, and Guaymas; and though its prosperity necessarily suffered by such removal, Mr. Ward, in his *Mexico*, states that its commerce is again reviving. The present number of inhabitants is stated at about 4000, who are principally people of colour. Its exports are cochineal, indigo, silver, and some skins. [See *Dictionnaire Géograph. Universel.*]

ACA'RIDES, a division of ARA'CHNIDES, which comprehends the small spider-like animals popularly termed mites (*Acari*), as well as water-mites and ticks: some of these are wanderers on land or in water; others are fixed upon various animals, whose blood or humours they suck, and even insinuate themselves beneath the skin, and often multiply prodigiously.

These minute animals are not considered by modern naturalists to rank among insects, on account of their structure being very different, and from their having, in most cases, like spiders, eight feet, while no insect has more than six feet. Their mouths, in some, are furnished with jaws (*mandibulæ*), either having pincers or claws, but concealed in a projection of the breast-plate (*sternum*) in form of a lip; in others it is in the form of a syphon or sucker; and in others it presents a simple cavity. M. Latreille makes four divisions of the *Acarides*: 1. Mites (*Trombidites*): 2. Ticks (*Ricinites*): 3. Water Mites (*Hydrachnellæ*): and 4. Flesh Worms (*Microphthira*); the latter distinguished from the other three by having only six feet.

ACARNA'NIA, an ancient division of Northern Greece, which was bounded on the north by the Ambraciot Gulf, now the gulf of Arta, on the north-east by the small territory of Amphilochia, and on the west and south-west by that part of the Mediterranean to which the Greek and Roman writers gave the name of the Ionian Sea. The eastern boundary is not so easy to determine. It extended in the time of Thucydides east of the river Achelous, and encroached upon the territory which seemed the property of the Ætolians. Under the Romans, or somewhat earlier, the Achelous was made the dividing line. Acarnania afterwards became part of the Roman province of Epirus, and Ætolia was attached to the province of Achæa. Acarnania, it is now supposed, will form part of the new kingdom of Greece. It has sometimes been called by the name of Carlelia, or Carnia, in modern times, which appears to be a corruption of the ancient name.

The longest straight line that can be drawn in Acarnania is about fifty miles, from Actium to the mouth of the Achelous. The length of sea-coast from Actium, near the entrance of the Ambraciot Gulf to the mouth of the Achelous, is reckoned, by Strabo, to be about 570 stadia, or 57 miles, reckoning 10 to a mile. Our modern charts give a length of from 70 to 80 miles, measuring in a rough way, along the very irregular outline of the coast. Several good ports are found on this coast, which, added to the general fertility of the country, might have made the people wealthy; but the primitive inhabitants never attained any reputation either in commerce, or the arts, sufficient to transmit their fame to our days. Their best ports were occupied by Corinthian colonies; and the inhabitants, engaged in continual wars with their neighbours, are characterized by Thucydides as living in a state of piracy and robbery, at a time when Athens (which was not 150 miles from the mouth of the Achelous) had seen the dramas of Æschylus and Sophocles, and was adorned with the great works of Phidias.

Thucydides, who wrote during the Peloponnesian war (which commenced B.C. 431), is the earliest extant writer who gives us any exact information about a people called Acarnanians, inhabiting the country which we have called Acarnania. It is difficult to give, in a limited space, any definite or correct idea of the origin of many of the Greek nations. The Acarnanians are never mentioned by Homer, though their neighbours and brethren, the Ætolians, are; and this would tend to prove that the name of Acarnanians as the name of a people, is not so old as the time of Homer. They belonged, probably, at least in part, to an old and widely diffused race called the Leleges; and, by gradual intermixture with Hellenic (Greek) stock, became, to a certain extent, a Greek people. In the course of time they formed a kind of union and civil polity, which Aristotle thought worth describing; but his work is lost.—[See Ætolians.]

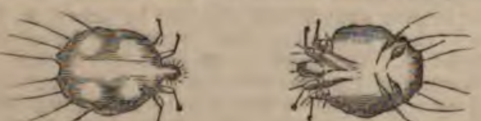
We have hardly attempted any description of the interior of this country, because it is next to impossible to state anything about it that is either very precise or important. In its present wretched condition, it is very thinly inhabited, and very little cultivated. There can be no doubt that it contains a considerable portion of good soil; and we have lately been informed, on trustworthy evidence, that among its mineral treasures are sulphur and coal. There are several lakes in Acarnania.

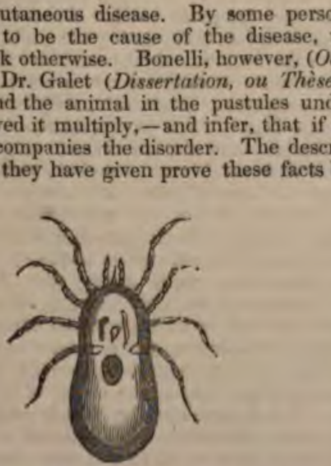
Bordering on Acarnania, on the north-east, was the small territory of Amphilochia, which, with its capital Argos, was sometimes reckoned a part of Acarnania, owing to the political connexion between the two people. It lay on the south-east and eastern coast of the Ambraciot Gulf; and its eastern boundary may have been the Achelous, or rather the mountain chain, which here forms the western margin of the basin of that river. Tradition named Amphilochus, the son of Amphiaraus, as the founder of the state of Amphilochia, and of its capital Argos, after his return from the war of Troy. [See Argos.] Amphilochia, together with Acarnania, became part of the Roman province of Epirus.—[See Actium.]

A'CARUS. The mite, a genus of insects belonging to the Acarides, under which Linnæus comprehended a great number of rather heterogeneous species. M. Latreille (*Règne Animal*, edit. 1829) confines the generic name to the species which have the feelers (*palpi*) forked, very short or concealed, the body very soft, or without a scaly crust. The feet have, at their extremity, a vesicular cushion. Among these species are enumerated the following:—

The domestic mite (*Acarus domesticus*, De Geer), is very commonly found in collections of insects and stuffed birds, and is exceedingly destructive to cabinets. The effluvia of camphor has some effect in destroying this pest, but is not powerful enough to prevent it altogether. Moistening the specimens with a weak solution of corrosive sublimate, is said to prove an effectual preventive.

The itch mite (*Acarus Scabiei*, Fabricius) is a microscopic animal, found under the human skin in the pustules of a well-known cutaneous disease. By some persons the insect is believed to be the cause of the disease, though many authors think otherwise. Bonelli, however, (*Observations*, p. 67) and Dr. Galet (*Dissertation, ou Thèse inaugurale*), have found the animal in the pustules under the skin,—have observed it multiply,—and infer, that if it does not produce, it accompanies the disorder. The descriptions and figures which they have given prove these facts beyond question.

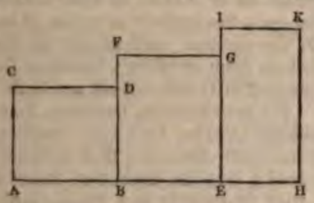


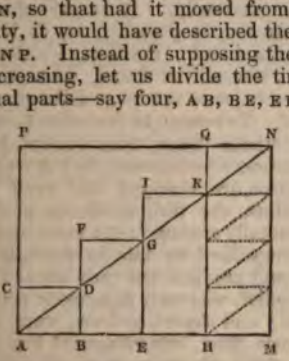


The sparrow mite (*Acarus passerinus*, Fabricius) is distinguished by the remarkable size of its third pair of legs. Geoffroy called it the bat tick, and Latreille formerly placed it in his genus *Sarcoptes*, now abandoned. Baron de Geer has given a good description of it with figures. (Tom. vii. Tab. 6.)

ACCELERATED MOTION, ACCELERATING FORCE, ACCELERATION. When the velocity of a moving body is continually increased, so that the lengths described in successive equal portions of time are greater and greater, the motion is said to be accelerated, which is the same thing as saying that the velocity continually increases. [See Velocity.] We see instances of this in the fall of a stone to the earth, in the motion of a comet or planet as it approaches the sun, and also in the ebb of the tide. As it is certain that matter, if left to itself, would neither accelerate nor retard any motion impressed upon it, we must look for the cause of acceleration in something external to matter. This cause is called the *accelerating force*, see Inertia, Force, Cause, to the remarks in the last of which articles we particularly refer the reader, both now and whenever the word cause is mentioned. At present the only accelerating forces which we will consider, are the action of the earth, and the various weights produced by it.

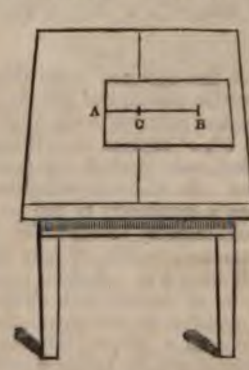
It is observed, that when a body falls to the ground from a height above it, the motion is *uniformly* accelerated; that is, whatever velocity it moves with at the end of the first second, it has half as much again at the end of a second and a half; twice as much at the end of two seconds; and so on. · At least this is so nearly true, that any small departure from it may be attributed entirely to the resistance of the air, which we know from experience must produce some such effect. And this is the same with every body, whatever may be the substance of which it is composed, as is proved by the well-known experiment of the guinea and the feather, which fall to the bottom of an exhausted receiver in the same time. The velocity thus acquired in one second is called the measure of the accelerating force. On the earth it is about 32 feet 2 inches per second. If we could take the same body to the surface of another planet, and if we found that it there acquired 40 feet of velocity in the first second, we should say that the accelerating force of the earth was to that of the planet in the proportion of $32\frac{1}{6}$ to 40. By saying that the velocity is $32\frac{1}{6}$ feet at the end of the first second, we do not mean that the body falls through $32\frac{1}{6}$ feet in that second, but only that if the cause of acceleration were suddenly to cease at the end of one second, the body would continue moving at that rate. In truth, it falls through only half that length, or $16\frac{1}{12}$, in the first second. It may be proved mathematically, that if a body, setting out from a state of rest, has its velocity uniformly accelerated, it will, at the end of any time, have gone only half the length which it would have gone through, had it moved, from the beginning of the time, with the velocity which it has acquired at the end of it. Thus, if a body has been falling from a state of rest during ten seconds, (the resistance of the air having been removed,) it will then have a velocity of $32\frac{1}{6} \times 10$ or $321\frac{2}{3}$ feet per second. Had it moved through the whole ten seconds with this velocity, it would have passed over $321\frac{2}{3} \times 10$ or $3216\frac{2}{3}$ feet. It really has described only the half, or $1608\frac{1}{3}$ feet. We may give an idea of the way in which this proposition is established, as follows:—The area of a rectangle [See Rectangle], that is, the number of *square feet* it contains, is found by multiplying together the numbers of *linear feet* in the sides. Thus, if AB be 4 feet, and AC 5 feet, the number of square feet in the area is 4 × 5, or 20. Again, the number of feet described by a body moving with a uniform velocity, for a certain number of seconds, is found by multiplying the number of seconds by the number of feet per second, or the velocity. If, then, AB contain as many feet as there are seconds, and AC as many feet as the body moves through per second; as many feet as the body describes in its motion, so many square feet will there be in ABDC. That is, if we let AB *represent* the time of motion, and AC the velocity, the area ABDC will *represent* the length described in the time AB, with the velocity AC. Not that ABDC is the length described, or AB the time of describing it; but AB contains a foot for every second of the time, and ABDC contains a square foot for every foot of length described. Similarly, if at the end of the time just considered, the body suddenly receives an accession of velocity DF, making its whole velocity BF per second; and if with this increased velocity it move for a time which contains as many seconds as BE contains feet, the length described in this second portion of time will contain as many feet as BEGF contains square feet: and the whole length described in both portions of time will be represented by the sum of the areas ABDC and BEGF. And similarly for another accession of velocity GI, and an additional time represented by EH. Now, let a body move for the time represented by AM; at the beginning of this time let it be at rest; and by the end, let it have acquired the velocity MN, so that had it moved from the beginning with this velocity, it would have described the length represented by AMNP. Instead of supposing the velocity to be perpetually increasing, let us divide the time AM into a number of equal parts—say four, AB, BE, EH, HM, and let one-fourth of the velocity be communicated at the beginning of each of these times, so that the body sets off from A, with the velocity AC, which continues through the time represented by AB, and causes it to describe the length represented by ABDC. We know from geometry [See TRIANGLES, SIMILAR] that BD, EG, and HK, are respectively one-fourth, one-half, and three-quarters of MN, which is also evident to the eye, and may be further proved by drawing the figure correctly, which we recommend to such of our readers as do not understand geometry. Hence GE or BF is the velocity with which the body starts at the end of the time AB; EI at the end of AE; and HQ at the end of AH. Consequently, the whole length described is a foot for every square foot contained in ABDC, EBFG, EIKH, and HQNM, put together. But this is not a uniformly accelerated velocity, for the body first moves through the time AB, with the velocity AC, and then suddenly receives the accession of velocity DF. But if, instead of dividing AM into four parts, we had divided it into four thousand parts, and supposed the body to receive one four-thousandth part of the velocity MN at the end of each of the parts of time, we should be so much nearer the idea of a uniformly accelerated velocity as this, that instead of moving through one-fourth of its time without acquiring more velocity, the body would only have moved one four-thousandth part of the time unaccelerated. And the figure is the same with the exception of there being more rectangles on AM, and of less width. Still nearer should we be to the idea of a perfectly uniform acceleration if we divided AM into four million of parts, and so on. Here we observe, 1. that the triangle ANM is the half of APNM; 2. that the sum of the little rectangles ACDB, BFGE, is always greater than the triangle ANM, by the sum of the little triangles ACD, DFG, &c.; 3. that the sum of the last-named little triangles is only the half of the last rectangle HQNM, as is evident from the inspection of the dotted part of the figure. But by dividing AM into a sufficient number of parts, we can make the last rectangle HQNM as small as we please, consequently we can make the sum of the little triangles as small as we please, that is, we can make the sum of the rectangles ACDB, &c., as near as we please to the triangle ANM. But the more parts we divide AM into, the more nearly is the motion of the body uniformly accelerated; that is, the more nearly the motion is uniformly accelerated, the more nearly is ANM the representation of the space described. Hence we must infer (and there are in mathematics accurate methods of demonstrating it), that if the acceleration were *really* uniform, ANM would really have a square foot for every foot of length described by the body. That is, since ANM is half of APNM, and the latter contains a square foot for every foot of length which *would have been* described if MN *had been* the velocity from the beginning, we must infer that the length described by a uniformly accelerated motion from a state of rest, is half that which would have been described, if the body had had its last velocity from the beginning.





If the body begins with some velocity, instead of being at rest, the space which it would have described from that velocity must be added to that which, by the last rule, it describes by the acceleration. Suppose that it sets out with a velocity of 10 feet per second, and moves for 3 seconds uniformly accelerated in such a manner as to gain 6 feet of velocity per second. Hence it will gain 18 feet of velocity, which, had it had at the beginning, would have moved it through 18 × 3 or 54 feet of length, and the half of this is 27 feet. This is what it would have described had it had no velocity at the beginning; but it has 10 feet of velocity per second, which, in 3 seconds, would move it through 30 feet. Hence 30 feet and 27 feet, or 57 feet, is the length really moved through in the 3 seconds.

Similarly we can calculate the effects of a uniform *retardation* of velocity. This we can imagine to take place in the following way. While the body moves uniformly from left to right of the paper, let the paper itself move with a uniformly accelerated velocity from right to left of the table. Let the body at the beginning of the motion be at the left edge of the paper, and let that edge of the paper be placed on the middle line of the table. Let the body begin to move on the paper uniformly 10 inches per second, and let the paper, which at the beginning is at rest, be uniformly accelerated towards the left, so as to acquire 2 inches of velocity in every second. At the end of 3 seconds, the body will be at B, 30 inches from A, but the paper itself will then have acquired the velocity of 6 inches per second, and will have moved through the half of 18 inches or 9 inches; that is, AC will be 9 inches. Hence the distance of the body from the middle line will be CB, or 21 inches. Relatively to the paper, the velocity of the body is uniform, but relatively to the table, it has a uniformly retarded velocity. At the end of the fourth second, it will have advanced 40 inches on the paper, and the paper itself will have receded 16 inches, giving 24 inches for CB. At the end of the fifth second, AB will be 50 inches, AC 25 inches, and CB 25 inches. At the end of the sixth second, AB will be 60 inches, AC 36 inches, and BC 24 inches, so that the body, with respect to the table, stops in the sixth second, and then begins to move back again. We can easily find when this takes place, for, since the velocity on the paper is 10 inches per second, and that of the paper gains 2 inches in every second, at the end of the fifth second the body will cease to move forward on the table. At the end of 10 seconds it will have returned to the middle line again, and afterwards will begin to move away from the middle line towards the left. At the end of the twelfth second, it will have advanced 120 inches on the paper, and the paper will have receded 144 inches, so that the body will be 24 inches on the left of the middle line.



The general algebraical formulæ which represent these results are as follow. Let a be the velocity with which the body begins to move, t the number of seconds elapsed from the beginning of the motion, g the velocity acquired or lost during each second. Then the space described in a uniformly accelerated motion from rest is $\frac{1}{2}gt^2$; when the initial velocity is a, the space described in an accelerated motion is $at+\frac{1}{2}gt^2$, and in a retarded motion the body will have moved through

$at-\frac{1}{2}gt^2$ in the direction of its initial velocity if at be greater than $\frac{1}{2}gt^2$, or will have come back and passed its first position on the other side by $\frac{1}{2}gt^2-at$, if at be less than $\frac{1}{2}gt^2$. In the last case it continues to move in the direction of its initial velocity for $\frac{a}{g}$ seconds and proceeds in that direction through the space $\frac{1}{2}\frac{a^2}{g}$.

For further explanation as to velocities which are accelerated or retarded, but not uniformly, see VELOCITY.

ACCELERATION *of the Moon's Mean Motion.* } See PLANETARY PERTURBATIONS.
ACCELERATION *of the Motion of Comets.* }

ACCENT (in Mathematics). To avoid the confusion arising from the use of many letters in an algebraical problem, and on other accounts, it is customary to signify different magnitudes of the same kind, or magnitudes similarly connected with the question, by the same letter, distinguishing these magnitudes from one another by accents. It is, therefore, to be understood, that the same letter with two different accents, may stand for magnitudes as different in value as those represented by different letters. The convenience of the accent may be illustrated as follows. If a men can do b things in c days, and e men can do f things in g days, we have the following equation:—

$$afc = ebg.$$

Now, instead of using e, f, and g, in the second part of the question, let us use the letters which stood for the corresponding quantities in the first part, with accents; that is, let a' men do b' things in c' days. The equation then becomes

$$ab'c = a'bc'.$$

In this new form of the equation some things are evident to the eye, to ascertain which, had the first equation been used, we must have had recourse to the question itself. For instance, that if a'', b'', c'' express men, things, and days, as above, $ab''c = a''bc''$, only placing two accents now where there was one before. In many investigations the judicious use of accents gives a symmetry to the processes and expressions which could scarcely be otherwise obtained.

For the unmathematical reader, we may illustrate the use of accents in the following way. Let us suppose a bookcase to consist of four rows of shelves, each divided into six compartments. If we call the six compartments in the lowest range, A, B, C, D, E, and F, respectively, we might let the compartment directly over A be called G, and so on; but it would be much simpler and easy of recollection to call this compartment A′, the one over *it* in the third row A″, and so on. Thus each letter would indicate a certain vertical line of compartments, while the accent would point out in which horizontal line the one designated is to be found. This is precisely the mathematical use of the accent. All quantities of the same kind, or which the problem places in similar positions, are designated, with regard to this question, by the same letter.

The accented letter a' is read *a accented*, or *a dashed*; a'' is read *a twice accented*, or *a twice dashed*, or more conveniently, though without much attention to idiom, *a two dash*, &c.; where accents become too many to be used with convenience, the *Roman* figures are substituted for them. Thus a^{iv} would be used for a''''. The Roman figures prevent this being taken for a^4, or a multiplied three times by itself. The young algebraist should be cautious how he uses accents, until experience has taught him to do so with propriety. The accented letter is the *metaphor* of algebra; and expressions of the greatest symmetry may be deprived of all their beauty, and even much of their meaning, by a wrong use, or even a want of this notation.

ACCENT. When a child begins to read, he is apt to pronounce all the syllables of a word in the same key, with the same loudness and clearness, dwelling the same time upon each, and pausing the same time between each pair. He soon, however, learns that, in nearly every word, there is one syllable at least which must be distinguished from the rest by a more impressive utterance, as in the examples *respéct, respéctful, respéctable.* If the word is a long one, it requires a second accent, as *respéctability, mánufáctory, immórtalíze.* On the other hand, when short words come together, one or two are often devoid of accent, as in the phrase *ón the tóp of a hill.* When it is stated that the accented syllable is pronounced more impressively than the rest, it is not meant that all accented syllables are to be equally impressive. In the examples given above, the first accent in *mánufáctory* seems to be weaker than that on the third syllable; so the last accent in *immórtalíze*, and that attached to the preposition *on*, among the six monosyllables, *ón the tóp of a hill*, are comparatively very faint. The consideration of accent often determines whether or not we pronounce the initial *h* [See A or AN]; and, consequently, whether the article *an* or *a* is to be used before such a word. Upon accent depends the melody of verse, at least in modern languages. Of the ancient, particularly the Greek accent, it is better to abstain from speaking, because the opinions of people on the subject of Greek accent are both unsettled and contradictory. We may remark, however, that it is the practice of the modern Greeks, in a very great number of instances, to put the chief stress on that syllable which, in our printed Greek books, has the accentual mark (′) on it; but, in doing this, they frequently and unavoidably neglect the stress on those syllables which we are accustomed to pronounce most emphatically. It is said that the principle of Greek versification is *quantity*, or, as it is defined, the mere duration of a sound. Possibly, on a closer examination of the question, it would be found, that what the ancients meant by *quantity*, was not very different from what we mean by *accent*. To return to the safer ground of our own language, the reader of our older writers, Shakspeare and Milton, for instance, should know that the accents of words from time to time are changed, and even variable at the same time. Thus, the verb which we call *tríumph*, was with Milton generally *triúmph*; the noun and the verb being commonly distinguished by him in the same way as *próduce* the noun and *prodúce* the verb are at the present day. What we call *spírit*, was with him more commonly *spiríte*, or almost *spríte*; and *áspect, prócess*, were *aspéct, procéss.* Even in our own time, *advertísement* has become *advértisement*. In these changes, the usual tendency in our language is, and has been, to throw the accent farther back from the end of the word. Such a tendency is, perhaps, inherent in all languages, and seems to arise solely from an endeavour to save labour by rapidity of utterance.

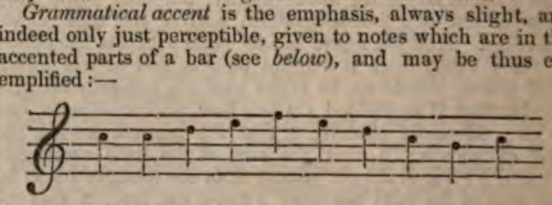
The symbols employed to denote accents are three, the acute (´), the grave (`), and the circumflex (ˆ). We have hitherto spoken only of the first. The second in the ancient languages is said to denote the opposite to the acute, or, perhaps, the absence of it; while the circumflex, we are told, marks a compound of the two, first a rising and then a falling of the voice in the articulation of the same syllable.

These three little marks, as employed in the orthography of the French language, have a signification altogether different. As the French, like all other languages, is deficient in the number of characters used to mark the vowel sounds, it has been found convenient to employ the three symbols given above. Thus, the sounds of *e, é, è, ê*, in the mouth of a Frenchmen, differ not so much in point of *accent* as in the real articulation.

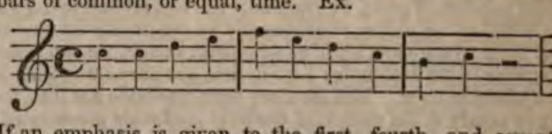
Emphasis differs from *accent*, and is properly used with reference to some one word, or part of a sentence, to which a speaker wishes to draw attention by giving it a more marked pronunciation. (See EMPHASIS.)

ACCENT, in Music, signifies, in a general sense, emphasis, and is either grammatical or oratorical.

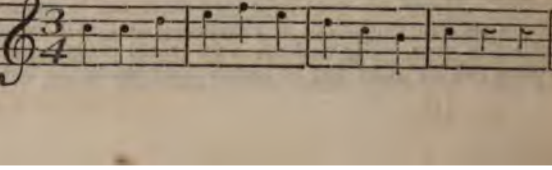
Grammatical accent is the emphasis, always slight, and indeed only just perceptible, given to notes which are in the accented parts of a bar (see *below*), and may be thus exemplified:—



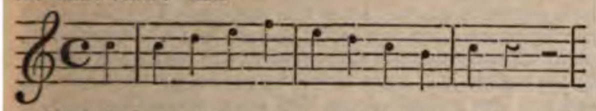
Now, without accent, these notes would have no measure, that is, would not be in any musical time; but if the first, fifth, and ninth are accented, the whole will be divided into bars of common, or equal, time. Ex.



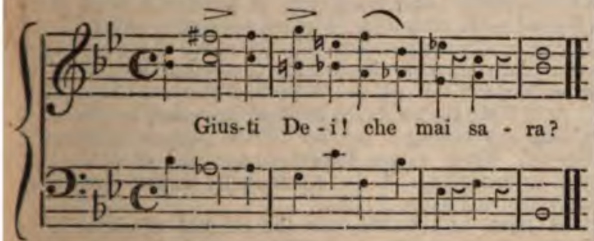
If an emphasis is given to the first, fourth, and seventh notes, the series will divide into bars of triple time. Ex.



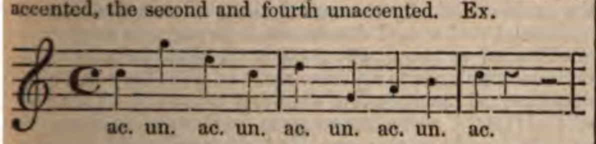
Again, an entirely different effect will be produced by throwing the accent on the first, third, fifth, &c., notes of the same series. Ex.



Oratorical accent is expression—is the accent dictated by feeling—and not confined to any particular part of the bar. It often is required, though the composer may not have marked it by any sign, but left it to the knowledge and taste of the performer to discover and enforce. Commonly, however, the terms *rinforzato* (strengthened), and *sforzato* (violently forced), are used for the purpose, though these participles are too often thought synonymous. An acute angle (>) is also employed to indicate such emphasis. The annexed passage, from Mozart's *Figaro*, is an example of oratorical accent, the stress being laid on notes in both the unaccented and accented parts of the bar, the words 'Giusti Dei!' (Just Gods!) demanding strong expression:—

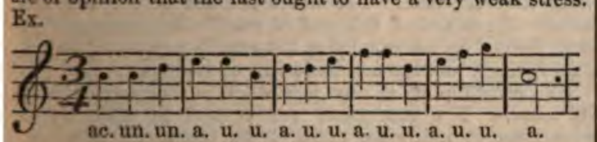


ACCENTED PARTS OF A BAR, in Music, are such as naturally require some emphasis. In common time, the bar of which is divided into four parts, the first and third are accented, the second and fourth unaccented. Ex.



If the movement is very slow, the accent will fall on the first, third, fifth, and seventh parts,—on every other quaver.

In triple time of three crotchets, the accent is on the first; the second and third are unaccented. Though some writers are of opinion that the last ought to have a very weak stress. Ex.



In three-quaver time the accent is on the first quaver only. In six-quaver time, it is on the first and fourth quavers. Nine-quaver and twelve-quaver times, which are only multiples of the two former, follow the same rule as those. The extremes, however, of slowness and quickness in times, though not altering their names, change the number of accented parts. Thus, as we have before remarked, each bar of common time in an *adagio* (a very slow movement) has four accented parts; and when six-quaver time is very rapid, or *presto*, the first note in each bar is alone accented. The various times (as well as the many clefs) ought to be reduced in number, by which the laws of accent might be much simplified, and confined to two very plain rules. [See CLEF and TIME.]

ACCEPTANCE. [See BILL OF EXCHANGE.]

ACCESSARY (from the low Latin *accessorius vel accessorium*), is, in law, one who is guilty of a felonious offence, not as chief actor, but as a participator without being present at the time of the actual committing of the offence, as by command, advice, instigation, or concealment, &c.

A man may be accessary either before the fact, or after it.

An accessary *before the fact* is defined by Lord Hale to be one who, "being absent at the time of the crime committed, doth yet procure, counsel, or command another to commit a crime." The absence of the offender is necessary to constitute him an accessary, as otherwise he would be a principal; and he must have procured the commission of the crime, either by direct personal communication with the actual perpetrator, or by conveying his advice or command through some indirect channel. But the mere concealment of a felony intended to be committed, without actual instigation, will not make a man an accessary; as that is only a misprision of felony. It is an established rule, that where a man commands another to commit an unlawful act, he is accessary not merely to the act commanded, but to all the consequences that may ensue upon it, except such as could not in any reasonable probability be anticipated or feared: as, for instance, if he commands another violently to beat a third person and he beats him so that he dies, the person giving the command is guilty as accessary to the murder consequent upon the act, notwithstanding that it may never have been his intention that a crime of so deep a dye should be committed. But a man will not be guilty as accessary before the fact if he command another to kill A, and he kills B, knowing that it was not A, because the particular crime he contemplated has never been completed. It is otherwise where the directions have been *substantially* pursued, although the crime may not have been committed precisely in the *manner* in which it was commanded to be done, as where a murder is effected by means of stabbing instead of poisoning.

An *accessary after the fact* is one who, knowing that a man has committed a felony, receives, relieves, or assists him. In general, any assistance given to a felon to hinder his being apprehended, tried, or suffering punishment, as by affording him the means to escape the pursuit of justice, will constitute the assister an accessary after the fact; but it is not so if the assistance given have no such tendency, as when clothes or necessaries are supplied to a felon in gaol. Although any *act done* to enable the criminal to escape the vengeance of the law will make a man guilty as accessary after the fact, a mere omission to apprehend him, without giving positive assistance, will not have that effect. Also, if the crime be not completed, at the time of the relief or assistance afforded, the reliever or assister is not adjudged an accessary to it; as where a mortal wound has been given, but the murder is not then consummated by the death of the party: yet, the crime once complete, not even the nearest ties of blood can be pleaded in justification of concealment or relief, except alone in the case of a wife, whom the law supposes to be so much under the coercion of her husband, that she ought not to be considered as accessary to his crime, by receiving him after it has been committed.

By the late statutes of 7 and 8 George IV., the punishment of accessaries before the fact is assimilated to that which is by law inflicted on the principal; and accessaries after the fact are made punishable with imprisonment proportioned to the heinousness of the original crime, but in no case is the imprisonment to exceed two years. The offence of receiving stolen goods is by those statutes specially provided for, and those who are convicted of it are made liable to fourteen years' transportation.

Formerly no accessary could be tried until after the conviction of the principal, the crime of the former being regarded as, in a manner, dependent on that of the latter; but in the present day the law is greatly altered in this respect. It is now competent to try and convict him, either as accessary, or for a distinct substantive felony, without waiting for the conviction of the principal, who may not be within the reach of justice, or who may, perhaps, have been acquitted through accidental failure of evidence.

It remains to be observed, that the distinction between principals and accessaries holds only in cases of felony.

ACCIDENT, see PREDICABLES.

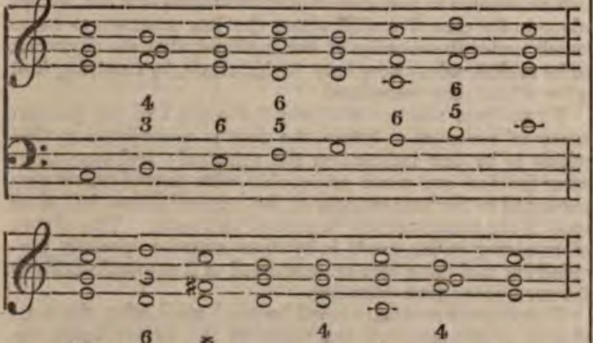
ACCIPENSER, in Zoology, a genus of fishes. [See STURGEON.]

ACCOLA'DE. This French word, derived from the Latin *ad*, to, and *collum*, the neck, signifies, in familiar speech, an embrace; and this idea, or that of union by means of the neck, as when two oxen are yoked together, is that which prevails in various other derivatives from the same root, both in the French and Italian languages. Some, accordingly, have supposed that, when used as descriptive of a certain part of the ancient ceremony of conferring knighthood, the particular act which it denoted was the *embrace*, accompanied with a kiss, which was bestowed upon the new-made knight, in token of the brotherhood established between them by his admission into the order of chivalry. It has, however, been the more generally-received opinion, that the accolade was what we call in English (though perhaps improperly) the dubbing, the slight blow given to the cheek or shoulder of the knight, 'as an emblem,' to use the language of Gibbon, 'of the last affront which it was lawful for him to endure.' There is no doubt as to the great antiquity of this last-mentioned custom. Gregory of Tours, writing in the sixth century, describes the blow on the shoulder as part of the ceremony with which the kings of France, of the first race, were wont to confer the honour of knighthood. It has been derived, by some antiquaries, from the blow which the Roman slave received from his master when manumitted, or made a freeman. The blow of liberation, indeed, whatever may have been its original import, may be traced in various directions among the usages of the middle ages. In Germany, up to comparatively recent times, noblemen were wont to confer upon a slave the right of bearing arms by striking him. The act was called *wehrhaft machen*, that is, to make him capable of bearing arms. And in the same country it is still, in many places, the practice for the apprentice to receive a blow from the oldest journeyman when, by the termination of his apprenticeship, he becomes a freeman, and a member of the guild. The blow by which knighthood was conferred seems to have been originally given with the hand, for which the flat part of the sword was afterwards substituted.

ACCOMPANIMENT, in Music, is the subordinate part, or parts, accompanying a voice, or several voices, or a principal instrument, &c. The piano-forte or guitar part of a song is the accompaniment, the air itself being the principal, the other only the useful ally, the support. In a concerto the whole band accompany the instrument for which the chief and prominent part is composed, except in the *tutti* parts, (*i.e.*, those portions of the concerto in which the principal instrument rests,) then the orchestral parts take the form of a full piece.

Accompaniment is also the harmony of a figured base, or another word for what is, by a foolish, unmeaning term—but too generally adopted to be at once discarded—called *thorough-base.*

The *Accompaniment of the Scale* is the harmony assigned, partly by what may be called nature and partly by custom, to that series of notes denominated the *diatonic scale* ascending and descending, such scale being taken as a base. Ex.



The diatonic scale adopted as a melody has one simple accompaniment, consisting almost exclusively of common chords; but it is also susceptible of many different harmonies, the study of which is of the utmost importance to the singer, as well as the accompanist and composer. [See DIATONIC SCALE.]

Dr. Burney (in Rees' *Cyclopædia*) seems very much inclined to favour the opinions concerning accompaniment which Rousseau endeavoured to propagate in his *Lettre sur la Musique Française*. This acute French writer, the zealous defender of the Italian school when, as relates to dramatic music, it certainly was the best, thinks that an accompaniment of the smallest possible number of notes is to be preferred; and he appears to have been enraptured by a little boy who, at the performance of an Italian burletta in Paris, accompanied, on the harpsichord, the airs with harmony of the most meagre kind, sometimes playing with only two fingers. Rousseau had not acquired a taste for rich harmony, for with the music of the German school he was very little, if at all, acquainted; but that our celebrated and generally very judicious English writer, to whom the finest compositions of Germany were well known, should have sanctioned opinions formed upon the imperfect knowledge of the subject existing in the middle of the last century, is somewhat a matter of surprise; and as Dr. Burney is an authority, it is more necessary, for the sake of the art, to demur to his judgment here. *Est modus in rebus*—and sensible accompanists well know this medium. The old Italian accompaniment can now hardly be endured; while, certainly, many ultra-Germanists of the present day overpower melody by the multitude of notes which, for want of sound judgment, and in a true pedantic spirit, they are so prone to employ.

ACCOMPTS.—[See BOOK-KEEPING.]

ACCOUNT or **ACCOMPT** (from the low Latin *Computus*), is a form of action which in the earlier times was much resorted to, and of which frequent mention is made in the old law books. Strictly, it lay only against a bailiff or receiver, requiring him to render an account of the moneys received by him as such bailiff or receiver; but the form of action being found to be one of the most convenient at that time, it was extended to cases where the person called upon to account was neither a bailiff nor an authorized receiver, if he had in any way received and retained money which it was his duty to have handed over to the claimant. At present the action of account is rarely used, a bill in equity being found to be in practice a much more effectual mode of settling disputed accounts; whilst in the other cases formerly embraced by the action of account, various modern and more simple forms of proceeding are adopted in preference to this, which is difficult, dilatory, and expensive.

ACCUMULATION, in Political Economy, is the act of adding one *Saving* to another for the purpose of forming *Capital*. Every saving indicates an excess of production over consumption, and the accumulated excess constitutes individual and national riches.

In 1832, 14,311,647*l.* was the amount of deposits in Savings-Banks in England, Wales, and Ireland, made by 429,400 depositors. This large capital was an accumulation, penny by penny, shilling by shilling, and pound by pound, of the savings of that class of persons who, in every country, have the greatest difficulty in accumulating. Habitual efforts of self-denial, and a rigid determination to postpone temporary gratification to permanent good, could alone have enabled these accumulators to retain so much of what they had produced beyond the amount of what they consumed. This sum of 14,311,647*l.* represents as many products of industry as could be bought by that sum. It is a capital which remains for the encouragement of *productive* consumption; that is, it is now applied as a fund for setting others to produce,—to enable them to consume while they produce,—and in like manner to accumulate some part of their productions beyond what they consume. The whole amount of our national riches—the capital of this, and of every other country—has been formed by the same slow but certain process of individual savings, and the accumulations of savings.

The consumption of any production is the destruction of its value. The production was created by industry to administer to individual wants, to be consumed, to be destroyed. When a thing capable of being consumed is produced, a value is created; when it is consumed, that value is destroyed. The general mass of riches then remains the same as it was before that production took place. If the power to produce, and the disposition to consume, were equal and constant, there could be no saving, no accumulation, no capital. If mankind, by their intelligence, their skill, their division of employments, their union of forces, had not put themselves in a condition to produce more than is consumed while the great body of industrious undertakings is in progress, society would have been stationary,—civilization could never have advanced. Whatever is consumed by those who are carrying forward the business of production, is called *productive* consumption. Whatever, on the other hand, is consumed by those who are not engaged in re-producing, is called *unproductive* consumption.—1. A shoemaker, we will say, rents a shop, works up leather and other materials, uses various tools, burns out candles, and is himself fed and clothed while in the act of producing a pair of shoes. This is productive consumption;—for the pair of shoes represents the value of the materials employed in them, the commodities consumed by the shoemaker during their production, and the wear and tear of the tools applied in making them. If the shoes represent a higher value than what has been consumed, in consequence of the productiveness of the labour of the shoemaker, the difference is *net* produce, which may be saved, and with other savings, become capital.—2. The shoemaker, we will suppose, accumulates profits sufficient to enable him to live without making shoes, or applying himself to any other branch of industry. He now uses no materials, he employs no tools, but he consumes for the support and enjoyment of existence, without adding anything to the *gross* produce of society·—this is unproductive consumption. It would be well to note, however, that there may be direct production, and indirect production. The shoemaker is an example of the one case ;—the man of science, who enlarges the bounds of human knowledge, and thus enables others to produce more successfully, is an example of the other. [See CONSUMPTION.]

Accumulations merely hoarded up, and not put to use, have been denominated savings: when they are applied to the encouragement of production, they are capital, and are capable of producing profit. The savings of the artisans, domestics, and labourers, who make up the depositors in savings banks, are capital, and produce profit to the accumulators, in the shape of interest. If a man is engaged in manufactures or trade of any sort, his savings can be readily invested as capital; because every saving applied to his own branch of production enables him to extend the quantity of what he produces. If his savings exceed the demands of his business, he lends a portion of his capital, either directly or indirectly, to some other producer, who pays him a part of his profits as interest. Those who derive their income from revenue, and not from profit or labour, either consume as much as they receive, or they accumulate more capital. Whatever they save is—like every saving of every class—a clear addition to the general riches, and a means through which productive takes the place of unproductive consumption.

Whatever is saved and accumulated is a saving and accumulation of commodities which have been produced. The value of the accumulation is most conveniently expressed by an equivalent in money; but only a very small part of the accumulation is actually money. A few millions of bullion are sufficient to carry on the transactions of this country; its accumulations, or capital, could not be purchased by several times the amount of all the bullion that exists in the world. A great part of what is saved, therefore, is an accumulation of products suitable for consumption. The moment that they are applied to the encouragement of production, they begin to be consumed. They encourage production only as far as they enable the producers to consume while they are in the act of producing. Accumulation, therefore, is no hindrance to consumption. It encourages consumption as much as expenditure of revenue unaccompanied by accumulation. It changes only unproductive into productive consumption; it enables the things consumed to be replaced, instead of being utterly destroyed. The manner in which this effect is brought about requires to be shown a little in detail; and we may probably make the subject clearer if we exhibit the influence upon society of the conduct of three different individuals, each of whom may be taken as examples of a class.

1. The prodigal, who utterly destroys the accumulated property which the labours of others have created, is, fortunately, an exception to the general mass of consumers. As mankind have become more instructed, they have been less disposed to look with complacency upon the career of such an individual. Even amongst ill-informed people, it is not uncommon to hear it said of such an unhappy person, that he has eaten his estate. It is not, of course, meant by this expression that his house or his lands are actually consumed; but, though the house and lands remain, something equal in value has been destroyed by his extravagance. He mortgages or sells his house or lands; and the proceeds of the sale are consumed by riotous companions, by thoughtless domestics, by ministers to his sensual passions, by the persons who have been engaged in preparing for him foolish gratifications. The capital which has bought his house and lands has been withdrawn from productive consumption. It was employed, we will say, in a particular species of manufacture; and the workmen whom it called into action were accustomed to consume in the most advantageous way for production, whilst they were themselves reproducing. The capital is withdrawn from manufactures to support the consumption of a number of persons whose command of the means of consumption will soon be at an end; and whose consumption, while it lasts, is so capricious, that no regular branch of industry can address itself to its supply. The productive consumers, who were maintained while the capital was engaged in manufactures, lose their employment; they become competitors in the market of labour; their competition diminishes wages; and the whole body of productive consumers in their department of industry are compelled to consume less. The unproductive consumption of the prodigal goes on till he can consume no longer. The value of his estate is utterly destroyed; it is so much completely wasted of the general capital. If all capitalists were to pursue the same course as the prodigal, in less than a generation the most civilized country would return to a state of the most helpless barbarism. There would be no fund for the maintenance of labour. Adam Smith says of the man who encroaches upon his capital, 'By diminishing the funds destined for the employment of productive labour, he necessarily diminishes, so far as it depends upon him, the quantity of that labour which adds a value to the subject upon which it is bestowed, and, consequently, the value of the annual produce of the land and labour of the whole country, the real wealth and revenue of its inhabitants.'

2. The proprietor who systematically consumes his revenue, without taking from or adding to his capital, is not a public enemy, as the prodigal is, but he is certainly not a public benefactor. As far as the mere act of consumption goes he destroys without reproducing. But he may consume to the full extent of his income, furnishing no funds for reproductive consumption, without any fault of his own; and, in some respects, he may accumulate whilst he consumes, so as to enable others to consume profitably. If he have children whom he trains to manhood, bestowing upon them a liberal education, and causing them to be diligently instructed in some calling which requires skill and experience, he is an accumulator. By the capital thus spent in enabling his children to be producers, he has accumulated a fund out of his consumption which may be productive at a future day. He has postponed his contribution to the general stock; but he has not withheld it altogether. Speaking generally, however, of the class who consume all their income, we may be warranted in saying that the encouragement which they afford to industry never advances, because there is no accumulation to give employment to new industry. A man who receives a thousand a year, and spends it, may give employment to twenty men; but, after he has spent this sum for twenty years, he will, in the twentieth year, give employment only to the same number of men that he did in the first year. The fund which sets the labourers in action cannot increase, and therefore the labourers cannot increase, because the amount of labour to be performed cannot increase. If the labourers increase beyond the labour, they each labour less, and are each worse paid.

3. Let us take a capitalist with an income of a thousand a year, who consumes three-fifths of that income unproductively, and employs two-fifths in productive consumption. By his unproductive consumption of six hundred a year, twelve men are maintained, taking the proportion of the former case. By his productive consumption of four hundred a year, either in agricultural or commercial undertakings, or by lending the money to others, he employs eight men. The effect of the expenditure upon labour is so far equal in this case and the former. But when a profit is made, there is an essential difference; for if twelve and a half per cent., or fifty pounds profit, is annually made upon the four hundred pounds, there is a fund created for the constant employment of another labourer. The twelve and a half per cent. profit upon the profit, in five or six years, enables a second additional labourer to be employed, and so on. It is in this way that profits, gradually accumulated, enable the number of labourers to increase; and thus in all countries where capital is saved for productive consumption, the population may be doubled, and the larger number be yet better fed, and lodged, and clothed, than the smaller.

The accumulations of a nation, in its collective capacity, must be determined by the extent of individual accumulations. National accumulations facilitate individual, by rendering industry easier and more effective. They are exhibited in the form of roads, canals, harbours, docks, bridges, water-works, public buildings, endowments for education. These facilities for accumulation follow the accumulations of individuals, although a feeble accumulation may be rendered powerful by a judicious expenditure upon a great public object. The formation of a road, for instance, through an agricultural district, by opening a market, may enable the agriculturists to accumulate various savings arising out of that ready communication.

Whatever tends to enlighten the great body of the people facilitates individual accumulation. A large portion of the productions of industry, especially amongst the humbler classes of the community, is wasted, in addition to that portion which is enjoyed. Every consumption that is saved by habits of order, by knowing the best way of setting about a thing, by economy in the use of materials, is so much saved of the national capital; and what is saved remains to give new encouragement to the labour of the producer, and to bestow an increase of comforts upon the consumer. Again, the more that professional skill of every sort is based upon real knowledge, the more productive will be the industry of every class of labourers. Above all, sound morals, and pure and simple tastes, are the best preservatives from wasteful expenditure, both in the rich, and in the poor; and he that limits his individual gratification to objects worthy of a rational being, has the best chance of acquiring a sufficiency for his wants, and of laying by something to provide a fund for that productive consumption by which the wants of others are supplied. [See Smith's *Wealth of Nations*, Book ii. chap. iii. Say, *Cours Complet*, tom. i. chap. xiii. and xiv. M'Culloch's *Principles*, Part I. chap. ii. § 3. Mill's *Elements of Polit. Ecom.* chap. iv. § 1.]

ACCUSATIVE CASE, a term used in the grammatical system of the Latin language, and thence unnecessarily introduced into that of the English language. In Greek this case is not called *accusative*, but the same idea is expressed by a corresponding term in that language. In the article *ablative case*, the meaning of the word *case* was explained. In that article it was seen that the little syllable *em* is attached to the end of Latin nouns, and has the meaning of *motion to*. But where the simple Latin noun terminated in a vowel, the *e* of *em* was absorbed by that preceding vowel. Thus, to take an example, *Roma* was, and is, the name of the Roman capital, though, by Englishmen, generally corrupted into *Rome;* consequently, *to Rome* was expressed by *Romam* (a contraction from *Roma-em*)*;* so, *in Romam*, expressed *into Rome*. *In Roma*, without the *m*, would signify merely *in Rome*. The accusative then signifying, originally, the object to which any motion is directed, was afterwards, by a very natural metaphor, employed to distinguish the object of any action or feeling; thus, *incendere Romam, to burn Rome*. The Spanish and Portuguese have, in their languages, very closely imitated the Latin in this respect: *despidio de su casa à mi Dulcinea*—if translated word for word would be—he despatched from his house *to my Dulcinea;* but nothing more is meant than what we express by—he despatched my Dulcinea from his house. The *despatching* is with reference to Dulcinea. The employment of the letter *m*, with or without a weak vowel before it, occurs likewise in the Sanscrit language; and indeed in our own, in the pronouns *him* and *whom*, from *he* and *who*. The Greeks preferred the allied letter *n*, which is also found in some classes of the German nouns, as *den Grafen, the Count*, from the nominative *der Graf*. When the term *accusative case* is used in the grammar of our own language, it is only in this second or metaphorical sense, and, consequently, it is equivalent to what many grammars call by the better name of the *objective case*, or more simply the *object*.

ACER, a name given by the Romans to the tree called maple by the English. It is now applied to a genus of arborescent or shrubby plants, many of which are extremely valuable, for the sake either of their timber, or of their ornamental appearance. As they are for the most part hardy, we shall enumerate all the species that are known, giving characters to the most remarkable only. In order to assist the reader in distinguishing them, we have added figures, on a reduced scale, of the leaves of the more important kinds.

Acer is also the principal genus in the natural order called ACERINEÆ; which see.

GENERIC CHARACTER.

Flowers green and inconspicuous, either containing stamens only, or pistilla only, or both united, upon the same individual.

Calyx divided into five lobes, of uncertain length.

Stamens occasionally five; more frequently varying from seven to nine.

Leaves in all cases simple.

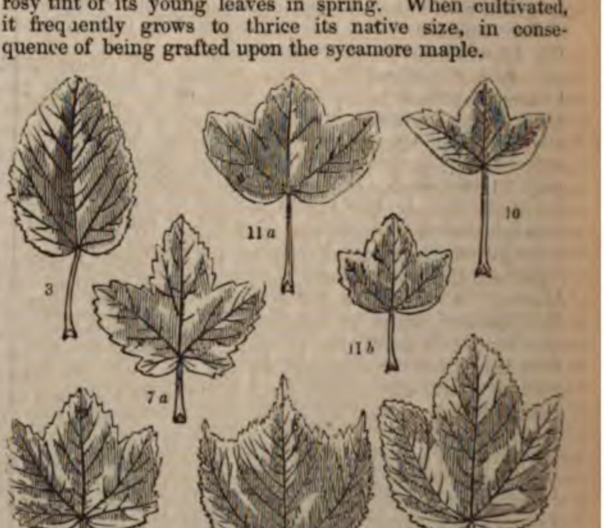
Fruit double; each division containing one single-seeded cavity, and extended at the back into a kind of wing; called *key* in English, or *samara* by botanists.

1. *Acer oblongum*, oval-leaved maple (*Wallich in De Cand. Prodr.* i. 593).—An evergreen tree, of rapid growth, native of the northern parts of India, both in Nepaul and Kumaon. It is probably confined to the hot valleys of those regions, for it has been found incapable of supporting the climate of England. Its leaves are six or seven inches long, without any divisions, of an ovate figure, tapering into a narrow point; they stand upon slender foot-stalks, and are smooth and glossy above; beneath they are covered with a slight bloom, and are finely netted. The keys are nearly parallel with each other.

2. *Acer lævigatum*, the polished maple (*Wallich, Pl. as. rar.* 2. 3. t. 104). Leaves oblong, taper-pointed, slightly serrated, shining, green beneath. Flowers white, in branched erect thyrses. Keys broad, short, smooth.—Found in the woods of the higher mountains of Nepaul, and also in the Alps of Sirmore, where it acquires a trunk thirty or forty feet high, and from three to four feet thick. Its growth is slow; its timber is said by Dr. Wallich to be used by the inhabitants of Nepaul for rafters, beams, and similar building purposes.

3. *Acer Tataricum*, the Tartarian maple (*Linn. Sp. pl.* 1495). Leaves heart-shaped, oblong, unequally serrated, usually undivided; the veins downy beneath. Flowers in short, erect, branched racemes. Keys diverging a little, rounded at the point.—An ornamental tree, or rather large bush, from fifteen to twenty feet high, often met with in gardens and plantations. Its native countries are the southern provinces of Russia in Asia, whence it extends as far as Hungary, there finding its most western limit. The Calmucs call it *zarza-modon*, or *locust-tree;* from its keys, deprived of their wings, they form, by the aid of boiling water, an astringent beverage, which, mixed with an abundance of milk and butter, forms a favourite article of their diet. The wood is hard and white, mixed with brownish veins.

4. *Acer striatum*, the striped-bark maple (*Lam. Dict.*, 2. 381. A. Pennsylvanicum, *Linn.* A. Canadense, *Du Ham*). Leaves roundish, finely serrated, divided at the upper end into three nearly equal tapering lobes; when young covered with a mealiness, which is gradually thrown off as they increase in size. Flowers in drooping racemes. Keys short, blunt, diverging. Bark striped with black and gray.—A native of North America, from Canada to the high lands in Georgia. In those countries it forms a considerable part of the undergrowth of the woods, among sugar-maples, beeches, birches, and hemlock-spruce firs. It rarely exceeds eight or ten feet in height, except in a few very favourable situations, when it will occasionally grow double that height. Its wood is very white, and is used by the North Americans for inlaying cabinet-work; its shoots afford food to various animals, especially to the moose-deer, in winter and spring, whence it has acquired the name of *moose-wood*. In Europe it is occasionally seen in plantations, where it is remarkable for the bright rosy tint of its young leaves in spring. When cultivated, it frequently grows to thrice its native size, in consequence of being grafted upon the sycamore maple.



3. A. tataricum. 11a and b. A. creticum.
10. A. monspessulanum. 7a. A. opulus. 8a. A. obtusatum.
4. A. striatum. 5. A. barbatum.

5. *Acer barbatum*, the bearded maple (*Mich. Fl. Am. bor.* 2. 252). Leaves heart-shaped, three-lobed, nearly equally serrated; the lobes of nearly equal size, or the lateral ones much the smallest; nearly smooth beneath. Clusters sessile; the stalks of the female flowers simple, of the male flowers branched. Calyx bearded internally. Keys smooth, diverging but little.—This rare and little-known species is a native, according to Pursh, of deep pine and cedar swamps in Jersey and Carolina, where it forms a small tree. Nothing is known of its useful application, if any. In the nurseries it is generally called A. trilobatum.

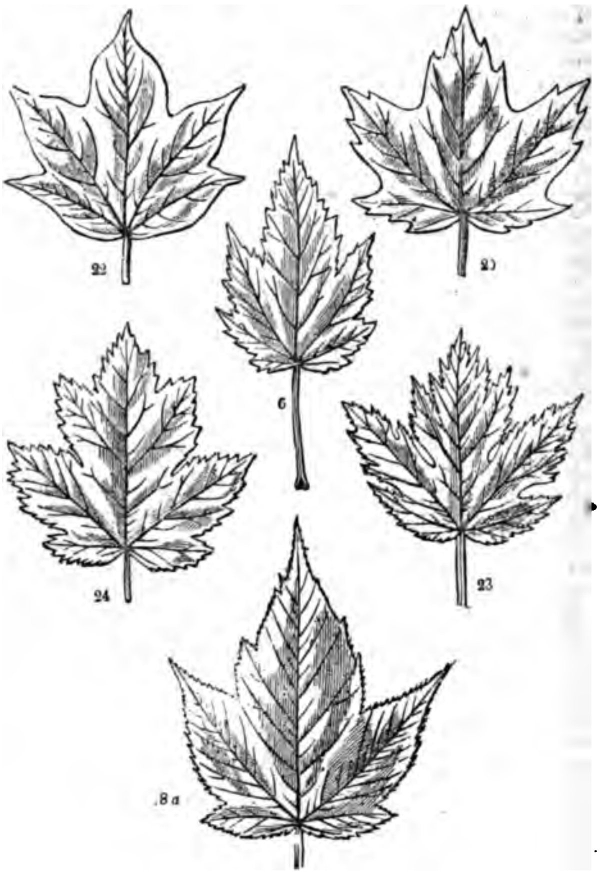
6. *Acer spicatum*, the spike-flowered maple (*Lam. Dict.*, 2. 381. A montanum, *Ait.*). Leaves heart-shaped, smooth above, downy and glaucous beneath, of an oblong figure, with about five unequal, tapering, coarsely and unequally serrated divisions. Flowers small, green, in upright racemes. Keys short, rounded, a little diverging.—A small tree, of rather inelegant appearance, found on mountains in the United States and in Canada. It is frequently seen in plantations in this country among other exotic trees. The red colour of its keys in the autumn forms its principal merit.

7. *Acer opulus*, the Gueldres-rose-leaved maple (*Ait. Hort. Kew*, 3. 436. A. rotundifolium, *Lam.* A. opulifolium, *Villars*). Leaves more or less heart-shaped, roundish, five-lobed, smooth beneath; the lobes generally obtuse, and coarsely serrated. Flowers in drooping corymbs. Keys smooth.—A small tree, ten or twelve feet high, found in France, especially in Dauphiny, where they call it *ayart*, and also in Spain. It is, in some respects, like *A. obtusatum*; but is readily known by its leaves being smooth beneath, and is far inferior to that noble species. It is not uncommon in botanical collections. Its leaves are sometimes very round, and sometimes have the lobes tapering; both are figured.

8. *Acer obtusatum*, the Neapolitan maple (*Willd. Sp. pl.* 4. 984. A. Neapolitanum, *Tenore*). Leaves heart-shaped, roundish, five-lobed, woolly beneath; the lobes either obtuse or pointed, and coarsely serrated. Flowers in drooping corymbs. Keys smooth.—Hungary, Croatia, and many parts of Italy, produce this beautiful species. On all the hills and lower mountains of the kingdom of Naples; in Camaldoni, Castellammare, and the Abruzzi, it is found abundantly, growing usually to the height of forty feet; it is extremely striking, with its reddish-purple branches in the wood of Lucania, between Rotonda and Rubia; and in the Basilicate and Calabria it is said, by Tenore, to acquire colossal dimensions. It is certainly very singular that so fine a tree as this, occupying so large a tract of country, frequently visited by English tourists, should be almost unknown in this country; and yet, although it is perfectly hardy, and very easily multiplied, it is scarcely ever met with in any but botanical collections. Two forms of the leaf are figured, one with blunt, and the other with pointed lobes.

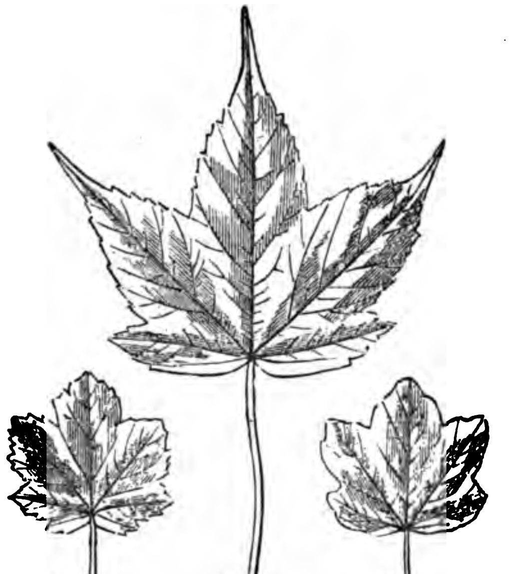
9. *Acer campestre*, the common maple. (*Linn. Sp. pl.* 1497.) Leaves heart-shaped, with three or five deep segments which are not serrated, but generally two or three-lobed, and narrow at their base; downy beneath, at least when young. Branches covered when old with a corky bark. Flowers in erect, branched, downy corymbs. Keys short, smooth, with nearly parallel edges, diverging at right angles.—Such appears to be the most general character of this very common species, found in every hedge-row in England, and spread over the greater part of Europe. It is said not to be indigenous in Scotland, and on the Continent it does not approach the north nearer than the southern provinces of Sweden. It advances as far to the eastward as the range of the Caucasus, where it disappears. In England this is either a bush or a small tree, of inelegant appearance, and its wood is of little value, except for the use of the turner, who makes it into cups, bowls, &c.; in the southern region of Caucasus, we are told by Pallas that it becomes a tree of handsome aspect, with a trunk as thick as a man's body, and that its wood is so hard as to be in request for the manufacture of musket-stocks: it must, however, be remarked, that this writer states the keys of his plant to be covered with down; it is, therefore, to be suspected that the Caucasian plant is distinct from our maple, in which the keys are always smooth. It is much to be wished that this point, which is of some importance, were cleared up. The common maple is sometimes planted by farmers upon bad land, for the purpose of fencing, for which, however, it is ill adapted.

There is a supposed variety of this, called *Acer austriacum*, found in the woods of Hungary and Austria, which has the segments of the leaves always broadest at the base, and scarcely lobed.



22. A. Lobelii. 20. A. saccharinum. 24. A. rubrum.
23. A. eriocarpon. 18a. A. caudatum. 6. A. spicatum.

10. *Acer Monspessulanum*, the Montpellier maple (*Linn. Sp. pl.* 1497. A. trilobatum, *Lam.* A. trilobum, *Mönch*). Leaves deciduous, very slightly cordate, and downy at the base, with three perfectly entire, nearly equal, diverging lobes, slightly hairy beneath. Flowers in small, loose, erect bunches, on long capillary stalks. Keys short, smooth, but little diverging.—Found in dry, stony situations in Languedoc, Dauphiny, Provence, and Piedmont; it even occurs as



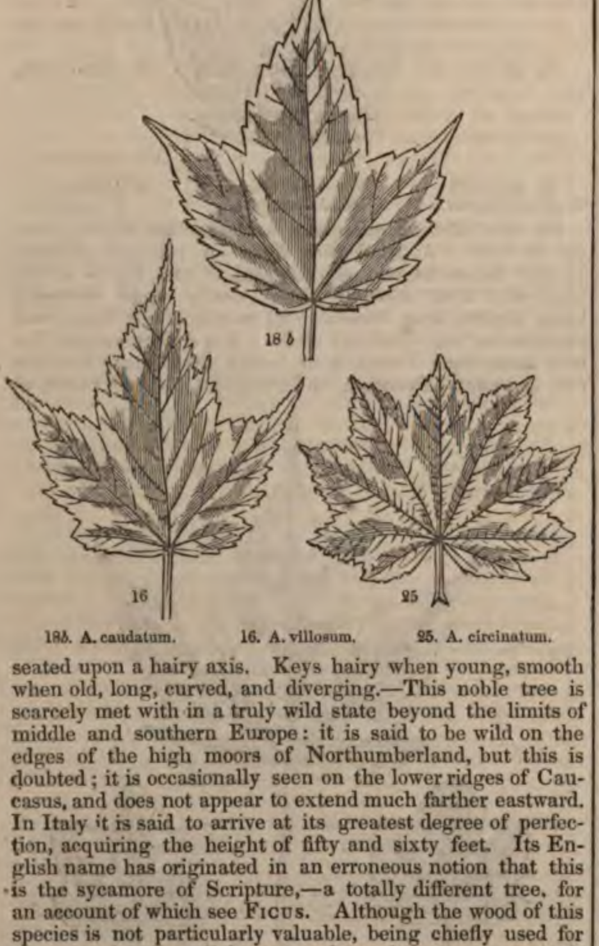
7b. A. opulus. 15. A. sterculiaceum. 8b. A. obtusatum.

far north as the departments of the Rhine. A small tree of rather handsome appearance, not uncommon in our shrubberies. It has in some respects the appearance of *A. campestre.* The little tuft of hair on the leaves at the point whence the principal veins radiate, is a good characteristic mark.

11. *Acer creticum,* the Candian maple. (*Linn. Sp. pl.* 1497. A. coriaceum, *Hort.*). Leaves evergreen, variable in form, wedge-shaped at the base, leathery, glossy, smooth, with three entire or serrated lobes, of which the side ones are the shortest, sometimes undivided. Flowers in small, erect clusters. Keys small, broad, but little diverging.—A very handsome evergreen shrub, or small tree, said to grow twenty feet high, found on the mountains of Candia and the Grecian archipelago; it is frequently cultivated in the South of Europe, but is apparently unknown in this country, being probably too tender to bear our winters. The plant usually called *A. creticum* in this country is *A. heterophyllum.*

12. *Acer heterophyllum,* the variable maple (*Willd. Arb.* 10. t. 1. f. 1). Leaves evergreen, ovate, unequally-serrated, entire or occasionally three-lobed, very glossy.—This is the plant sold in the English nurseries under the name of *A. creticum.* It is rather delicate, and is seldom met with in this country more than seven or eight feet high, when it becomes a scrubby bush, having little to recommend it except its rarity. No one has described either its flowers or fruit. It is a native of the Levant.

13. *Acer pseudo-platanus,* the sycamore maple (*Linn. Sp. pl.* 1496.) Leaves heart-shaped, coarsely and unequally serrated, glaucous and downy on the veins beneath; with five lobes, of which the lower ones are generally the smallest. Flowers in short, pendulous, slightly divided racemes, seated upon a hairy axis. Keys hairy when young, smooth when old, long, curved, and diverging.—This noble tree is scarcely met with in a truly wild state beyond the limits of middle and southern Europe: it is said to be wild on the edges of the high moors of Northumberland, but this is doubted; it is occasionally seen on the lower ridges of Caucasus, and does not appear to extend much farther eastward. In Italy it is said to arrive at its greatest degree of perfection, acquiring the height of fifty and sixty feet. Its English name has originated in an erroneous notion that this is the sycamore of Scripture,—a totally different tree, for an account of which see Ficus. Although the wood of this species is not particularly valuable, being chiefly used for coarse work, where lightness and toughness are required, yet there is scarcely any more universally cultivated for the sake of the striking effect it produces, whether as a single tree, or planted in avenues, or in masses. It thrives upon poor, sandy, or gravelly soil, especially near the sea, where few other trees will succeed; and will even bear the *smoke* of London, although not so well as some others, Many varieties are known to gardeners, of which the following are the most deserving notice.—



18b. A. caudatum. 16. A. villosum. 25. A. circinatum.

i. *The Red or Gold-striped.*—Leaves stained with yellow and red.

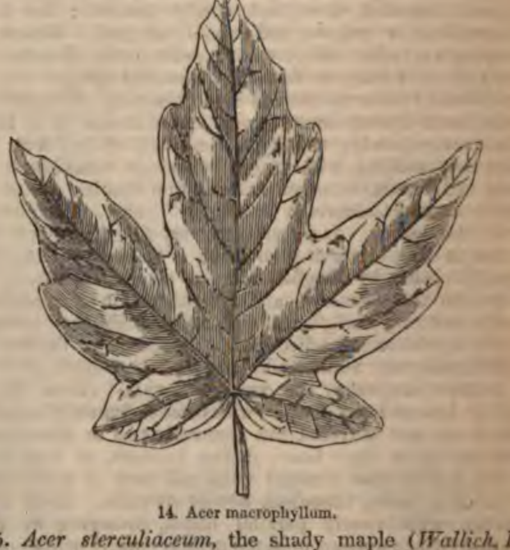
ii. *The Silver-striped.*—Leaves marked with streaks of white.

iii. *The Golden.*—Leaves having altogether a yellow tint.

iv. *The Corstorphine Plane.*—Distinguished by its broad leaves, and more vigorous mode of growth.

There is also found in the woods of Hungary, near Szánto, what botanists consider a variety, with the lower lobes of the leaves as large as the upper. By some this is called *A. palmifolium.*

14. *Acer macrophyllum,* the broad-leaved maple (*Pursh, Fl. Am. Bor.* 267). Leaves deeply heart-shaped, not serrated, divided into five deep, spreading, slightly-lobed segments, the middle one of which is often narrow at its base, and the lower ones generally smaller than the others; when young slightly downy, when old shining and perfectly smooth. Flowers in drooping very compact racemes, large, pale, yellowish green. Keys long, straight, diverging, covered at the base with long stiff hairs.—This species, which is probably the finest of the genus, has recently been procured in a living state, by the Horticultural Society, from the north-west coast of North America, where it forms a very large tree, having a dense umbrageous head, and yielding a timber apparently of considerable value; specimens of it, brought from North America, are scarcely inferior in beauty of the grain to the finest satin-wood. It proves to be a hardy tree, of very rapid growth, sometimes making shoots six or seven feet long in a season; and is remarkable for the unusual size of its leaves, some of which, on young vigorous shoots, have measured as much as ten inches in diameter.



14. Acer macrophyllum.

15. *Acer sterculiaceum,* the shady maple (*Wallich, Pl. as. rar.* 2. 3. t. 105). Leaves heart-shaped, downy on the under side, with five ovate, taper-pointed, serrated lobes, of which the lowest are very small. Flowers in very short drooping racemes.—A large tree, with a trunk often three feet in diameter; found in Nepaul, upon Mount Sheopore. It is not yet in England.

16. *Acer villosum,* the shaggy maple (*Wallich, Pl. as. rar.* 2. 4). Leaves heart-shaped, three-lobed, occasionally with two very obscure lateral lobes near the base, shaggy beneath; the lobes ovate, taper-pointed, remotely but equally serrated. Flowers in copious, nodding, shaggy, branched clusters. Keys downy.—A very large tree, found on the high Alps of India, approaching the limits of perpetual snow in Sirmore and Kumaon. This very distinct species is one of the finest trees in the north of India. It would, no doubt, prove hardy in this country, and it is much to be wished that it could be procured.

17. *Acer cultratum,* the curve-keyed maple (*Wallich, Pl. as. rar.* 2. 4).—A large tree, native of the regions towards the Himalaya, in Kamaon and Srinaghur.

18. *Acer caudatum,* the long-pointed maple (*Wallich, Pl. as. rar.* 2. 4.)—Native of the highest regions of Nepaul, towards Gossain Than, of Sirmore, Kumaon, and Srinaghur,

19. *Acer Platanoides*, the Norway maple (*Linn. Sp. pl.* 1496). Leaves heart-shaped, very smooth, except at the axillæ of the veins; five-lobed, the lobes taper-pointed and diverging, with a few taper-pointed diverging teeth. Flowers in loose, erect, stalked corymbs. Keys smooth, diverging.—A fine tree, with very handsome glossy deep-green leaves, for the sake of which it is a great deal cultivated. The northern and midland parts of Europe, and the north of Asia, as far as the Ural chain, produce this species. In the Russian empire it passes from the state of a shrub, in the northern provinces, to that of a handsome tree with a trunk two feet thick, in the more southern districts. Its wood is valued for turners' work; from its ascending sap a kind of coarse sugar has been procured, in the same way as from the *A. saccharinum*, in America. Two varieties are known to gardeners; one, *the silver-striped*, in which the leaves are slightly stained with white; and the other, the *cut-leaved*, in which the leaves are deeply and irregularly jagged. When the foot-stalks of the leaves are broken they exude a milky fluid.

20. *Acer saccharinum*, the sugar maple (*Linn. Sp. pl.* 1496). Leaves heart-shaped, glaucous beneath, very smooth, except at the axillæ of the veins; five-lobed, the lobes taper-pointed, and very coarsely toothed. Flowers in nodding corymbs. Keys not much diverging.—From a little to the north of Saint Jean, in Canada, to the woods of Upper Virginia, and probably still farther South, this species prevails; and it forms a large portion of the vegetation of New Brunswick, Nova Scotia, Vermont, and New Hampshire, sometimes becoming as much as eighty feet high. In the autumn the woods of those countries are dyed of a crimson hue, by the changing leaves of the sugar maple. The wood is hard, and has a satiny lustre, but it is readily attacked by insects, and is not of much value, except when its grain is accidentally waved, and then it is in request for the cabinet-makers. The younger Michaux states, that it may be at all times known from that of the red maple by a very simple test. If you pour a drop or two of solution of sulphate of iron upon the wood of the sugar maple, in a minute it becomes of a greenish cast, while that of the red maple becomes deep blue. The saccharine matter contained in its ascending sap is the principal cause of this species being in so much request. From this, obtained by tapping the trunk in the spring, during the space of six weeks, a very considerable quantity of a fine brown sugar is procured; as much, it is said, as 33 lb. per tree. The sugar maple does not generally succeed very well in England, where it is rarely seen; and even when in health is not more than fifteen or sixteen feet high.

21. *Acer nigrum*, the black sugar maple (*Michaux*, *Arb.* ii. p. 238, t. 16).—This plant is a native of similar situations with the last, of which perhaps it is only a variety. It differs, however, in having leaves of a deeper green, whence its name *black*, with their base much more heart-shaped, and much more downy beneath. It appears to possess the properties of the sugar maple, but in a very inferior degree.

22. *Acer Lobelii*, Lobel's maple (*Tenore Corso Botanico*, iv. 174). Leaves very slightly heart-shaped, imperfectly and irregularly toothed, divided into five shallow, abruptly-pointed lobes; quite smooth beneath, except at the point, whence the principal veins radiate. Keys smooth, very much diverging.—This is a large tree, in some respects not unlike A. Platanoides, with a perpendicular trunk, and a handsome pyramidal head. It is found among the mountains in the north of the kingdom of Naples; at Avvocata near Monte Vergine, Cerealto, Monte S. Angelo di Castellammare, &c.

23. *Acer eriocarpon*, Sir Charles Wager's maple (*Michaux*, *Fl. Am. sept.* ii. 253. A. dasycarpum, *Willd*). Leaves truncated at the base, glaucous and smooth beneath, deeply divided into five jagged, taper-pointed lobes. Flowers in thick clusters, without any petals. Keys large, green.—Found in most parts of North America on the eastern side, where it is commonly called *white maple*. It grows with great rapidity, especially on the banks of clear rivulets with a gravelly bottom, and is perhaps one of the most ornamental of the genus. It is extremely common in the plantations of all Europe, where it is remarkable for the deep crimson hue of its leaves in autumn. Its wood is light, and of little or no value except to the turner. It is said to make excellent charcoal for gunpowder. The height of this species often bears so little proportion to its other dimensions, that, according to the testimony of the younger Michaux, trees are found, especially at the mouth of the rivers Mononghahela and Alleghany, as much as fifteen feet in circumference of their trunk, without corresponding height. The nurserymen usually call this species the *cut-leaved scarlet maple*.

24. *Acer rubrum*, the scarlet maple (*Linn. Sp. pl.* 1496. A. coccineum, *Hort.*). Leaves slightly heart-shaped, glaucous beneath, divided into about three coarsely-toothed and lobed segments. Flowers clustered, with petals. Keys small, red.—The deep-red colour of the flowers in the spring, and of the keys and leaves in autumn, have given rise to the name of this species, which is found, from Canada to Florida, growing in swamps along with alders. With us it is one of the first trees that put forth their blossoms in the spring; and it is delightful to see its slender branches teeming with rosy life in the beginning of March, when almost all Nature is elsewhere still. Its wood is far more valuable than that of the *Acer eriocarpon*; it is not only constantly used by the Americans for articles of furniture, but is also in request for the stocks of rifles,—for which, when it is what they call *curled*, its toughness renders it well adapted. Two varieties of this species are cultivated in this country, under the names of *A. coccineum* and *A. intermedium*.

25. *Acer circinatum*, the curled maple (*Pursh*, *Fl. Am. sept.* i. 267). Leaves deeply cordate, roundish, divided into seven shallow, sharp-pointed, serrated lobes. Flowers in few-flowered corymbs.—On the north-west coast of North America this grows in company with A. macrophyllum. It is a small, scrubby, worthless tree. Specimens of it are growing in the garden of the Horticultural Society of London.

Besides the foregoing, the following are mentioned by botanical writers, but little is known of them.

26. *A. hybridum* (Bosc, Dict. Agr. 5.251). Origin unknown: cultivated in France.?

27. *A. obtusifolium* (Fl. Græca, t. 361). Found on the Sphaciote mountains of Greece.

28. *A. ibericum* (Bieb. Fl. Taur. Cauc.). A small tree, like A. monspessulanum: found in Iberia.

29. *A. dissectum* (Thunb. Jap. 160.)	All natives of Japan.
30. *A. Japonicum* (Ib. p. 161.)	
31. *A. palmatum* (Ib. l. c.)	
32. *A. septemlobum* (Ib. p. 162.)	
33. *A. pictum* (Ib. p. 162.)	
34. *A. trifidum* (Ib. p. 163.)	

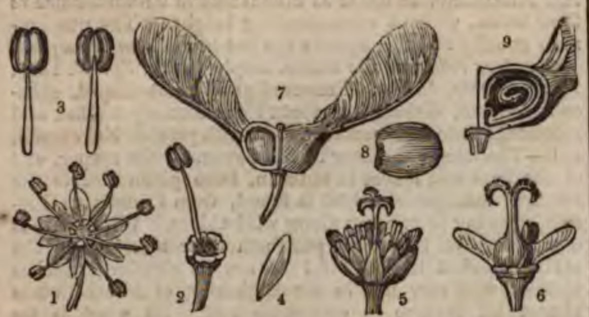
For A. Negundo, see NEGUNDO.

Cultivation.—The hardy maples, which are the only kinds of any importance in this country, are all increased either by seeds or layers. The European species readily yield their *keys*, which should be gathered when fully ripe, and immediately buried in heaps of river sand, where they may remain till the following February; they may then be sown in beds, rather thinly, and, when one year old, should be transplanted and treated like other forest trees. They ought never to be headed back, as oaks and Spanish chestnuts are. From layers they all make excellent plants very rapidly. They are occasionally budded upon the common sycamore, but this mode is little practised in England.

ACERINEÆ, a tribe of plants comprehending only the maples (see ACER) and the ash-leaved maples (see NEGUNDO). They belong to the Polypetalous division of the Dicotyledonous class, and are related to *Tiliaceæ*, or the Linden tribe: they are also akin to a tribe of tropical plants called *Malpighiaceæ*, which see. They are known—1. by their flowers being what is called unsymmetrical, that is, not having the various parts agreeing in number: for instance, while the calyx and corolla are divided each into five parts, there are seven, eight, or nine stamens, and three divisions of the pistillum—2. by their stamens being hypogynous, and inserted upon a disk—3. by their winged fruit, or *keys*—and, 4. by their petals having no appendages upon them. The species are all trees or shrubs, with opposite stalked exstipulate leaves, and are found exclusively in the north of Europe, Asia, America, and India. A sweet, mucilaginous sap is common in these plants, from which sugar can be manufactured.

CHARACTER.

Flowers either unisexual (1) or bisexual (5). Calyx and corolla (1) equal in the number of their parts, with an imbricated æstivation; the corolla sometimes absent. Petals (4) without appendages; stamens (3) hypogynous, inserted upon a disk (2.6), which arises from below the pistillum, not agreeing in number with the divisions of the calyx and corolla. Pistillum (6) two-lobed, each lobe having a wing at its back. Style one. Stigmata two. Fruit (7) formed of two samaræ, or keys, with long wings at their back, each containing one cell and one erect seed (8). Embryo (9) curved, with leafy, shrivelled cotyledons, and no albumen. Trees or shrubs, with opposite leaves, without stipulæ.



ACE'TATE, a salt resulting from the combination of the acetic acid with an alkaline, earthy, metallic, or vegeto-alkaline base. The acetates are prepared in different modes, according to circumstances; and indeed the same acetate may frequently be made by various processes. The acetate of soda, which is an alkaline acetate, may be formed, though not advantageously, by single affinity, or saturating the acid with the caustic soda: the acetate of lime, an earthy acetate, is easily procured by single elective affinity and decomposition, as when carbonate of lime (chalk) is added to the acid as long as it will dissolve; and the acetate of zinc, which is a metallic acetate, may be obtained by mixing a solution of acetate of lead with one of sulphate of zinc: in this case acetate of zinc is produced by double elective affinity and decomposition. All acetates, and indeed all salts whatever, are the result either of single, single elective, or double elective affinity.

It follows, from what has been stated, that the acetates may be divided into four classes,—namely, the alkaline, earthy, metallic, and vegeto-alkaline acetates; as an example of each, and in the order mentioned, the following may be enumerated:—acetate of soda, lime, lead, and morphia.

Although the classes of acetates possess some properties in common, yet, from the very different nature of their bases, it can hardly be expected that the points of agreement should be numerous. Thus, the acetate of ammonia is evaporable by heat, whilst the other alkaline acetates are not merely decomposed at a high temperature, but the acid itself undergoes this change, and its carbon and oxygen, or a portion of them, recombine so as to form carbonic acid; and some acetates, that of soda for example, are converted by heat into carbonates. Many of the earthy acetates suffer similar changes; thus, the acetate of lime is reduced by heat to a carbonate, but if the heat be long continued, and stronger than required for the formation of the carbonic acid, the carbonic acid is subsequently expelled, and pure lime remains instead of the carbonate.

Some of the metallic acetates, when subjected to distillation at a high temperature, yield a large portion of acetic acid of considerable purity. This is the case with the acetate of silver, and also with that of copper, after it has been redistilled. But there are other metallic acetates—as the acetate of lead and of zinc—which, besides acetic acid, furnish a peculiar volatile inflammable fluid called pyro-acetic spirit: this is derived from the decomposition of a part of the acetic acid, and the recombination of its elements in different proportions. In general those acetates which are easily decomposed give most acetic acid and least pyro-acetic spirit, and *vice versâ*.

In the retort in which the metallic acetates are decomposed by heat during distillation, their bases, in some instances, remain in the metallic state. This happens with the acetates of copper, lead, and silver; while the acetates of iron, manganese, and zinc leave the bases in the form of oxide: in both cases the residue is mixed with charcoal, which results from the decomposition of a portion of the acetic acid; and, derived from the same source, there are evolved carbonic acid gas, and carburetted hydrogen gas.

The vegeto-alkaline acetates, such as those of morphia, quina, &c., are decomposed and totally dissipated when exposed to heat in open vessels. As the affinity existing between the acetic acid and the bases with which it combines is but weak, all acetates are decomposed by the more powerful acids. On this circumstance depends the preparation of acetic acid from some acetates, especially those of soda and lime, by the action of sulphuric acid (oil of vitriol). This stronger acid unites with the bases, and expels the acetic acid, which is condensed in proper receivers.

Although most acetates are artificial products, yet the acetate of potash exists in the sap of some plants. The acetates are, with few exceptions, readily soluble in water, and many of them are easily crystallized: they are a very important class of compounds; some of them, as already noticed, are used in the preparation of acetic acid. The acetate of alumina and the acetate of iron are largely employed by calico-printers; and many of the metallic acetates are used also by them, and by dyers and colour-makers.

ACETIC ACID. This acid, sometimes called also acetous acid, is the sour part of vinegar, and that to which its peculiar and valuable properties are owing. Vinegar, in whatever way made, is, in fact, dilute acetic acid, mixed with colouring matter, and some slight impurities. Acetic acid, as will presently be more particularly mentioned, is a compound of the elements oxygen, hydrogen, and carbon; these bodies, however, cannot be made to combine by direct chemical action, but must be separated from previous combination, either by the agency of fermentation or the action of heat, and they then re-combine to form the acid in question.

The acetic acid exists in the juice of some plants, as will be shown when the chemistry of vegetable substances is treated of; at present it is to be considered as procured,—*first*, by the fermentation of saccharine or sugary matter,—*secondly*, by the action of heat upon wood; the product of the former constituting vinegar, and of the latter, what was formerly called pyroligneous acid, but which is now largely employed, when purified, for most of the purposes to which vinegar is applied.

It is well known that, when certain vegetable juices which contain much sugar, such as that of the grape, are fermented, the first operation, if the heat be not too great, is that of causing the decomposition of the sugar, and the recombination of its elements, so as to form carbonic acid, or fixed air, most of which escapes in the state of gas; and alcohol, or spirit of wine, the greater part of which remains with the fermented juice: this is called the *vinous* fermentation, the product being wine. Now sugar is a compound of three elements, which also form spirit of wine or alcohol,—viz. oxygen, carbon, and hydrogen; and while a portion of the two former unite to yield the carbonic acid, a part of the three combine to form alcohol or spirit of wine.

When the fermentation proceeds farther, as it is apt to do with very weak wines, if exposed to air, and a higher temperature than that at which they were produced, a new arrangement of the oxygen, hydrogen, and carbon, which form the alcohol or spirit, again takes place, and it is converted by this into vinegar, or, in other words, the acetous fermentation is produced. There can be scarcely a doubt that vinegar, as its name implies, was first procured, and most probably by accident, from the passage of the vinous into the acetous fermentation; and, in fact, it is now usually prepared in wine countries, by exposing the wine in casks to the action of the air, at a temperature of about 76° of Fahrenheit's thermometer.

In this country vinegar is procured from an infusion of malt, termed *wort*, which is fermented in the usual way. It is then put into barrels, which are arranged in stoves, with their bungs out, and kept in a temperature of about 84° of Fahrenheit's thermometer. At this heat, which is considerably higher than that required for the vinous fermentation, carbonic acid is produced, which escapes as in the vinous fermentation; while a part of the oxygen, hydrogen, and carbon of the sugar of the malt unite to form vinegar, or acetic acid.

Vinegar thus procured is a well-known reddish brown-coloured liquid; its smell is rather pleasant and refreshing, and its taste is distinctly, but not intensely sour. The strongest malt vinegar is termed by the maker No. 24, and is calculated to contain 5 per cent. of real acetic acid; the manufacturer is allowed to mix with it one-thousandth part of its weight of sulphuric acid (oil of vitriol): vinegar, therefore, is not pure acetic acid, but is a mixture of a small portion of the acid, much water, a little sulphuric acid, spirit of wine, colouring matter, and mucilage.

Vinegar possesses the usual power of acids to redden vegetable blue colours; it combines with the alkalis, earths and metallic oxides to form salts, which are termed acetates, some of which are of considerable importance, being largely used both in the arts and medicine.

Vinegar is purified from the sulphuric acid and colouring matter by distillation, but its smell and taste are then less agreeable: and although it is colourless, it cannot be conveniently or economically employed for the chemical purposes to which purer and stronger acetic acid is applied; not only on account of its weakness, but because the mucilage, which rises with it in distillation, renders the salts formed with it extremely difficult to purify. When vinegar is exposed to a low temperature, it is principally the watery part which freezes; and, although the fluid portion is thus rendered stronger, it is unfit, on account of the presence of the colouring matter and sulphuric acid, for use as acetic acid.

The *second* method of obtaining acetic acid is by heating wood, as the dried branches of trees, in hollow iron cylinders, with a proper arrangement of coolers or condensers and receivers.

The acid thus procured, is called pyroligneous acid, and was at first supposed not to contain the acetic but a peculiar acid, different from all others. It is of a dark brown colour, has a strong burnt acid smell, is very sour to the taste, and acts strongly on vegetable blue colours. It contains a quantity of tar and oily matter; from these it is purified, in a considerable degree, by redistillation, but it is still very impure. It is then to be mixed with chalk or with lime; and when saturated, so as to be converted into acetate of lime, the solution is evaporated to dryness, and then it is what is termed pyrolignite of lime; but it is, in fact, an impure acetate of that earth.

In order to render the acetic acid sufficiently pure, or rather to obtain an acetate fit for that purpose, the pyrolignite of lime is dissolved in water, and there is added to it a sufficient quantity of sulphate of soda (Glauber's salt) also dissolved. Owing to the greater affinity existing between the sulphuric acid contained in the sulphate of soda, and the lime contained in the acetate or pyrolignite, they combine; and the sulphate of lime formed being very sparingly dissolved by the water, it is precipitated in the state of a bulky powder: the soda of the sulphate then unites with the acetic acid of the acetate of lime, and the salt which they form is acetate of soda. This is readily dissolved by the water, and by proper evaporation crystals are obtained, which, by re-dissolving in water and again crystallizing, may be rendered much purer. But if the salt should be still impure, it must be heated pretty strongly in an iron vessel. If the operation be carefully conducted, the impurity only of the acetate of soda is decomposed by the action of the heat; it is then to be again dissolved in water and crystallized, and the crystals, after being once more pretty strongly heated to deprive them of their water, give an acetate of soda fit for use, and yielding pure acetic acid in a mode which we shall now describe.

Reduce seventeen parts of dried acetate of soda to coarse powder, and put it into a glass retort; upon this pour gradually ten parts of sulphuric acid, and subject the mixture to slow distillation in a sand heat. By the mutual action of these substances, the sulphuric acid, on account of the greater affinity existing between it and the soda of the acetate, than between the soda and the acetic acid, combines with the former and releases the latter, which comes over in the form of vapour, and is to be condensed in a glass receiver. In the retort there remains sulphate of soda, which is to be dissolved out and retained for a future operation, with pyrolignite of lime.

The acetic acid thus procured has the following properties: it is fluid and colourless, its smell is exceedingly pungent, and its taste very acrid and sour; if applied to the skin it occasions smarting, and even raises blisters upon it. When heated, the vapour which rises from it takes fire if a lighted taper is exposed to it. At about 45° of Fahr. a portion of this acid becomes solid and shoots into beautiful crystals; these contain no sulphurous acid, even though the product should not have been re-distilled; but a portion of sulphurous acid, formed during distillation, by the decomposition of a part of the sulphuric acid, remains with the uncrystallized acid, from which it may be separated by mixing it with a small quantity of deutoxide of lead (red lead) and re-distillation. The crystals of acetic acid melt at a little below 60° of Fahr.; and the specific gravity of the solution at 60° Fahr., is 1.06296, water being 1. This crystallized acetic acid is sometimes called radical vinegar and glacial acetic acid.

Acetic acid cannot exist except in combination with water, or a base, as the alkali soda, and when in the latter state of combination, and quite dry, it consists of

three	equivalents or	atoms of	oxygen	$8 \times 3 = 24$
three	do.	do.	hydrogen	$1 \times 3 = 3$
four	do.	do	carbon	$6 \times 4 = 24$
			Equivalent or atomic weight	51

The crystals or glacial acetic acid above described consist of

one	equivalent or	atom of	acetic acid	51
one	do.	do.	water	9
			Equivalent or atomic weight	60

Acetic acid may also be obtained by the mere action of heat upon the binacetate of copper, or, as it is sometimes called, though improperly, *distilled verdigris*. The acetate of copper is first to be dried, so as to expel the greater part of the water of crystallization, and then subjected to a pretty strong heat, in an earthen or glass retort, to which a receiver is to be properly adapted. The heat decomposes the salt, and the copper remains in the retort in the state of black or peroxide. The acid when first procured has a greenish tint, owing to the admixture of some peroxide of copper; it must be rendered free from this by redistillation. This acid, though not quite so strong as that procured by the former process, is, however, still more concentrated than that required for general use. The following is a good process for obtaining acetic acid, of sufficient strength for most purposes:—

Put into a glass retort 12 ounces of dry crystals of acetate of soda, and pour upon it 4½ ounces of sulphuric acid, previously mixed with an equal weight of water; when the receiver is adapted, distil, either by the heat of an Argand's lamp, or of a sand heat; about 14 ounces of acetic acid of specific gravity, 1.046 will be obtained, containing nearly 30 per cent. of *real* acetic acid.

The uses to which acetic acid, in the state of vinegar, is applied are too well known to require notice; in the form of pyroligneous acid it is employed to preserve meat, and to impart to it the smoky flavour usually obtained by drying. Pure acetic acid is used in chemical researches, and especially for preparing various acetates. In a less pure state it is employed in the arts for preparing acetate or sugar of lead, acetate of copper or verdigris, and acetate of alumina, largely used by calico printers as a mordant.

ACHÆ'A, one of the ancient great divisions of the Peloponnesus, now the Morea, extending from the river Larissus, near Cape Araxus, along the coast of the Corinthian Bay (Gulf of Lepanto), as far east as the small territory of Sicyon, which separated it from that of Corinth. The Sythas, a petty stream, separated Achæa from Sicyonia. The greatest length, in a straight line between the western and eastern boundaries, is about sixty-five English miles. The breadth of the province varies irregularly from about twelve to twenty miles. Being, for the most part, only a narrow slip between the Arcadian mountains and the sea, the courses of the numerous streams that flow into the Corinthian Gulf are short; and many of them are quite dry in summer.

This province contains many defiles and mountain passes formed by branches of the great Arcadian ridge, which, in some parts, run down to the Corinthian Gulf. The coast is generally low, and has few good ports.

Before this country was occupied by the Achæi, it was called Ægialos, afterwards Ionia, and sometimes Ægialeian Ionia, which probably means no more than 'Ionia on the sea-coast:' it then contained twelve cities or states. The same number of political divisions subsisted under the Achæi in the time of Herodotus, and retained their names under Roman dominion; at present Patræ, now Patras, situated on the coast, about six miles from the entrance of the gulf of Corinth, is the only Achæan town that maintains any importance. The very sites of some of them are, at least, doubtful or unknown. Vostitza is probably the ancient Ægium, where the states of Achæa used to meet. Helice, on the coast, was destroyed by an earthquake, accompanied by an irruption of the sea, B.C. 373. [*Pausanias*, b. 7. chap. 24.] Bura, at the same time, was so violently shaken, that the old statues in the temples were destroyed, and only those persons escaped who happened to be absent from the town. Their descendants were the people who formed one of the members of the subsequent Achæan confederation.

After the Roman conquest of Greece, the term Achæa received an extension in its signification, principally due to the importance which the Achæan league had obtained. The Roman province of Achæa comprehended all Peloponnesus with northern Greece south of Thessaly, perhaps not including Acarnania. But it is exceedingly difficult to fix the precise limits of the Roman provinces of Macedonia and Achæa. Nicopolis, a town which Augustus built near the *northern* entrance of the Ambraciot Gulf (Gulf of Arta) to commemorate his victory at Actium, is included in the province of Achæa, in a passage of Tacitus. (*Annals*, II. 53.) The towns generally preserved their own internal administration, except that the municipal power was put into the hands of the richer citizens.

Achæa was also an early name of the south-eastern portion of Thessaly. [See ACHÆI.]

ACHÆ'I. The Achæi are first mentioned by Homer, as the ruling people of the eastern and south-eastern part of the Peloponnesus. Among the chief cities in their dominions were Argos, Sparta, Mycenæ (the capital of Agamemnon,) Corinth, Sicyon, and the island of Ægina. Among the followers of Achilles to the war of Troy, Achæi are mentioned as well as Hellenes; the latter name, in course of time, prevailed so far as to become the characteristic name of all that people whom we call Greek. From comparing Homer with Strabo and Pausanias, we infer that the Achæi came from Thessaly, and that, at the time of the war of Troy, according to Homer's notion, they were the ruling nation in a large part of the Peloponnesus, and the chief people in the war against Troy. The dominions of Agamemnon comprised the whole country, afterwards called Achæa, which then was probably peopled by Ionians.

The old tradition, as mentioned by Pausanias (vii. 1.), is, that Archander (leader of men) and Architeles (leader of bands) came to Argos from Phthia (otherwise called Phthiotis) and married two daughters of Danaus King of Argos. From this time the name of Achæi prevailed in the Peloponnesus as a *general* name, though Homer also speaks of Argeii and Danai: the last name clearly having a reference to the ancient dynasty or royal family of Argos. The meaning of this story is, that a tradition prevailed that Argos and Mycenæ were, at a period before the war of Troy, occupied by military bands from Phthiotis, and the prevalence of the name Achæi is to be attributed to the warlike character of this people. According to the Odyssey we find the Achæi also in Ithaca.

Eighty years after the war of Troy (B.C. 1104), a fresh band of invaders from the north, the Dorians, drove the Achæi from Laconia and Argolis. Those who did not leave the country became an inferior caste, and entered into the condition of a conquered people; but a large part retreated to the Ægialeian Ionia, and expelled the Ionians. From this date the name of Achæa was given to that province.

The history of the Achæans forms an inconsiderable part of the general history of Greece till about B.C. 251. During the invasion of Greece by the Persians, they took no share in the battles of Marathon, Salamis, and Platæa; nor, during the long war of twenty-seven years, did they take anything more than a kind of forced part in this protracted struggle between Athens and Sparta. At the commencement of this war (B.C. 431), they were, with the exception of Pelléne, neutral; but afterwards favoured the Lacedæmonian interest, in compliance with the general feeling that prevailed in the peninsula. The cause of their taking no part in the general affairs of Greece may probably have been the want of union among the twelve little states; for though they acknowledged a common origin, and had a kind of connexion, they seem not to have had any complete federal system. Yet they probably attained, at an early period, a considerable degree of prosperity and internal good policy, for we find that the Achæans founded several flourishing colonies in Southern Italy; and the political institutions were considered preferable to those of most states, and were often imitated as a model.

During the struggles of the Southern Greeks against the successors of Alexander, the Achæans still wished to remain neutral; but, like all weak spectators of a contest in which they refuse to engage, they became the prey of the victorious party, and suffered under the Macedonians all the evils of anarchy and civil war. Some cities were compelled to receive first the garrisons of Demetrius and Cassander; and afterwards those of Antigonus Gonatas, or to submit to tyrants. There would be little in the whole history of the Achæan states to attract attention, were it not for the federal union which arose out of these discordant elements.

Four of the western states of Achæa, Dyme, Patræ, Tritæa, and Pharæ (Polybius, ii. 41), seeing the difficulties in which Antigonus Gonatas, King of Macedonia, was involved, formed a union for mutual protection, B.C. 281. Five years afterwards Ægium ejected its garrison, and Bura killed its tyrant, which examples moved Iocas, who was then tyrant of the neighbouring town of Ceryneia, to surrender his authority, and save his life. These three towns joined the new league. In B.C. 251, Aratus having delivered Sicyon, which was not an Achæan town, brought it over to the confederacy, of which he contrived to get himself elected head. In 243, having succeeded in driving the Macedonian garrison out of the strong hold of Corinth, which is the key of Southern Greece, this town also joined the league. Megara, Epidaurus, and Trœzen, followed soon after. Our object is not to write the history of the league, but to show how it gradually rose to importance; we, therefore, refer to the article ARATUS for the events belonging to his period. In the year B.C. 208, five years after the death of Aratus, Philopœmen was elected general of the confederacy, to which he gave a new life by his activity and wisdom (see PHILOPŒMEN). As the Romans had now humbled Philip II. of Macedonia (B.C. 197), and reduced him to the rank of a dependent king, it was their policy to weaken the power of the confederation, and this was easily effected by the Roman and anti-Roman parties, which had been for some time growing up in the Greek cities. In 191, however, Sparta became a member of the Achæan league, and the design of its leaders was to include all the Peloponnesus within its limits. After the death of Philopœmen (B.C. 183) the Roman party grew still stronger under the influence of Callicrates, and the league remained, in appearance at least, on the side of the Romans in their final struggle with Perseus, king of Macedonia, which ended in the defeat and death of the monarch (B.C. 168). The influence of Callicrates was now almost supreme, and, so far from opposing, he urged the Romans to demand 1000 of the noblest Achæans to be sent to Rome to answer for their conduct in the late war. Callicrates and his party had named more than 1000, of whose guilt, however, no proof was adduced; his only object was to humble the party of his opponent Lycortas. Among the accused who were sent to Rome, and there detained for seventeen years, was the historian Polybius, the son of Lycortas, and the strongest support of his father's party.

The last war of the league was with Sparta, which was brought about (150 B.C.) through the influence of Critolaus, one of those who had been detained at Rome. This, which the Romans chose to consider as a kind of attack on themselves, joined to the contumacious treatment of the Roman commissioners at Corinth, which will be presently mentioned, induced the Republic to send L. Mummius to chastise the Achæans; and a fitter man for the purpose could not have been found. The treatment of the Roman commissioners did not tend to soften the ferocity of their barbarian opponent. The Achæan general Diæus met Mummius on the isthmus of Corinth, and fell an easy prey to the Roman general, who, after the battle, burned Corinth to the ground (B.C. 146). Mummius and ten other senators then changed Greece into the Roman province of Achæa, leaving, however, to certain cities, such as Athens, Delphi, &c., the rank of free towns. Corinth afterwards received a Roman colony.

To those who study the history of civil polity, it is a matter of some interest to trace the formation of federative systems, or those by which a number of states unite for certain general purposes, while each maintains all its sovereignty except that portion which is surrendered to the sovereignty of the united states. The object of such associations is two-fold—to secure peace and a ready intercourse between all the states, and all the members of them; and, secondly, to facilitate all transactions with foreign states, by means of the sovereign power given to the united body. Defence against foreign aggression is one of the main objects of such a union; while foreign conquest is, strictly speaking, incompatible with it.

The history of the Grecian states presents us with many examples of federal unions of various kinds, but none is more familiar to the ear than the Achæan, about which, however, our information is not complete, nor yet always precise. We shall endeavour to state what is known in as brief a way as possible.

Each state had an equal political rank, retained its internal regulations, and its coins, weights, and measures, as we know from extant specimens, though the general government also had its coins, weights, and measures, which were uniform. We are speaking of the league as it existed in its completest state. The ordinary general assemblies were held twice a year at Ægium (afterwards at Corinth), and they deliberated for three days. Extraordinary assemblies might meet at other places, as, for instance, at Sicyon. At the Spring meeting, about the time of the vernal equinox, the public functionaries were chosen; the *stratégos*, or head of the confederation, was there chosen, with the *hipparchus* or master of the horse, who held the next rank, and ten functionaries called *demiurgi*. This was the time of election, in the time of Aratus at least. In the earlier times of the league they had two strategi and a secretary, as the Romans had two consuls; but, in B.C. 256, after twenty-five years' experience, it was found that one head was better than two. The strategos appears to have been elected for a single year, and not to have been re-eligible till he had been one year out of office. We find that Aratus filled the office of strategos seventeen times in thirty-three years, and Philopœmen was elected eight times in twenty-four years; Marcus of Ceryneia was the first sole strategos. If the strategos died in office, his predecessor assumed the functions till the legal meeting of the congress. The functions of the ten demiurgi we are not able to state satisfactorily; they probably possessed the legal right to summon and preside in the ordinary meetings; and certainly they must have prepared the business which was to be so summarily despatched in three days. It seems that they had the power, within some limits, of referring matters to the public body or not, according to a majority of votes in their own body: they were, in fact, a committee, having a kind of initiatory (Liv. xxxii. 22). It may be asked how was the general council composed, particularly after the League comprised within itself so many states? Did the states send deputies? Had they, in fact, a representative government? It is difficult to answer this question, though we are inclined to think there was no strict system of representation. The short time for discussion, the two yearly meetings, the general character of Greek democracy, as well as most passages in which the congress is spoken of, lead us to infer that this deliberative body consisted of every citizen of the confederate states who chose to attend. That this, however, could only be the case with the wealthier class, and that the poor could not attend to such business so far from home, must be self-evident. It is also certain that, on extraordinary occasions, a much larger number of men assembled than was usual when things were going on in a more regular course. We read of one special instance (Polyb. xxxvii. 4) when the Roman commissioners were kicked out of the congress, then sitting at Corinth, with scorn (B.C. 147); and Polybius adds, by way of explanation, 'for there was assembled a number of the working class, and of those who followed mechanical occupations, greater than on any former occasion.' As Corinth, however, was one of the greatest manufacturing towns of Greece, and the working class occupied a higher station there than those in most other places, it is possible that the regular meeting was disturbed by a body of intruders, as we sometimes have seen at our own elections. We are, however, inclined to adopt the opinion of there being no representative system in the Achæan congress. Another passage of Polybius tells us that Eumenes offered the congress, then sitting at Megalopolis, a large sum of money, that they might, with the interest of it, pay the expenses of those who attended the congress: this would imply that the number was in *some way* limited, but *how* we do not undertake to say. The offer of Eumenes was rejected. Other matters relating to the Achæan league, though curious to the scholar, are too little fixed to be admissible here.—[See *Polybius*, Book ii. 4, &c. (Hampton's Translation); *Strabo*; *Pausanias*, Book vii.; *Schlosser's Universal History*; *Hermann, Lehrbuch der Griechischen Staatsalterthümer*.]

ACHARD (FRANCOIS-CHARLES), a chemist and experimental philosopher, supposed to have been of French extraction, was born at Berlin in 1753 or 1754, and died in 1821. He was the author of various works, written in the German language, on experimental physics, chemistry, and agriculture; and he was long an active contributor to different scientific journals, particularly the Memoirs of the Academy of Berlin. In 1780 he published, at Berlin, a work entitled *Chymisch-Physische Schriften*, which contains a great number of experiments on the subject of the adhesion of different bodies to each other. Tables containing the results of these experiments, which seem to have been conducted with great care, may be seen in the *Encyclopédie Methodique Chimie*, tom. 1, p. 469.

Achard is, however, chiefly known for his proposal to extract sugar from beet-root. Another Prussian chemist, Margraff, had discovered the existence of a certain portion of sugar in this root, as early as 1747. He communicated his discovery to the Scientific Society at Berlin; but he himself thought it of little practical importance, as he declared he could not produce sugar under 100 francs the pound. Achard, who in this particular appears to have been somewhat of a visionary, on the contrary, described the beet-root as 'one of the most bountiful gifts which the divine munificence had awarded to man upon the earth.' He affirmed that not only sugar could be produced from beet-root, but tobacco, molasses, coffee, rum, arrack, vinegar, and beer. 'The Institute of Paris,' in 1800, gave Achard the honour of a vote of thanks; but after a series of careful experiments they reported that the results were so unsatisfactory, that it would be unwise to establish any manufacture of sugar from beet. But Napoleon, in 1812, succeeded in forming an imperial manufactory of sugar at Rambouillet, when his decrees had deprived France of the produce of the West Indies. The sugar made at home was sold at a great price; and, consequently, after the peace, when foreign sugar was once more introduced, its cheapness put an end to the beet-root establishments. The government of France, however, chose to levy high duties upon the sugars of English colonies to protect those of Martinique, Guadaloupe, and Bourbon; and the tax upon English colonial sugar, being now 95 francs the 100 kilogrammes, or about half a franc per pound, amounts to a prohibition. The beet-root manufacture, therefore, was revived, and is now flourishing, for the sugar so produced pays no duty whatever. In plain words, the manufacture is flourishing, because the people of France are compelled to buy dear sugar instead of cheap. Sugar in that country is only consumed by the wealthy. The average yearly consumption of sugar in France is 4 lbs. for each individual of the population; in the United Kingdom it is 20 lbs. The expectations which Achard formed of the blessings which the beet-root was to produce have not therefore been realized. His plan, like all other plans for raising an article at home which could be obtained better and cheaper by exchange, has only had the effect of keeping the great body of consumers ill supplied, that a few might thrive by a monopoly.

ACHELO'US (now ASPRO POTAMO, or WHITE RIVER) is the largest stream in Greece, properly so called, and was considered navigable in ancient times as far as Stratos, the ruins of which town, if we trust Pouqueville, are about a mile and a half south of a village now called Lepénu. The Achelous rises in the lofty mountain range of Pindus, which is the back-bone of northern Greece, and, after flowing through a very uneven country, enters the level land of Acarnania. Here it discharges itself into the sea; in ancient times having near its outlet the town of Œniadæ. Its general course is from north to south, and its length may be from 120 to 140 miles. In the time of Thucydides (B.C. 431) the lower waters of the Achelous were considered as belonging to Acarnania, but at a later period this river formed a boundary between Acarnania and Ætolia. At the time when the present king of Belgium, Leopold I., had the offer of the sovereignty of Greece from the three great powers, this river was intended to form the north-western boundary of the new state, as far as a point in its course from which it struck eastward through the lakes of Ætolia; but the limits of Greece, it is now understood, will be removed farther north, and determined by a line running from the Gulf of Arta to that of Volo.

The Achelous, flowing from a high mountain range, and in the winter season being loaded with water, carries down an immense quantity of earthy particles, which have formed a number of sand-banks and small islands at its mouth, called in ancient times the Echinades: this phenomenon was remarked by Herodotus one of the earliest observers of geological facts whose writings have come down to us, who compares the increase of the Egyptian Delta, from the quantity of alluvium brought down by the Nile, with the effects produced by the deposits of the Achelous. In the time of Thucydides these islands were increasing so fast, that he predicts (ii. 102) all of them will be shortly joined to the main land; some, he says, were already attached to it. There is still, however, a great number of small islands near the mouth of the Aspro Potamo, but whether some of them have been formed since the time when Thucydides wrote (which is above 2000 years ago), or are the same islands, which the Athenian historian tells us were uninhabited in his time, we do not know. Nothing but a much more minute survey of these islands, and the lower course of the Achelous, together with the present workings of the river, will enable us to come to any probable conclusion as to the changes that have taken place about its mouth. It was a tradition extant in the time of Thucydides that there were no islands at the mouth of the river about a century before the war of Troy; yet, in Homer, we find the Echinades mentioned as sending troops to Troy, while the Echinades of Thucydides' time were uninhabited. All this will tend to prove that the term Echinades was not always used exactly in the same sense as to the number of islands which it included, and also that very great changes had taken place near the mouth of this river. Were the localities examined by some competent person, it might lead to important results as to the progress of deltas within given periods and under certain conditions.

A'CHERON, a small stream of Elis, that runs into the Alpheus; better known for the importance assigned to it in the Greek mythology, than for anything else. In the neighbourhood of this river, says Strabo, they honour Ceres, Proserpine, and Hades. The Acheron was one of the rivers of the realms below, over which the dead had to pass; sometimes the lake is mentioned as the stream which is to be crossed. There was also a river called Acheron, in Thesprotis, a part of Epirus: this stream rises in the mountain range of Pindus, forms, in its course, a considerable lake, called Acherusia, and finally enters the sea, forming a bay, called, by Strabo, Sweet-port (Glykys Limen), and now Porto Phanari.

There was a third river called Acheron, in Southern Italy. The name Acherusia was given to the Lucrine, or else to the lake of Avernus, in Italy; and the hot springs in the neighbourhood were supposed to be near Pyrophlegethon, or the river of fire, in the infernal regions.

It is curious to observe how widely the name of Acheron was diffused by the people of Greek stock, and was always connected with the supposed character of the world below. The origin of this appears to have been some local peculiarities, which fear, proceeding from ignorance in remote ages, turned into objects of superstitious veneration. Even on the coasts of the Euxine, near Heraclea (Erekli), we find a peninsula called Acherusia, where Hercules is said to have descended to bring up the dog Cerberus. The Greek historian, Xenophon, who gravely reports this story, adds, what is more important, that there is there a deep chasm or ravine, extending several hundred yards in length.

ACHILLEA, a genus of plants, consisting of sixty or seventy species, found exclusively in the colder climates of the northern hemisphere. They are all herbaceous, perennial weeds, of little importance, except to botanists, and are only seen in cultivation in the collections of the curious.

ACHI'LLES. One of the most celebrated characters of the mythic age of Greece; a distinction due rather to his having been selected by Homer as the hero of the Iliad, than to the number or wonderful nature of the exploits ascribed to him. He belongs to that intermediate period between truth and fiction, during which it is generally hard to say how much is real—how much imaginary. In the circumstances of his life, however, as they are told by Homer, there is scarcely anything impossible, or even improbable, allowing for a reasonable quantity of poetical embellishment. Beyond Homer's account, however, everything is fabulous; and as poets seem to have regarded these mythic stories as fair ground on which to exercise their own taste and invention, careless of making their additions consistent with what others had said before, it is not wonderful that the accounts of this prince, as of many others, abound in contradictions which it would be fruitless to try to reconcile.

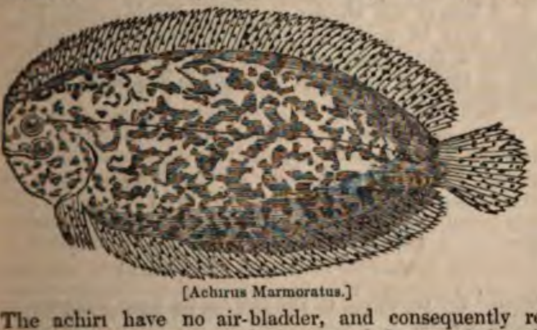
The story of Achilles, as we find it in Homer, is soon told. He was the son of Peleus, king of Phthia, (see Achæi,) and the adjoining parts of Thessaly, and of Thetis, a sea goddess, daughter of Nereus. He was educated by Phœnix, a refugee, at his father's court. Fate had decreed that, if he fell before Troy, he should gain everlasting renown; if he returned home he should enjoy a long but inglorious life. He chose the former alternative, and joined the Grecian army, in which he was pre-eminent in valour, strength, swiftness, and beauty. During the first nine years of the war we have no minute detail of his actions in the tenth a quarrel broke out between him and the general-in-chief, Agamemnon, which led him to withdraw entirely from the contest. In consequence the Trojans, who before scarcely ventured without their walls, now waged battle in the plain with various issue, till they reduced the Greeks to extreme distress. The Greek council of war now sent its most influential members to soothe the anger of Achilles, and to induce him to return to arms, but without effect. He allowed his friend and companion, Patroclus, however, clothed in the celestial arms which Hephæstus (Vulcan) gave his father, Peleus, to lead the Myrmidons, his followers, out to battle. Patroclus was slain, and stripped of these arms by Hector. Rage and grief induced Achilles now to return to battle. Thetis procured from Hephæstus a fresh suit of armour for her son, who, at the close of a day of slaughter, killed Hector, and dragged him at his chariot wheels to the camp (not thrice round the city, as in later authors). Here ends the history of Achilles, so far as it is derived from Homer, except that we may infer, from a passage in the last book of the Odyssey, that he was slain in battle under the walls of Troy. But the genuineness of the last book of the Odyssey has been disputed both by some excellent ancient and modern critics, and, as we think, on very good grounds.

By later authors a variety of fable is mixed up with this simple narrative. Thetis is said to have dipped him, while an infant, in the Styx, which rendered him invulnerable except in the heel, by which she held him, and he was killed at last by a wound in the heel. The centaur Chiron is made his tutor, instead of Phœnix, and feeds him upon the marrow of lions and other wild beasts, to improve his strength and courage. From this singular instructor he learned music and a number of sciences, even before the age of nine years, at which Thetis, anxious to prevent his going to Troy, removed him, disguised as a girl, to the court of Lycomedes, king of the island Scyros. Here he became the father of Neoptolemus, or Pyrrhus, by the king's daughter, Deidamia, rather precociously; for he had not been a year on the island, when Ulysses was sent by the confederate Greeks to seek him, in consequence of an oracle, which declared that Troy could not be taken without the help of Achilles. Ulysses arrived at the island, discovered him among the females of Lycomedes' household, and carried him away to join the army. He was betrothed to Iphigenia, daughter of Agamemnon. The manner of his death is variously told. Some make him fall in battle; others say that he was treacherously slain in a temple, on the occasion of his nuptials with Polyxena, daughter of Priam; but it is generally agreed that he was killed by Paris, Apollo aiding him, and directing his arrow. He was entombed on the promontory of Sigæum, and a mighty barrow raised over his remains, which still rivets the attention of travellers; though it must always remain doubtful to whose memory this mound of earth was really raised. Here Alexander of Macedon celebrated splendid games in honour of the hero whom he affected to emulate.

The most valuable historical facts relative to Achilles are contained in the following passage of *Homer's Iliad*, book II. 681, &c., where he is giving a list of the warriors who went to Troy:—'I will now tell of those who inhabited Pelasgic Argos, with Alus, Alope, and Trechis; and those who dwelt in Phthia and Hellas, famed for beautiful women, and were called Myrmidons, and *Hellenes* and *Achæi;* the commander of their fifty ships was Achilles.' From this we learn that there was a people in Thessaly called Achæi, as well as a people in the Peloponnesus; and we see also that the name of Hellenes, afterwards the generic name of the Greek nations, originated, as far back as we can trace it, in the basin of Thessaly.

ACHI'LLES TA'TIUS, a Greek astronomer, who lived, probably, in the first half of the fourth century of our æra, and wrote a treatise on the sphere. There is still extant a fragment of Achilles Tatius, entitled *An Introduction to the Phænomena of Aratus:* it may be seen in the Uranologion of Petavius. Suidas, the lexicographer, confounds this Achilles Tatius with another of the same name, called by him Achilles Statius, who lived later, and wrote a Greek romance, *The History of Leucippe and Clitophon*. This Achilles was a native of Alexandria in Egypt, and though it is difficult to fix his era with any precision, we may assume him to be later than Heliodorus, whose romance served as a kind of model to all the subsequent Greek writers of that class, as well as to Achilles. Probably, Achilles Tatius wrote near the close of the fifth century. His romance is in eight books, and is preferred by some of the earlier critics to that of Heliodorus, which latter, however, appears to us one of the most insufferably tedious stories that ever was written. Later critics give the preference to Heliodorus. Those who have not the opportunity of reading the Greek romance writers, may form some idea of their subjects, and the mode of treating them, by dipping into some of the older romances of modern times, such as *Apollonius, King of Tyre*, on which the tragedy of *Pericles*, which, bad as it is, has been supposed to have had some touches from Shakspeare, is founded. The Greek romance writers give us no vivid picture of the times in which they lived, but a distorted image of forms of society far anterior to their own age, without being able to infuse into them the spirit of historic truth. [*Schoell, Hist. Greek Litt.*—See an article on the Greek Romances in the *Foreign Quarterly Review*, No. 9.]

ACHI'RI, in Ichthyology, a genus of flat-fish, belonging to the order Malacopterygii, and family Subbranchia, of Cuvier. In external form these animals resemble the common sole: like the pleuronectes, in general, they have the body and tail very much compressed, and the eyes both on the same side of the head; but they are easily distinguished from all other genera of flat-fish by the total want of pectoral fins. These organs, it is true, are very much reduced in all the pleuronectes; because, being placed in a different situation from the fins of ordinary fishes, they no longer perform the same functions in relation to the medium in which they move, but the stability of the animal's equilibrium is preserved, and its movements of locomotion performed, by the dorsal and caudal fins, instead of by the pectoral and ventral. Hence it is that the former fins always acquire such an enormous development in flat-fish; being generally continued in an uninterrupted line from the head to the tail, and not unfrequently surrounding the whole body.



[Achirus Marmoratus.]

The achiri have no air-bladder, and consequently remain, for the most part, at the bottom of the sea; being, in fact, ungifted with the faculty of increasing or diminishing their specific gravity, which the possession of this important organ bestows upon ordinary fishes. Their power of locomotion in other directions is, however, considerable; and, notwithstanding the disadvantages of their form, and the oblique direction in which this necessarily compels them to move, their motions are frequently very rapid. Their habits, as far as at present known, are similar to those of the other pleuronectes. They are found in the warmer regions both of the East and West Indies, but not in deep water, or in situations far removed from land; they abound along the shores, and furnish a plentiful and wholesome food to the inhabitants.

Lacepede and some other naturalists have divided the achiri into two subgenera; the first of which is distinguished by having the eyes on the right side of the head, and the caudal fin distinct from the dorsal and anal; the second, by having the eyes placed on the left side, and the dorsal and anal fins joined to the caudal, so as to form but a single uninterrupted line of fin around the entire body, the head alone excepted.

Various species of achiri have been enumerated by zoologists, the most remarkable of which appears to be the *Achirus Marmoratus* of Lacepede. This species has the caudal fin distinct from the anal and dorsal, all of which are of a pale bluish-white colour, sprinkled with innumerable small black spots; the body is covered with very diminutive scales, and the flesh is of a delicate flavour, and highly esteemed: it inhabits the coasts of the Isle of France. But the most remarkable fact relating to this species is reported by Commerson, who informs us that there is a small pore at the base of each of the rays of the fins, from which issues, upon pressure, a milky fluid of the consistence of olive oil. We are entirely ignorant of the purposes which this fluid serves in the economy of the animal; undoubtedly, it has its uses, and probably is under the control of the creature's volition, and may assist it, in some manner, either in capturing its prey, or in eluding the attacks of its enemies. The *Achirus Pavonicus* is distinguished by the beauty of the spots, which, like the eyes on the peacock's tail, cover its body; and the *Fasciculatus* and *Bilineatus* are easily recognized by the characters from which they respectively derive their names. The former is found on all the coasts of America and the West Indian isles: the latter inhabits the shores of China, and feeds upon small crustacea and mollusca. It has a long intestinal canal, with numerous reduplications; its jaws are armed with short obtuse teeth; and each of its nostrils has two distinct orifices. Various other species are found in the Atlantic and Indian oceans: they are enumerated in a note, vol. ii. p. 343, of the second edition of the *Règne Animal*, and described at length by Lacepede, and other writers upon ichthyology. To these sources we must refer such of our readers as are desirous of further information regarding the external forms, and specific differences of the achires. All that is known of their habits and economy has been brought together in the present article.

ACHMIN, or ACKMIN, a town in Middle Egypt, N. lat. 26° 38′, on the right bank of the Nile, with which it is connected by an ancient canal. Achmin contains above 3000 inhabitants, who manufacture some coarse cotton cloth; 2000 are Catholic Copts, who have a large church. This town is the Chemmis of Herodotus and other Greek writers, the Arabic name, Achmin, being formed by prefixing the letter A, which we find to be the case in many other names. Herodotus mentions a large temple here with colossal statues. At present there are the ruins of two temples to be seen at Achmin, and on an architrave, at this place, a Greek inscription has been discovered, which contains a dedication to the god Pan; thus confirming the opinion that the Panopolis of the later writers was the old Chemmis of Herodotus, a name which endures to the present day. The hills in the neighbourhood of this town are full of excavations, which perhaps originally served to receive the mummies of Chemmis, and afterwards to shelter the Christians during the cruel persecutions of Diocletian. [See *Egypt, Society—Ritter, Afric.*]

ACHRAS, a genus of tropical plants belonging to the natural order Sapoteæ. The name strictly belongs to the wild pear, and seems to have the same root as Acacia, Acanthus, and other words indicating something prickly. Linnæus, with a capriciousness too usual with him, gave it to this West Indian genus, which has nothing whatever in common with the pear.

GENERIC CHARACTER.

Calyx divided into six parts.
Corolla monopetalous, divided into six lobes.
Stamens twelve; of which six are sterile, and six fertile.
Ovarium with from six to twelve cells.

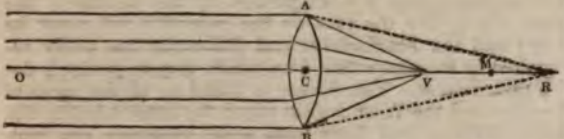
Fruit resembling an apple, with from one to twelve seeds, contained in hard bony nuts, which have a shining coat, and a long hard scar over the whole of their inner angle.

The genus contains only one species, which yields a copious milky fluid when wounded. Its leaves are entire, leathery, undivided, shining, of a lanceolate form, without stipulæ. The flowers are large, white, bell-shaped, and grow singly from the axillæ of the leaves. This is called, in the West Indies, the *Sapodilla Plum*, and *Nispero* by the inhabitants of New Spain. The fruit in size and shape resembles a bergamot pear: like the medlar, it is only eaten in a state of decay; before that period it is austere and uneatable, but in the proper state it is so rich and sweet, as by some to be considered only inferior to the orange. For other presumed species of Achras, see LUCUMA.

ACHROMA'TIC. An optical term, derived from the Greek, and signifying 'without colour.' It is used in speaking of telescopes and other combinations of glasses, to designate those which are so contrived that the light which is broken into various rays of different colours by one glass, is re-collected, or nearly so, by another; so that the image does not present those coloured fringes round its edge, which are always observable in bad telescopes.

It is well known that light is not a simple body, but is divided or decomposed into various colours by passing it through glass, or any other transparent substance, the sides of which are not parallel to one another. [See Society's Optics, ch. viii. ix.; also the articles PRISM, SPECTRUM.] That is, whenever an object is seen through a common lens, there are, in fact, several images which arise from rays of different colours being collected at different points, as follows:—

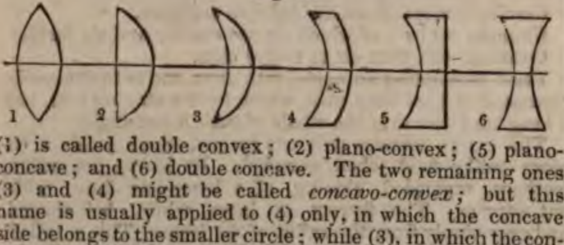
Fig. 1.



A B is the section of a double convex lens, which may be made by the revolution of the figure A B about the axis O R. We suppose rays to fall upon it coming from a point in the axis O R so distant from the lens, that they may be considered as parallel. The light in passing through the lens is refracted; that is, the rays of each separate colour are directed nearly to the same point, the violet rays being brought nearest to the glass at V, and the red rays being farthest from it at R. Between V and R will be scattered a succession of images of those colours which lie between the violet and red. In this we observe two distinct effects. First, the general *refraction* of the rays, by which they are bent so as nearly to meet in one point. This is usually measured by the *mean* ray, or the colour which falls in the middle between V and R; and of two lenses of the same form, but of different substances, that is said to have the greatest refraction which brings the mean image M nearest to C, the centre of the lens. Secondly, the separation of the images V R, which bears a certain proportion to C M, is called the *dispersive power* of the medium. Thus, if two lenses of the same form, but different substances, have V R the same in both, it does not follow that the dispersive powers of the two are the same. If C M should happen to be in the first substance double of what it is in the second, V R being the same in both, the dispersive power of the first would be only half that of the second. The dispersive power is found thus:—Divide the difference between the *refractive indices* (see REFRACTION) for red and violet rays, by the refractive index of the mean ray diminished by unity. To make A B achromatic, we must find another substance, differing from the substance of A B, so that some lens of it, placed before A B, will collect the light scattered by A B, without causing the rays again to become parallel to one another. To do this we first lay down the following rules for computing the distance of any one image from the centre of the lens, or what is called the *focal* distance of that image. These may be seen more at length in the art. LENS.

I. There are six species of lenses, made by the revolutions of the following figures about the axis:—

Fig. 2.



(1) is called double convex; (2) plano-convex; (5) plano-concave; and (6) double concave. The two remaining ones (3) and (4) might be called *concavo-convex;* but this name is usually applied to (4) only, in which the concave side belongs to the smaller circle; while (3), in which the concave side belongs to the larger circle, is called the *meniscus.*

II. Of these, in (1), (2), and (3), parallel rays are made to converge as in *fig.* 1,—that is, they are actually collected on the other side of the lens: in (4), (5), and (6), on the contrary, they are made to *diverge,*—that is, they are not collected at all, but proceed as if they came from some point on the same side of the lens as that on which they fell; the general rule is, that those with sharp edges make parallel rays converge, while those with flat edges make them diverge. It is usual to give the name of *convex* to the sharp-edged, and of *concave* to the flat-edged lenses.

III. To find the focus, that is, either the point at which the rays really do converge, or that from which they appear to diverge, divide the product of the radii of the surfaces by their sum, when both sides are of the same name (that is, for the double convex and double concave); by their difference, when the sides are of different names (that is, for the meniscus or concavo-convex), and divide the quotient by the refractive index of the substance, diminished by unity. The result is the distance of the focus from the centre of the lens. When one side is plane (as in the plano-concave and plano-convex), divide the radius of the other side by the refractive index diminished by unity. For common glass the refractive index is nearly $\frac{3}{2}$, or, according to Dr. Brewster, varies from 1·5 to 1·54 for *plate* glass, from 1·525 to 1·563 for *crown* glass, and from 1·576 to 1·642 for *flint* glass. This, diminished by unity, is nearly $\frac{1}{2}$ in all cases, and dividing by $\frac{1}{2}$ is the same as multiplying by 2. Hence, for a double convex lens, the radii of whose surfaces are 6 and 8 inches, the product of 6 and 8 divided by the sum of 6 and 8 is 3 inches, and $\frac{3}{7}$ of an inch nearly; and twice this quantity gives 6 inches and $\frac{6}{7}$, or 4 inches nearly, for the *focal distance* of the lens.

IV. When two lenses are placed close together, one of which has sharp edges and the other flat, and parallel rays fall on them, the focus of the two together falls on the side of the stronger, or of that which has the *least* focal distance. When both edges are sharp or both flat, the focus of the two falls on the same side as that of either lens.

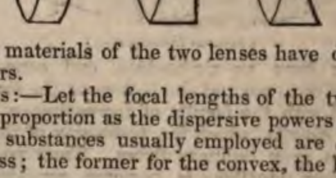
V. The focal distance of such a compound lens is found by dividing the product of the single focal distances by the sum, when both are sharp or both flat; or by the difference when one is sharp, and the other flat on the edge.

To make one lens achromatic by the addition of another, involves a process of reasoning which we shall omit, and merely give the result:—

1. No such single additional lens can give entire achromatism or absence of colour; all it can do is to bring some two images of different colours into the same place. If we thus choose to bring the two extreme images together, the remaining ones, though not actually brought into the same place with the two first mentioned, will yet come so near them, that, for practical purposes, the object in view will be attained.

2. A lens of the convex species, a double convex for instance, may be made very nearly achromatic, by applying to it one of the concave species, which fits one side of it exactly, so that the section of the double lens shall be one of the following—

Fig. 3.



provided the materials of the two lenses have different dispersive powers.

The rule is:—Let the focal lengths of the two lenses be in the same proportion as the dispersive powers of their material. The substances usually employed are *crown* glass and *flint* glass; the former for the convex, the latter for the concave lens.

The dispersive power of flint glass is nearly double that of crown class; while the refractive powers of the two are nearly the same for the *mean* image. Suppose we have a convex lens of plate glass, of 10 feet focal distance for the mean image, which we wish to achromatize by a lens of flint glass, the refractive indices being as follows—

	Red.	Mean.	Violet.
Crown . . .	1·526	1·533	1·547
Flint	1·623	1·637	1 666

The dispersive power of the crown glass, or, as before explained, the quotient of ·021, the difference between the red and violet refractive indices, divided by ·533, is ·0394. That of the flint glass, or ·043 divided by ·637, is ·0675. Hence, 10 is to the focal distance of the lens required as ·0394 to ·0675, or as 394 to 675, which gives 17 feet 2 inches nearly, so that the focal length of the whole lens, found as in rule (5), is about 24 feet.

If the focal length of the concave lens be too short for the purpose, the defect may be remedied by separating the lenses a little, instead of putting them close together.

By the preceding account, some idea may be formed of the manner in which chromatic aberration is destroyed in the object-glass of a telescope. Newton, who imagined that the dispersive and refractive powers were always in the same proportion, thought it would be impossible to construct an achromatic glass. This was first done, as far as we know, about the year 1730 by Mr. Hall, a gentleman of Essex; but he concealed his discovery. Dollond (see his life) was the first who publicly made achromatic telescopes. Huyghens had accidentally constructed an achromatic *eye-glass*, in the course of an experiment for a different purpose. On this part of the subject consult the article TELESCOPE; we also refer the mathematical reader to Mr. Coddington's Optics, and to a paper by Professor Airy, on achromatic eye-pieces, published in vol. ii. of the *Cambridge Phil. Trans.*

ACIDS. The acids are a numerous and important class of chemical bodies. As the word acid is, in common language, almost synonymous with *sour*, it might be supposed that the taste of a substance would determine whether it was included among the acids. The term has, however, been so much extended by chemists beyond its original meaning, that some bodies, which are nearly or quite devoid of sourness, are considered as acids because they agree with them in some other qualities. The acids are generally sour; usually, but not universally, they have great affinity for water, and are readily soluble in it: they redden most vegetable blue colours, and combine readily with alkalis and earths, and act upon and unite with most metals, or their oxides, with great facility. These are the properties of the greater number of acids; but the last only—namely, great powers of combination—belongs to them all. Many acids are entirely natural products, some both natural and artificial, while others are altogether the result of chemical agency. They are derived from various sources, and, except in the few particulars above-named, they vary greatly in their properties. Thus, under common circumstances of temperature and pressure, some are gaseous in form, as the carbonic acid; others are fluid, as the nitrous, or solid, as the boracic acid; some require water or a base to retain their elements in combination, which is the case with the nitric acid, while others, as the sulphuric, may exist independently of either. Most acids are colourless, but the chromic is red; some are inodorous, as the sulphuric; others pungent, like the muriatic acid: there are acids which are comparatively fixed in the fire, the phosphoric for example; others are volatilized by a more moderate heat, which is the case with the sulphuric acid; whilst those which are pungent to the smell, like the muriatic acid, are, to a certain extent, volatile at all temperatures.

No simple or elementary substance has the properties of an acid, and consequently all acids are compounds of two or more of them. In almost every case one of these elements is either oxygen or hydrogen; those acids which contain the former are sometimes termed *oxacids*, and those into the composition of which hydrogen enters are called *hydracids*. Oxygen in some instances gives rise to different acids, by combining with the same element in various proportions; thus, oxygen and azote form three acids, which is also the case with oxygen and sulphur, and oxygen and phosphorus; but hydrogen does not in any case combine with the same element to form more than one acid. The oxacids greatly exceed the hydracids in number.

Acids occur in all the kingdoms of nature; the phosphoric acid existing in bone is of animal origin; the citric and the oxalic acid are products of vegetation; while the chromic and the arsenic acid enter into the composition of certain minerals. In many instances, however, acids are not exclusively derived from one source, but are sometimes produced by them all, and may be also artificially formed. This is the case with the phosphoric acid, which occurs in animals, plants, and minerals, and is formed whenever phosphorus is burnt the citric acid is produced only by the process of vegetation; but the oxalic acid, also found in plants, may be obtained by chemical agency. The carbonic and the sulphuric acid are very common in mineral bodies, and may also be artificially produced; the former is also one of the results of respiration, combustion, and of animal and vegetable decomposition; and both the carbonic and sulphuric acid may be obtained by combining their bases with oxygen. The chromic and the arsenic acid are found only in mineral bodies, but they may be formed by chemical agency; and, indeed, except many of the vegetable acids, there are but few which cannot be so prepared.

Soon after Dr. Priestley's celebrated and important discovery of what he called *dephlogisticated air*, in 1774, it was found that several substances, such as sulphur and phosphorus, were converted into acids by combining with this elementary gas. On this account it was assumed, hastily and incorrectly, that all acids contained dephlogisticated air, and derived their acidity from it; on this account the name *oxygen* was given to it, signifying *acid-making*, and it was regarded as the universal acidifying principle; not, indeed, that it always formed an acid when combined with a body, but that no acid existed without it. It has, however, since been found that there are acids, the muriatic acid for example, which contain no oxygen: and, further, it has also been proved, by the brilliant discoveries of Sir H. Davy, that oxygen, by combining with certain elementary bodies, converts them into *alkalis;* a class of substances possessing properties diametrically opposite to those of the acids.

Although, as already mentioned, oxygen or hydrogen is present in almost every acid, yet on account of the very different classes of bodies of which they frequently form a part, they are not regarded as acidifying principles: acidity, like form, colour, and other less obvious properties, is to be considered as the result of chemical action and combination, and not as derived from the agency of any peculiar principles.

The means adopted for preparing the acids, whether from the natural compounds which contain them, or by the direct combination of their component parts, are almost as various as the acids themselves. For an account of the processes employed in obtaining them, and of the numerous and important purposes to which the acids are applied in medicine, science, and the arts, or for domestic uses, we refer the reader to each particular acid.

It may be here proper to notice the method adopted by the framers of the French nomenclature, in giving names to different acids. It has been already mentioned, that oxygen was supposed to be the acidifying principle, and it was found that, by combining in different proportions with the same substance, it formed acids of very different properties; but it was not then known that oxygen combined with any one body to form more than two acids. It was, however, proved to unite with sulphur in two different proportions; and in this, and similar cases, the name of the acid which contained least oxygen was made to end in *ous*, and that which contained more in *ic;* thus sulphur*ous* acid contains less oxygen than sulphur*ic* acid.

Cases have, however, occurred during the progress of chemical science, requiring an extension of this principle: an acid has been formed which contains less oxygen combined with sulphur than in the sulphurous, and this is called *hypo*sulphurous acid; and another containing more oxygen than the sulphurous, but less than the sulphuric, and this is termed *hypo*sulphuric acid. An acid has also been formed which contains more oxygen than the chloric—this has been called *per*chloric acid: the term is objectionable for reasons hereafter to be stated; *oxi*chloric is a better, and *hyper*chloric the best name. Although in the course of the present work some acids of minor importance will occasionally be mentioned, the following are those which, as being used either in scientific researches, in medicine, or the arts, will be more particularly treated of in their respective places:—

ACONITE, WINTER. [See ERANTHIS.]

ACONI'TUM, a genus of poisonous plants belonging to the natural order Ranunculaceæ. From very early times it has borne the same name, and has been known for the dangerous properties of many of its species. They are all hardy, herbaceous plants, many of them of great beauty; and are so easily cultivated, that one of them, A. Napellus, is found in every cottager's garden. The English call them *Wolf's-bane*, which name corresponds with the French *tue-loup* (kill-wolf). From all other ranunculaceous plants, Aconitum is at once known by its having the very large uppermost segment of its calyx overhanging the petals and other parts in the form of a helmet.

The common species, *A. Napellus*, is one of those in which the greatest degree of virulence has been found to reside.

Aconitum Napellus.

It is a native of Alpine pastures in Switzerland and other mountainous parts of Europe. Its leaves are very dark green, deeply cut into from five to seven long segments. The stem is about three feet high. The flowers are in long stiff spikes, and of a deep blue colour; they appear from May to July. All the parts of this plant are extremely acrid, especially the roots, which are scraped and mixed with food to form a bait for wolves and other savage animals. According to the observations of Orfila, the juice of the leaves introduced into the stomach occasions death in a short time; the root is far more energetic. The poison acts upon the nervous system, especially the brain, producing a sort of phrenzy.

These properties are probably found in all the species of the genus. *A. cammarum*, *lycoctonum*, and *anthora* are certainly equally dangerous. None of them, however, not *A. Napellus* itself, can be compared for fatal energy with the dreadful *Bikh* or *Bish* of Nepaul, the *Aconitum ferox*, which seems to possess the concentrated power of all the European species.

ACO'NTIAS, in Zoology, the name of a genus of serpents established by Baron Cuvier for the purpose of distinguishing certain species hitherto confounded with the *Angues*, or common snakes. but which recent observations have proved to differ from these animals in their habits and internal anatomy. The family of serpents which M. Cuvier denominates *Anguis*, differs from all other ápodal (footless) reptiles in certain peculiarities of osteology and internal structure, whereby they approximate more nearly to the lizards than to the true serpents. Some writers have even gone so far as to include them among the genera of the lizard family, whilst others are more inclined to consider them as forming a distinct and separate family of themselves, intermediate between the two. In fact, the generality of these animals, though externally deprived of feet, have yet an imperfect pelvis and a complete sternum, omoplate (shoulder-blade) and clavicle, concealed beneath the skin; their bodies are uniformly covered, both above and below, with small scales, as in the common lizard; and the osteology of the head is in all respects similar. But these characters, so unequivocal in other genera of the family Anguis, are for the most part wanting in the Acontias, which are thereby definitely distinguished, and form, as it were, the passage from the common snakes to the true serpents. It was upon these considerations that M. Cuvier was induced to establish this new genus. It is characterised by the absence of all the bones which represent the extremities in the other angues, while it retains the structure of the head common to these animals and to the lizards, and has the body similarly covered with small scales only, without the horny plates which guard its under surface in the common serpents, and protect them from injury in the various rapid motions which they perform.

As might naturally be expected from this conformation, the progressive movements of the acontias are very different from those of common serpents. They do not glide along the surface like these animals, but boldly carry their heads and breasts erect, and if closely pursued defend themselves courageously, and dart with the velocity of an arrow against their assailant. Though dreaded in their native countries, because confounded with their venomous congeners, these animals are perfectly harmless, and neither possess the means nor have the desire of being injurious. They have no poison fangs, and their cheek-teeth are so small as, in some species, to be barely perceptible. Their habits are gentle; and they are so timid that they generally fly at the least noise, or, upon the slightest appearance of danger, conceal themselves under some shrub or tuft of grass, or even bury themselves underground when no other refuge is at hand.

[Acontias Meleagris.]

The species belonging to this genus are, generally speaking, of a small size; and, as their mouths are not susceptible of the enormous dilatation possessed by the true serpents, they are incapable of swallowing any animal approaching to their own dimensions, and feed upon worms and insects. Different species of acontias are found in almost every part of the old world. The arid plains of Syria and Palestine produce a species which has been mentioned by the prophet Isaiah (c. xxxiv. v. 15), under the Hebrew denomination *Kippoz*, improperly translated *the great owl* in our common version of the Sacred Scriptures, but which the learned Bochart (*Hierozoicon*, pars post. lib. iii. cap. xi.) has shown to refer more properly to the acontias or anguis jaculus, the arrow or dart-snake of the Greeks and Romans. Other species inhabit Asia Minor, Egypt, and Persia; their singular mode of progression could not fail to attract the attention of the ancients, who often mention them by the appellation which M. Cuvier has lately revived. India and China have also their acontias; and the Cape of Good Hope produces a species without eyes.

Of the common Egyptian Acontias many fables are recorded by ancient authors, principally arising from confounding this really harmless species with the more deadly and venomous serpents of the same localities. Agatharchides, Diodorus, and Strabo, call the Acontias the most poisonous of all serpents, and consider its bite to be absolutely incurable; Ælian relates that it will occasionally spring to the distance of twenty cubits; Galen, Isidorus, and others, say that it lurks among the branches of trees, from whence it darts suddenly upon whatever animal happens to come within its reach; and Avicenna even adds that it propels itself with so much force in these formidable springs, as to bury itself, like an arrow, in the body of its victim. All these fables, and many others recorded of this serpent, plainly arise, partly from the habits and mode of progression peculiar to the Acontias, and partly from confounding it with the Cerastes, or horned viper, the Dipsas, Asp, and other Egyptian species. Nor have the poets failed to contribute their share to the general stock of wonders related of this animal. Lucan, for instance, often mentions it with many of the attributes above recorded; and indeed its natural habits, without the aid of imaginary qualities, are too remarkable to be overlooked, even by the most inattentive observer.

It is no part of our plan to give a complete enumeration of the species which have been described as belonging to this or any other common genus of reptiles. Such a dry and formal catalogue would possess few charms for the general reader, and be of little use to the scientific zoologist. We must, therefore, refer those who are desirous of further information concerning the names and descriptions of these serpents, to the works of Merrem, Schneider, Lacepede, and Daudin, where their curiosity will be amply gratified.

ACORINÆ, in Botany, a section of Aroideæ, which see.

ACORN, the English name of the fruit of the oak. [See Quercus.]

A'CORUS, the botanical name of the plant that produces the drug called in the shops *Calamus aromaticus*. It belongs to the natural order Aroideæ, in the acrid properties of which it participates in a slight degree, and is found abundantly in the fresh-water marshes of many parts of England. It has a perennial, creeping, horizontal stem, as thick as the finger, the whole of the under side of which emits roots into the mud or soft earth, in which the plant uniformly grows. From this spring many deep-green, sword-shaped leaves, about three feet long. In the midst of all is a leaf-like stem, from below the point of which protrudes a cylindrical, or rather conical, spadix of greenish flowers, which are so closely packed together, that the stalk is not to be seen. The leaves when bruised are fragrant; for which reason they were formerly employed to strew the floors of rooms, or of churches, under the name of rushes. This practice is still maintained in some places, where the plant is common, as at Norwich, the cathedral of which city is strewed with sweet rushes upon certain high festivals. The flowers are so seldom produced, that it is a common belief that they never are borne. *Calamus aromaticus* is slightly aromatic, and is occasionally used as a stimulant; but is of very little importance. The part employed is the dried creeping stem, or, as it is improperly called, root.

[Acorus Calamus.]

ACOSTA (JOSEPH D'), a Spanish writer of the sixteenth century. He was born at Medina del Campo in Leon, about the year 1539; and, before attaining the age of fourteen, entered the Society of the Jesuits, to which his four elder brothers already belonged. He was remarkable, while pursuing his academic studies, for his diligence and his rapid progress both in literature and science; and on finishing his course, he became Professor of Theology at Oraña. This situation he retained till 1571, when he was dispatched as a missionary to South America. He was eventually made provincial of his order at Peru; and did not return to Spain till 1588. During his residence in South America, he had employed part of his time in writing an account of that continent, which was published at Seville, in 4to. in 1590, under the title of *Historia Natural y Moral de las Indias*. This work, which has been often reprinted (the edition of 1591, in 8vo., having received considerable corrections and additions from the hand of the author), is highly esteemed as an authority on the early condition of South America. It has been translated into French, Italian, German, Dutch, and English. The English translation, which appeared at London, in 4to., in 1604, and again in 1684, bears to be performed by E. G., supposed to be the initials of Edward Grimestone. There is also a Latin translation of the work in Part IX. of De Bry's *Collectiones Peregrinationum in Indiam*. Acosta, after his return to his native country, became a great favourite of Philip II., and had successively the dignities of Visitor of his order for Arragon and Andalusia, Superior of Valladolid, and Rector of the University of Salamanca. While holding this last situation he died on the 15th of February, 1600. Besides the work we have mentioned, he is the author of another on the same subject, published in 1589 in Latin, under the title of *De Natura Novi Orbis Libri Duo*, which was afterwards translated by himself into Spanish, and inserted in his history. He is also the author of several theological treatises; and, among the rest, of a volume of sermons, in Latin.—[*Moreri — Biog. Univ. — Robertson's America — Biblioth. Scriptor. Soc. Jesu, a Ribadeneira, Allegambe, et Sotvello.*]

ACOTYLE'DONES, or ACOTYLEDONEÆ, the name of the first class in Jussieu's Natural System of Botany. It is derived from the circumstance of all the plants which it comprehends vegetating without the aid of the seed lobes called cotyledons. Such plants are also in all cases destitute of flowers, and are in fact the same as what Linnæus called *Cryptogamous*. It having been found, by more recent and exact observations —1. That many plants, that really do bear flowers, have no cotyledons; and 2. that all flowerless plants are altogether destitute of seeds, so that they might as well be named *aspermous* as *acotyledonous*, because cotyledons can only be present in seeds strictly so called, the term Acotyledones has fallen into disuse, and Cellulares has been substituted for it, which see.

ACOUCHY, a small species of Cavy, sometimes called the Surinam Rabbit.—(See Agouti.)

ACOUSTICS, a word derived from the Greek, and signifying, the science of hearing. In treating this, and all other general scientific terms, we shall confine ourselves to the elucidation of those first principles, without which the applications cannot be understood; noticing the application only so far as their mention can be made serviceable in explaining and referring to particular articles for more specific information. Thus the reader must consult the articles Pipe—Chord—Vibration—Harmonic—Speaking Trumpet—Ear—Larynx—Echo, &c., for many explanations, which it would be necessary to insert here, if we were writing a treatise on acoustics.

We need not say what sound is, or dwell on the fact that some sounds differ only in intensity or loudness, as the reports of a cannon and a musquet; others in musical pitch, as two notes of the same instrument; others again in character or tone, or, as the French call it, *timbre*, such as the same note sounded on a flute and a trumpet. This being understood by all, we proceed to inquire what is the agent in conveying these different sounds to the ear; in what ways it is acted upon in sounds of different loudness, tone, or character; and how far we can explain a most remarkable phenomenon, though not generally believed to be such, on account of the frequency of its occurrence, viz., that we can hear and distinguish, at the same time, almost any number of different sounds. Unfortunately, our knowledge is limited by the nature of the question, which requires the improvement of one of the most difficult branches of mathematical analysis; and by our very imperfect knowledge of the constitution of matter, and the effect which putting in motion some particles of a body has upon the rest. Strictly speaking, we ought to say that sound has no existence except in the ideas of the hearer; but, in accordance with common phraseology, we shall speak of a body as *sounding* when it is in that state in which it would produce the impression of sound, if the proper medium were placed between it and the ear.

No body can produce a sound, as we know from observation, unless its parts be put into rapid motion. We have evidence of this in a tuning fork, the string of a musical instrument, the parchment of a drum, &c. Neither will any sound be perceived unless there is a continual supply of solid or fluid matter, possessed of a moderate degree of elasticity, between it and the ear. Thus a bell, when rung in an exhausted receiver, hardly yields any sound; and the small portion which it does give may be altogether destroyed or materially diminished by lining the receiver with cotton or wool. The air is generally the medium through which sound is conveyed; but only because this is most commonly the one with which the *tympanum* or drum of the ear is in direct communication. A bell rung under water has been very well heard at a distance of 1200 feet by an observer with his head under the same body of water; those who work in one shaft of a mine can often distinctly hear the sound of the pickaxe in another shaft through the solid rock; and persons wholly deaf, who therefore are not at all affected through the ear, have received pleasure from music, by placing their hands upon a shutter or other solid body near the instruments. We confine ourselves particularly to what takes place in air.

The body of air which surrounds us produces no sound if it be all moved together, that is, if the velocity of all its particles be the same. The highest wind makes no noise except when it is forced against some obstacle, and the sound of a cannon is heard in whatever direction the wind may blow. Neither does the strongest band of music produce any sensible wind in any direction. It is therefore unto some other sort of motion that we must look for the agent of sound, and the manner in which sonorous bodies move immediately points it out. If a tuning fork or a string be struck, a rapid succession of vibrations is the consequence, which, as we shall see, causes the particles of air to vibrate in a similar manner. And we find, that in order to produce a note, not only must there be a succession, but a *rapid* succession, of vibrations; experiments show that the ear is not capable of receiving the impression which we call sound, unless the particles of air in contact with it vibrate at least thirty times in a second. The vibration produced in the particles of air by a sonorous body may be distinctly proved by the following experiment. Let a tuning fork be sounded, and while yet in vibration, let it be stopped by the finger. A sensation will be felt for an instant, for which we have no name in our language, arising from the prong of the fork rapidly, but gently, striking the finger, and very different from that produced by merely touching the fork when at rest. Now, blow into a common flute, stopping two or three of the higher holes, gently. The same sort of sensation, though in a much smaller degree, will be felt on that part of the fingers' ends which is in communication with the interior air. The fingers should be warm, and if the observer be not used to the instrument, the effect is made more certain by tuning the string of a violoncello to the note which is to be fingered on the flute, and then sounding the former strongly, while the latter is held over it, with the fingers placed as before. That any very violent and sudden noise produces a concussion in the air even farther than the sound can be heard, is proved by the fact, that the explosion of a large powder-mill will shake the windows in their frames for nearly twenty miles round.

We now proceed to describe, as far as the same can be simply done, the motion which takes place in the air when the impression of sound is communicated; and here we stop to explain a method of making the eye help the reason in many cases. Suppose we wish to register what takes place in the vibration of a spring, of which the position of rest is AB, but which, having been set in motion, (*Fig.* 1,) passes through all positions between AC and AD. The spring being at AC, and the finger or other disturbing cause being removed, the elasticity of the metal makes continued efforts to restore it to its first position AB, by which it is made to move, and with continual accession to its velocity, until it actually does arrive at AB where, if the velocity were suddenly destroyed, it would rest. But the velocity still continuing, the spring continues to move towards AD, with a change of circumstances, inasmuch as the elasticity, now opposing its motion, gradually destroys the velocity by the same steps as it was before gradually created; so that when the spring comes to AD, it will be again at rest, but will not continue so, since the elasticity will cause the same phenomena to be repeated, and the spring will move back again towards AC. But for friction and the resistance of the air it would again reach AC; it does not, however, get so far, owing to these causes, which always diminish, and never increase, velocity. This alternation will go on until the spring is reduced to a state of rest. Similar phenomena occur in the motion of a pendulum, of the string of a harpsichord, and generally, wherever small vibrations are excited in a body, which remove it, but not much, from its position of rest. We might, perhaps, conclude, that each successive oscillation is performed in a shorter time than the preceding, seeing that a less space is described by the spring. But this is not the fact: it can be observed, as well as demonstrated, that the oscillations which take place before a body recovers the effects of a small disturbance and resumes the state of rest, are severally performed, if not in the same time, yet so nearly in the same time, that the difference may be entirely neglected in most practical applications: for the reason of which, see Oscillation. Such being the case, we may omit the effects of friction and resistance, so far as the *time* of vibration is concerned, and consider the spring as describing exactly the same path in each successive vibration. Let DC be the line described by the top of the spring, which we may call a straight line, since it is very nearly so, and while the spring moves from D to C, imagine a curve DyC to be drawn, in such a way that, the spring being at x, the perpendicular xy is the rate per second at which the top of the spring is then moving. A little attention will show that the curve we have drawn represents the various changes of motion just alluded to: thus TB, the greatest perpendicular, is over the point B where the spring moves fastest; and at D and C there is no perpendicular, the spring coming to rest when it reaches those points. During the return from C to D, in which the motion is the same, but in a contrary direction, let a similar branch CtD be drawn, on the other side of CD. We will call the whole curve DTCtD the *type* of the double vibration of the spring, the two branches being the types of its two halves. Now, suppose a column of air inclosed in a thin tube AB, which is indefinitely extended towards B, but closed at A by a piston which moves backwards and forwards from A to C, and from C to A, after the manner of a spring, the type of its motion being represented by the curves on AC. And first let the piston be pushed forward from A to C. If the air were solid, we should say that a column of air AC in length would be pushed out of the end B of the tube (*Fig.* 2.), in the time in which the piston is driven in. As to how far we should be justified in saying so, we refer the reader to the article Elasticity; we certainly can have no notion that such an effect would be produced upon a column of elastic fluid like the air. Experiment, as well as mathematical demonstration, show us that though every particle of the fluid will finally be put in motion, yet that those particles which are nearer the disturbing piston receive their first impression sooner than those which are more distant; and we find that this successive *propagation*, as it is called, of the disturbance, goes on *uniformly* at the rate of about 1125 feet in a second, the temperature being 62° of Fahrenheit; for example, a second must elapse before those particles, which are 1125 feet distant from A, will have their first news, so to speak, of what is going on at A, and in the same proportion for other distances. It is also shown that the velocity of communication is not affected by the greater or less degree of violence with which the air is struck, but remains the same for

Fig. 1

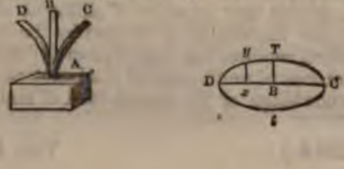

Fig. 2

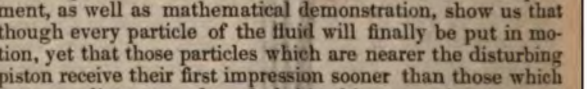

every sort of disturbance. With such a velocity, we may see that the column of air made up of all the particles which feel, or have felt, the effects of the disturbance, must be very long when compared with A C, the extent of an almost insensible vibration; so that it will lead to no sensible error if we suppose that the effect of the piston at every point of its course is propagated instantaneously to C, and from *thence* only, with the velocity of 1125 feet per second. We will now consider what this effect is. Divide the whole length A C, *fig*. 3, into a large number of very small parts, *described in equal parts*, and instead of the piston moving continuously, and with imperceptible changes of velocity, along A C, let it move by starts from each point to the next, with the proper increase or decrease of velocity. In the figure we have divided A C into ten parts, but the same reasoning applies to any greater number, and the reader may refer to ACCELERATION for an instance in which the truth, as regards motion gradually increased, is come at by a similar supposition. We have much enlarged A C (*Fig*. 3), to give room for the figure: the reader may help his ideas by supposing that A C is viewed through a powerful microscope, and the rest of the tube by the naked eye. Whatever may be the common time of moving through each of the parts A 1, 1 2, &c., the portions of the column affected by the starts of the piston will be of the same length, and each will be as much of 1125 feet as the time of each start is of one second. Set off the lengths C P, P Q, Q R, &c., each equal to this length, and for the present let us agree to call the common time in which the piston starts through A 1, 1 2, &c. an *instant*. The reader must bear in mind throughout that we intend to carry the supposition of dividing A C into parts to its utmost limit, by which we shall have to suppose C P, P Q, &c. very small, though still great when compared with A 1, 1 2, &c. We also think it right to repeat, that all the figure on the left of C is immensely magnified, and that the propagation is supposed to be instantaneous from 1, 2, &c. to C. In the first *instant*, the piston moves through A 1, with the velocity *p* 1 per second, and forces the column of air A 1 into C P, which, therefore, has its density increased, or is compressed, the air which was held in C P and A 1 together being now confined in C P. As the propagation has not travelled farther than P, the effect is just the same as if there had been a solid obstacle at P during the first instant. The portion C P is then compressed, strictly speaking, *unequally*, that is, the parts near to C are more compressed than those near to P; but on account of the small length of C P, and the rapidity of the transmission, we may suppose all the parts equally compressed. Again, the particles near C begin to move towards P, and for a similar reason we may suppose the velocities of all the particles the same; this velocity being that of A during the first instant. The reader must not confound the absolute velocity of the several particles, which is always small, with the rate at which they transmit their velocities and compressions, which is very great. We will use the phrase that the portion C P has received its *first compression*. If the piston were stopped at the end of the first instant, the whole effect upon C P would be transferred to P Q in the second instant, both as to compression and velocity, and the particles of C P would return to their first state, and receive no further modification. But in the second instant, the portion C P receives its *second compression*, which is greater than the first, since a column 1 2 longer than A 1 is forced into it. Similarly the velocity is increased, being 2 *q* per second instead of 1 *p*. If the spring were then stopped, the third instant would see the portion P Q transmit its velocity and compression to Q R, C P to P Q, and C P would resume its natural state. But in this instant, C P receives its third compression, which is greater than the former two, and the same process goes on, each portion transmitting its velocity and compression to the *succeeding* one, receiving in its turn more than it parted with, from the *preceding*. This continues until the piston has reached the middle point of A C, after which the compression of C P still continues, but becomes less and less in successive instants, because 5 6, 6 7, &c. down to 9 C decrease in length, in the same way as A 1, 1 2, &c. increased. When the piston begins to return through C 9, in the eleventh instant, the portion C P receives its *first rarefaction*; for the air in C P now occupies C P and C 9; the particles in C P therefore move towards C instead of from it, and the preceding modifications are successively repeated in *quantity*, but changed into their contraries; that is, each portion undergoes successive rarefactions, equal in amount to the former condensations, and the particles move *towards* C with the same velocities which they formerly had *from* C. This continues until the piston reaches A again, after which the same phenomena recommence in the same order. Thus it appears that the absolute velocity of each particle is in the direction of the propagation so long as it is compressed; but in the contrary direction, when it is rarefied, and that each particle, during the progress of a double series of compression and rarefaction, moves forward in the direction of propagation, and back again to its former place, where it rests, unless a third vibration follows the first two. When we talk of the compression of a particle, we mean that it is nearer the succeeding particle, than it would have been in its natural state; and *vice versâ* for rarefaction. We may represent these phenomena in the following table, which, to save room, is made on the supposition that A C was divided into four parts, and might be equally well constructed if the number of parts into which A C was divided had been greater. The numbers in the top horizontal line are the successive portions of the tube, those in the left vertical column the successive instants of time, and under any portion of the tube, opposite to any instant of time, will be found the state in which that portion of the tube is at that instant of time: 1 denoting its first compression; 1′ its first rarefaction; these latter numbers recommencing when a complete cycle of changes is finished. The blanks denote that the effect has not yet reached the corresponding particles.

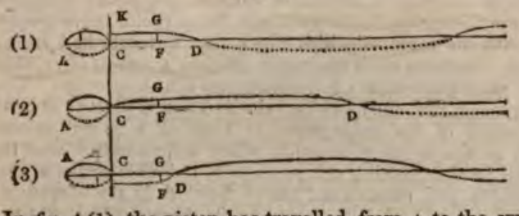
16	4′	3′	2′	1′	4	3	2	1	4′	3′	2′	1′	4	3	2	1

On casting the eye down any vertical column, we see the state of the same portion in successive instants of time: on looking along a horizontal column, we see the state of all the portions of the tube at the same instant, as far as the effect has reached them. Doing the latter, we see that all the successive states are continually repeated, in such a way that whatever states two portions may be in, the intermediate portions have all the intermediate states. There is also at the beginning an unfinished series in process of formation. If we look down a column, we see that any one particle successively undergoes the different states, from the moment when the effect first reaches it. We shall now suppose the division of A C to go on without end, and examine the final result. The different states of compression or rarefaction will then become more and more numerous, but the difference of quantity between each and its preceding will become less and less, so that when we at last give to the piston a *continuous* or gradually increasing and decreasing velocity, we must also suppose a continuous or gradually increasing and decreasing compression or rarefaction of the air in the tube. This being premised, we return to the figure, and construct the *type* of the motion of the piston, both backwards and forwards, and also the *type* of the state in which the particles of air actually are for two or three several positions of the spring;

as in the figure below, which we proceed to explain. (*Fig.* 4.)

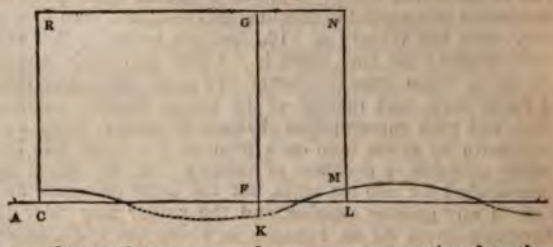
Fig. 4.



In *fig.* 4 (1), the piston has travelled from A to the small perpendicular, through something more than a quarter of a vibration: the first disturbance has reached D, and the curve D K is the *type* of the state of each particle as to velocity; that is, the perpendicular F G is the rate per second at which the particle F is moving from C, and the same for every other perpendicular.

If the piston be performing its third complete vibration, or its second vibration *forwards*, there will have been a preceding series of compressions and rarefactions propagated onwards, as in the figure 4 (1). In *fig.* 4 (2), a vibration forwards has been completed; the curve on C D now represents a complete undulation, as far as the compressions are concerned. In *fig.* 4 (3), the return of the piston has commenced, and the particles between C and D are rarefied, and moving towards C; this we explain by placing the *type* beneath the tube, and dotting the curve; F G expressing the velocity per second of the particle F towards C. The length of the whole wave C D is easily calculated. If, for example, the single vibrations of the piston are made in $\frac{1}{100}$ of a second, the first impulse will have travelled through one hundredth part of 1125 feet, or 11¼ of a foot. This is the length of C D, in *fig.* 4 (2). The complete series of compressions is called a *wave of compression;* and that of rarefactions a *wave of rarefaction.* And the same type which represents to the eye the velocities of the various particles, will also serve to represent the degrees of compression or rarefaction. For those particles which are moving quickest from C are most compressed, and those which move quickest towards C are most rarefied. In returning to figure 3, we see that A 1, 1 2, 2 3, &c., are spaces described in equal times, and are therefore in the same proportions as the velocities, that is as 1 *p*, 2 *q*, 3 *r*, &c. But these spaces, in the preceding explanation, are proportional to the degrees of condensation; these latter then are proportional to the velocities. If, then, we suppose the series of compressions and rarefactions to have gone on for some time, and an unfinished wave of compression to have been formed at the instant we are considering, we may represent the whole state of the particles in the tube at that instant by the following figure—(*Fig.* 5):—R G N is a line parallel to the tube, and therefore G F is of the same length for all positions of F. It is to be made 1125 feet in length. Its use depends upon the following proposition:—That in the simple undulation which we are now considering, so long as the disturbance is small, the velocity of any particle bears to the *velocity of propagation* (two very distinct things, as we have before observed) the same proportion as the change in the density bears to the density of undisturbed air. This follows from the investigation attached to *fig.* 3: for, in the fourth instant for example, the column 3 4 of air is forced into C P, and 3 4 and C P being spaces described in equal times with velocities

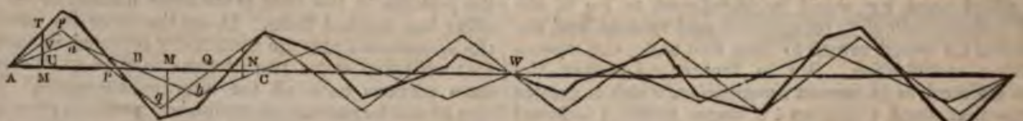
Fig. 5.



4 *s* and 1125 feet per second, are spaces proportional to these velocities. And the compression will be the same if we increase C P in any proportion, provided we increase the quantity of air forced into it in the same proportion. A similar proposition holds for rarefactions. Or, in other words, F K being the velocity with which the particle at F is moving *towards C*, the rarefaction of the particles at F is that which would be obtained by allowing the air naturally contained in a tube G F, 1125 feet long, to expand into the length G K. Similarly, the compression at L is that which would be obtained by compressing the air in a tube N L into the shorter tube N M. If we wish to see the state of these particles at any succeeding instant, let the *curvilinear* part of the figure travel uniformly forward at the rate of 1125 feet per second, new curves being continually formed and finished at C: we shall thus have the state of the whole tube at any succeeding moment. Before proceeding to apply this explanation to the phenomena of sound, we must see what will take place if the tube be agitated by several different undulations at once.

All readers, however little acquainted with Mechanics, are aware, that if a body be impressed by two forces in the same direction, it will proceed with the sum of the velocities produced by the two forces; and with the difference of the velocities, if the forces strike in contrary directions, the motion in the latter case being in the direction of the greater of the forces. Hence, if there be different undulations excited in the same column of air, the velocities of each particle will be made up of the *sum* or *difference* of those which it would have received from each undulation, had each acted alone; the *sum* when it would have been compressed by both, or rarefied by both, and the *difference* when it would have been compressed by one and rarefied by the other. And the compressions or rarefactions being proportional to the velocities, a similar proposition will hold of them. Underneath we have represented the state in which a column of air would be at a given instant from two different waves, the types of which are drawn, and the broad line is the type of their united effects. We know [see INCOMMENSURABLE] that any two lengths are either in the proportion of two whole numbers, or if not, two whole numbers can be found, which are as nearly proportional to them as we please. We have, to take a simple case, drawn the lengths of the waves in the proportion of 5 to 4. (*Fig.* 6.)

Fig. 6



The types of the waves are different portions of straight lines, one whole condensation and rarefaction taking place, as indicated by A *a* B *b* C in the first, and by A *p* P *q* Q in the second. We suppose the waves to commence together. This supposition, of the condensation and rarefaction proceeding in such a way that their types shall be parts of straight lines, is not to be obtained in practice, since, as we have seen, such motion as that of a spring, and we may add of a string or drum, would produce regular curves. But it is as allowable in illustrating the effects of combined undulations as any other; and if, moreover, we round the corners of the types of the single waves, thus making them present an appearance similar to that in the preceding figures, a slight rounding of the corners of the broad line will show sufficiently well what the combined wave would have been, if the preceding figures had been rounded. And the supposition of rectilinear types facilitates the drawing of such figures, (which we would recommend to our readers,) since, as they will observe, the type of the combined wave consists also of portions of straight lines which break off only when the type of one of the single waves changes from one line to another. The general rule for forming the broad line, derived from a preceding observation, is —let the perpendicular or ordinate [See ABSCISSA] be the *sum* of the perpendiculars of the types of the waves, when they fall on the *same* side of A P, and the difference when they fall on different sides; observing, in the latter case, to let the broad line fall on the side of that wave which has the greatest perpendicular. Thus at the first M, M T is the sum of M U and M V, and particles at M are in a greater state of compression than the first wave would give them, which arises from the second; similarly at the second M there is an increase of rarefaction. At N, the air is compressed by one wave, and rarefied by the other, but more compressed than rarefied. At P, B, Q, C, &c., where one of the waves causes neither compression nor rarefaction, the broad line coincides with the other wave.

On looking at the figure thus produced, we see—

1. That it is composed of a cycle of successive compressions and rarefactions, in which, however, the rarefactions differ in kind from the preceding compressions; so that we must not give the term *wave* to each set of compressions or rarefactions, as we reserve this word to denote cycles of changes, which are following by similar cycles of contrary changes.

2. That when the lengths of two waves are as five and four, four of the first will be as long as five of the second; so that the waves recommence together at W, but not exactly as before, the wave of condensation from the first being accompanied by the wave of rarefaction from the second. This difference, however, is not found at the end of the second similar cycle of four and five; so that after eight of the first waves, corresponding to ten of the second, the combined wave begins again to have the same form as at first.

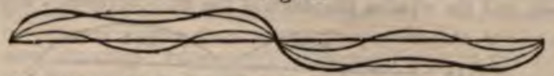
3. The complete cycle denoted by the broad line may be divided into two, joining at W; in the second of which a series of rarefactions is found similar to every series of compressions in the first, and *vice versâ*. We may, therefore, give the name of wave to the part of the broad line intercepted between A and W, consistently with our definition of this word.

4. If the waves had not begun together, a wave would have resulted of the same length as the preceding, if we began at any point where the compression from one was exactly compensated by the rarefaction from the other.

5. If both waves had been of the same length, the resulting wave would have had that length; or if the first wave had been contained an exact number of times in the second, the resulting wave would have been of the length of the second.

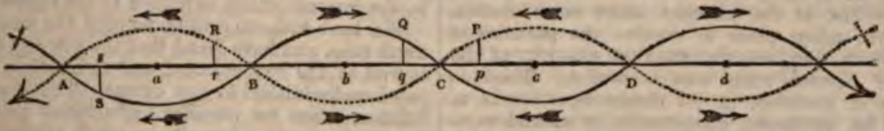
We subjoin a cut, representing a wave contained three times in another wave, and the resulting wave. (*Fig.* 7.)

Fig. 7.



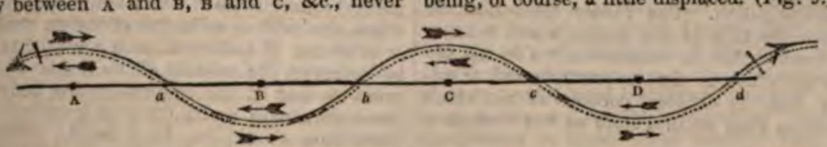
We have hitherto considered combined undulations as propagated in the same direction: let us now take two waves of equal lengths propagated in opposite directions, arising, as we may suppose, from two pistons, one at each end of the tube. After a certain time, depending on the length of the tube, two waves will meet, by which we mean that the particles will begin to be affected by the motion of both pistons, and the manner in which the joint effect is represented is the same as before, though the phenomena are very different. In the former case, having represented the resulting wave at one instant, we could trace the change of state throughout every particle of the fluid, by supposing the type of that resulting wave, or a succession of such types, to move along the tube at the rate of 1125 feet per second; in the present case, the waves are propagated in contrary direction, so that any given effect from the first wave is no longer continually accompanied by another given effect from the second wave. We must also recollect, that the motion of the particles in each wave of compression is in the direction of the propagation; so that a particle under the action of two waves of compression, has opposite velocities impressed upon it, and therefore moves with the difference of the velocities; and so on.

Fig. 8.



Now let A, B, C, D, &c., be the points where the two series of waves meet in the axis, and let us choose the instant of meeting for the time under consideration. Let the continued line represent the waves propagated from left to right, and the dotted line those propagated from right to left, as marked by the arrows at the parts at which they end; the arrows above them representing the directions of the absolute velocities which the waves over which they are placed give to the particles. (*Fig.* 8.) All the particles are now neither compressed nor rarefied; for it is evident that, whatever condensation or rarefaction a particle experiences from the wave moving to the right, there is a contrary rarefaction or condensation from that which moves to the left. But every particle has the velocity derived from either wave doubled by the other. Again, the particular points A, B, C, D, &c., are never put in motion; for it is plain that by the time any point P comes over C, giving it the velocity of P*p* to the left, the point Q, similarly placed on the other wave, will also have come over C, giving it the equal and contrary velocity Q*q*; so that, as far as velocity is concerned, all the impression produced on A, B, C, D, &c., is equivalent to two equal and contrary velocities, or to no velocity at all. But when P has come over C, the compression, answering to P*p*, is doubled by that answering to Q*q*. So that the particles at A, B, C, &c., undergo no change of place, but only condensation or rarefaction. Also the particles at *a*, *b*, &c., halfway between A and B, B and C, &c., never undergo compression or rarefaction, but only change of velocity. For by the time any point R, from one wave, has come over *a*, with the condensation answering to R*r*, S will have come over it from the other, with the equal rarefaction answering to S*s*; so that the effect of the combined waves upon *a*, is always that answering to equal condensation and rarefaction, or no change at all. But the velocities answering to R*r* and S*s* are equal, and in the same direction; so that the points *a*, *b*, &c., have the velocities which one wave would have given them doubled by the other. Hence at *a*, *b*, *c*, &c., the particles suffer no change of state, but are only moved backwards and forwards. Now, let the time of half a wave elapse, in which case the types of the undulations will coincide, and those parts will be over the capitals on the axis, which are now over the small letters, and *vice versâ*, as in *fig.* 9, where the coincidence is denoted by a continued and dotted line together, the latter being, of course, a little displaced. (*Fig.* 9.)

Fig. 9.



Half a wave since, all compression and rarefaction had disappeared throughout the tube, the velocity of every particle being double that which either wave would have caused. The case is now altered; no particle has any velocity, since there are the signs of equal and contrary velocities at every point of the tube; but every particle is either doubly compressed, or doubly rarefied, except *a*, *b*, &c., which, as we proved, are never either compressed or rarefied. In one more half wave, the phenomena of the first supposition will be repeated; that is, all condensation or rarefaction will be destroyed throughout, the particles, however, being all in motion, except A, B, &c., but in directions *contrary* to those they had at first; while, at the end of a fourth half wave, the phenomena of the second supposition will be repeated, that is, all velocity will be destroyed, the particles being all *condensed* or *rarefied*, according as they were before rarefied or condensed. The reader may easily convince himself of these facts by drawing the corresponding figures. To put the results before the eye, suppose the tube to be of a highly elastic material (thin Indian rubber, for example), so as to bulge outwards a little when compressed from the interior, or to contract in diameter by the pressure of the outward air when the inward is rarefied. Recollect, also, that A, B, C, D, &c., remain without motion, their only change being condensation or rarefaction; while *a*, *b*, *c*, &c., are never compressed or rarefied, their only change being that of place. We exhibit side by side the successive appearances of the tube, and the relative situations of the types between A and C, the arrows always representing the direction of the motion of the particles. A half-wave elapses between each two configurations. (*Fig.* 10.)

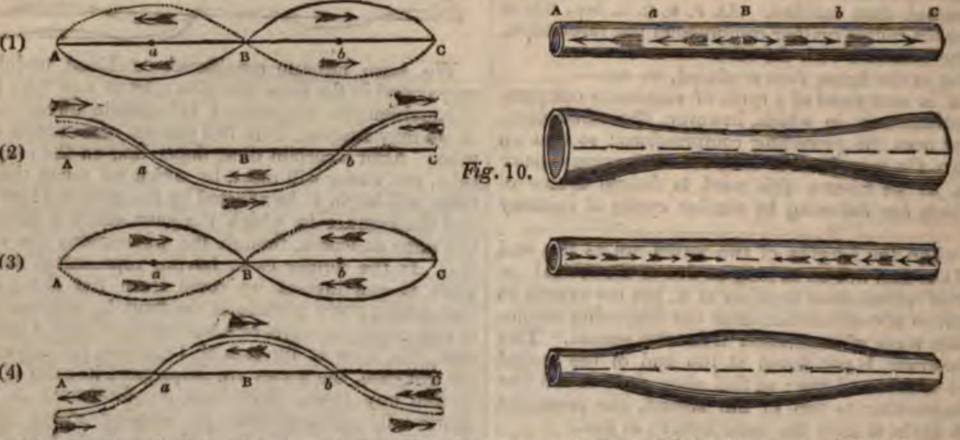


Fig. 10.

These phenomena will recur in the same order, and this mode of undulation, though it is necessary to show how it arises from the combination of two waves, is nevertheless more easy to be explained by itself than either of these two. For if we recollect that when particles of air move away on both sides from a given point, there must be a condensation in the parts towards which they move, and a rarefaction in those which they quit, (2) will evidently follow from (1). At this second period, the elasticity of the air will have opposed and destroyed the velocities of the particles; so that there now only remains a tube of particles at rest for the moment, condensed towards the ends and rarefied in the middle. There will, therefore, immediately commence a rush of air towards the rarefied parts, which will end by producing the state represented in (3), where equilibrium is restored, as far as compression and rarefaction are concerned; but where, at the moment under consideration, nothing has yet taken place to deprive the particles of the velocity which they received from the elasticity of the air before the natural state was recovered. There is now a motion of particles, in all directions, towards B, which will go on producing compression at B, and rarefaction at A and C, until all the velocity is destroyed. This is the state represented in (4), from which (1) follows again; and so on. The states of the column intermediate between the times of (1), (2), &c., are easily imagined. Between (1) and (2) the compression at the extremities will have begun; but not yet to the complete destruction of the velocities. Between (2) and (3) the motion of the particles towards the middle will have begun; but will not yet have placed them in their natural positions; and so on. The particle at B is evidently never in motion, being always equally pressed on both sides. The same would be seen of A and C, if the tube were extended on both sides.

It is evident also, that except at the instant when compression and rarefaction are all destroyed, there must be a point at which the transition occurs from condensation to rarefaction; and *vice versâ*. It is not, however, so evident, in this way of viewing the subject, that these points always remain in the same position at *a* and *b*, which is the result of our previous investigation. The reader must however recollect, that, when we talk of the points *a* and *b* being always free from condensation or rarefaction, we do not say that it is *the same air* which is always uncondensed or unrarefied, but only that the different portions of air, which pass by *a* and *b*, are in their natural state at the instant of the passage.

Now it must be evident, that if, in the motion of a fluid, there be certain particles which remain at rest, it is indifferent whether we suppose those particles to be fluid or solid; for all that we know of a solid, as distinguished from a fluid, is, that the particles of the latter yield *sensibly* to any applied force, while those of the former do not. Hence, when such impulses are communicated to a fluid, that some of its particles must remain at rest, the question never arises, so to speak, as to whether those particles would, or would not, move with the fluid, or resist, if the conditions of motion were so altered, that forces, which did not counterbalance, would be applied to those particles. Let us now suppose that a solid diaphragm is stretched across the tube at A; the motion will still continue exactly as before; and we may produce this species of complex undulation by a piston at one end only of the tube, provided the other end be closed. For, on this supposition, all the successive states into which the air at the end furthest from the piston is brought, cannot be communicated to the outside air, and must, therefore, be either retained, or returned back again through the column of air. The latter effect results; and the returning wave, which is of the same kind as the advancing wave, produces the phenomena just explained. If A and B were both closed during an undulation, no piston would be necessary, if it were not that there is no substance but what will vibrate in some small degree, and the vibrations communicated to the tube from the internal air gradually destroy the internal motion, by the communication of motion to the external air.

We have hitherto considered only the motion of air in a small tube, and have found that the velocity of the particles, as well as the condensation and rarefaction, may be propagated undiminished to any extent. The case is somewhat different when we consider undulations propagated in all directions at once. Imagine a small sphere, which is uniformly elastic in every part, and which, by some interior mechanism, is suddenly diminished in its dimensions, and afterwards as suddenly restored. A wave of rarefaction and condensation will be propagated in every direction; which wave, at any instant, will be contained between two spheres, concentric with the sphere already mentioned, the radii of which differ by the length of the double wave: at least, unless there be some reason in the state of the atmosphere, why the propagation should take place more quickly in one direction than another. We have no reason, at first sight, to suppose that the velocity of propagation would be exactly, or even nearly the same as if a portion of the air through which the waves pass had been contained in a tube, unconnected with the exterior air. But it is found, both by mathematical analysis and experiment, that the velocity of propagation remains unaltered in both cases; and also that the *absolute* velocities of the particles diminish. This last is a natural consequence of a very simple principle—namely, that when one body, or collection of bodies, strikes a larger body, or collection of bodies, in such a way that its whole motion is destroyed, the velocity of the larger body will not be so great as that of the communicating body, but less in the same proportion as its mass is greater. The law of this diminution should be, from theory, *inversely as the distance;* that is, by the time the wave has moved from 3 miles to 5 miles, the compressions and velocities should be as 5 to 3; but we have no direct means of submitting this to experiment, the absolute velocities being imperceptible.

We now proceed to the application of these principles. We know that when the air is violently or rapidly propelled in any direction, that undulations such as we have described are produced, and that the impression called sound is produced also. When a gun is fired, the great elasticity of the gases which are disengaged by igniting the gunpowder, forces the air forward out of the gun, which the instant afterwards is allowed to return. If feathers or dust be floating in the air, they have been observed to move forwards, and then back again, just as we have found the particles of air around them would do in the course of a double wave. The intensity or loudness of the sound seems to depend upon the greatest absolute velocity of the particles, and not at all upon the velocity of propagation, which is found to be the same for all sounds. Thus in a musical chord, spring or drum, the harder the metal or parchment is struck, the louder is the sound, but without any difference of tone, character, or velocity of propagation. There is no instrument of which the sound may not be made louder or weaker without any other change than giving greater velocity to the immediate cause of sound. We will not enter further into this part of the subject than to observe, that, generally speaking, we are not authorized to say that sound travels with equal loudness in all directions. It might do so in the case where it was communicated by the sudden contraction and expansion of an elastic sphere, as above supposed; but this is a supposition which we cannot put in practice. If a tuning fork be sounded and turned round in the hand while held up before the ear, very perceptible diminutions and augmentations of loudness will be perceived.

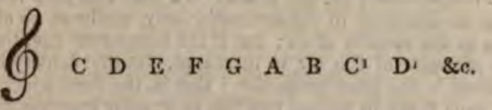
The immediate communicator of sound is the tympanum or drum of the ear, an elastic membrane, which is set in vibration by the motion of the particles of air against it, and vibrates in the same time with them. The impression is conveyed to the brain by certain neighbouring nerves. [See Ear.] We might expect, that when the wave of sound is of considerable length, we should hear its different parts, that is, feel a difference between the beginning and end where the velocities and compressions are small, and the middle where they are greatest. This happens to a small extent, in the difference, for example, between the 'roar' of a cannon and the 'report' of a musket. No explanation can convey a better idea of the difference than these two words. These simple uncontinuing sounds are the result of few waves, there being no cause for their continuance.

We have not room in this article for any discussion of the manner in which sounds are conveyed through other bodies besides air, for which see Vibration. Noises conveyed through solid bodies travel generally quicker and are heard better; the scratch of a pin may be distinctly perceived through a long spar of wood, though inaudible by the person who makes it. With regard to gases, both theory and experiment agree in enabling us to assert, that any two of the same pressure and temperature, (that is, in which the barometer and thermometer would stand at the same height,) convey sound with velocities which are inversely as their densities. Thus, air being about thirteen times as heavy as hydrogen, the velocity of propagation in the latter is about thirteen times that in the former. Such a result cannot be directly submitted to experiment; but, as we shall see in the article Pipe, there are methods equally certain for ascertaining the truth.

The velocity of sound had been determined by experiment before the time of Newton, who gave the first mathematical solution of the question, with the following result: that if the atmosphere, instead of decreasing in density as we ascend it, were all to be reduced to the density at the earth's surface, but to be so diminished in height, that the pressure at the earth's surface should not be altered, the velocity of propagation would be that acquired by a heavy body falling unresisted from half the height of this *homogeneous atmosphere*. This reasoning, however, gave the velocity nearly *one-sixth* too small; and the cause of the difference was afterwards supplied by the sagacity of Laplace. This we shall try to explain. We know that air and all gases resist compression, and will expand themselves if the pressure of the superincumbent atmosphere be removed. This tendency is what we mean by the *elastic force* of the air or gas. If we take a column of air reaching from the earth's surface to the top of the atmosphere, the elastic force at any one stratum is equal to the weight of the superincumbent column, since it balances that weight. Moreover, it is observed, that, *at the same temperatures*, the elastic forces of two different strata are as their *densities*, that is, for air of half the density of common air, the elastic force is only half as great, and so on. It is also observed that any increase of temperature increases the elastic force if the density remain the same, and also that compression always increases the temperature; and *vice versâ*. If, therefore, a vessel of air were pressed into half its dimensions, it would double its elastic force from the condensation, which would also receive a further addition from the increase of temperature. Again, if the same were rarefied into double its first dimensions, the elastic force would be halved by the rarefaction, and receive a further decrease from the diminution of temperature. The increase or decrease arising from temperature would not last long, since the altered mass would communicate heat to the surrounding bodies in the first case, and receive it from them in the second; but in calculating such instantaneous effects as the propagation of sound, it is evident they ought not to be neglected. The supposition on which Newton went was, that the elastic forces of two strata of air are always in the same proportion as their densities, which is not true, unless the temperatures are the same. We may also here remark, that an alteration in the *barometer* only, produces no alteration in the velocity of air; for, if the barometer rise, though the pressure of the air is increased, yet the density is increased in the same proportion; that is, the force which is to set each mass in motion receives no greater increase in proportion than the mass which is to be moved. But a rise in the thermometer, accompanied by no change in the barometer, increases the velocity of sound, for there is an increase in the elastic force, without any increase in the density. A very good measure of this velocity made near Paris in 1822, under the directions of the Academy of Sciences, gave 1118 feet per second at the temperature of 61° of Fahrenheit. Earlier experiments had given 1130 feet, which, if the French measure is assumed as accurate, represents the velocity at a somewhat higher temperature. The number which we have adopted, viz., 1125 feet per second, at 62° of Fahrenheit, is shown by Sir John Herschel, in his masterly treatise on 'Sound' in the *Encyclopædia Metropolitana*, to accord very nearly with the mean of the best experiments. Every increase or decrease of temperature of 1° of Fahrenheit, causes a corresponding increase or decrease of $1\frac{14}{100}$ of a foot in the velocity of sound, which gives about 1090 for the velocity when the air is at the freezing point. We may add, that in the present state of our knowledge of the manner in which the temperature and elastic force of the atmosphere are connected, observation and theory give results which differ from one another by about a hundredth part of the whole.

When the exciting cause of sound is continued, as for example, when a board is scratched with a pin, we have a continued sound, caused by the succession of waves which the ear receives, which waves we have no reason to believe are all of the same length. But whenever the exciting cause is one, the vibrations of which can be shown to be performed in exactly the same time, so that the waves caused by them are all of the same length, we perceive a sound which gives pleasure to the ear, and has the name of *harmonious* or *musical*. This, however, only happens when the vibrations are at least thirty in a second, or the wave of a sound at most about 38 feet long. This fact is so well established, that we may consider it as certain that the pleasure arising from musical sounds is a consequence of the perfectly equal times of the vibrations which produce them, and of its result, the equal lengths of the sonorous waves propagated from them through the atmosphere. This will not appear so extraordinary, if we consider the very delicate nature of our organ of hearing. A person of tolerable ear can distinguish between two sounds, which only differ in that the one is a consequence of 400 vibrations in a second, and the other of 405. We must therefore grant to the ear a much higher power of perception as to sounds than the eye has as to length or surface. Some increase of the perceptive power may arise from the very great number of vibrations, since a result in some degree corresponding is observed in vision. If we look at a large number of parallel lines ruled close together at equal distances, any little deviation from parallelism or equidistance is much more sensibly seen than when the number of lines is small. And even to the eye, any moderately rapid succession of objects of the same kind is much more pleasing when they follow at equal distances and periods of time.

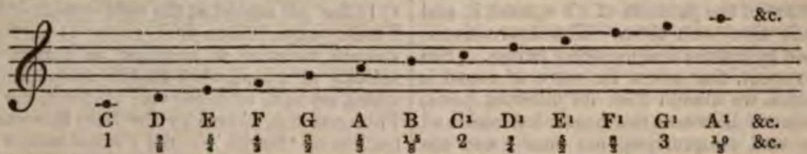
The difference between two musical sounds, which we express by saying that one is higher or lower than the other, is a consequence of the different number of vibrations performed by the two in the same time, and the sound which we call *higher* has the greater number of vibrations. And some sounds, when made together, produce an effect utterly unbearable, while others can be tolerated; others again are extremely pleasant, while some, though very different in pitch, appear so alike, that we call them the same, only higher. It is found by experiment that two sounds are more or less *consonant*, when heard together, according as the relation between their vibrations is more or less simple. Thus, when two vibrations of the first are made in one vibration of the second, (which is the simplest ratio possible, when the sounds are really different,) that similarity is observed to which we have just alluded; the first sound is called the octave of the second, and both are denoted in music by the same letter. When the number of vibrations of the two are as 3 to 2, the one which vibrates three times while the other vibrates two, is called a *fifth* above the other; because in the musical scale of notes



the vibrations of C and G are in this proportion, and G is the *fifth* sound reckoned from C. If the ratio of the vibrations be that of 3 to 4, that is, if the higher note makes four vibrations, while the lower note makes three, which is the case with C and its *fourth* F; or that of 4 to 5, which happens with C and its *third* E; the combined effect of the two is agreeable. The same may be said of C and its *sixth* A, in which the ratio is that of 3 to 5, or of E and its *minor sixth* (see MUSIC) C^1, in which the ratio is that of 5 to 8; or of E and its *minor third* G, in which the ratio is that of 5 to 6. We write underneath, the common musical scale in the treble clef, with the denominations of the notes and the fraction of a vibration which is completed, while the first C completes one vibration, which fraction is greater than unity, as the notes are rising. Thus while C vibrates once, D vibrates once and one-eighth; or 8 vibrations of C take place during 9 of those of D.

This is the musical scale pointed out by nature, since all nations have adopted it, or part of it at least. It fully verifies our assertion that the ear delights in the simplest combinations of vibrations. It would be hardly possible to place between 1 and 2, six increasing fractions where numerators and denominators should, on the whole, contain smaller numbers. We find, in the six intermediate fractions, only 2, 3, 4, and 5 singly, or multiplied by one another, no product exceeding 15. Neither has the whole of this scale always been adopted. It seems to have been formerly universal to reject F and B, the *fourth* and *seventh* of the scale; as is proved by the oldest national airs of the orientals, the northern nations, and even of the Italians. [See SCALE.]

Fig. 11.



&c.
C D E F G A B C¹ D¹ E¹ F¹ G¹ A¹ &c.
1 9/8 5/4 4/3 3/2 5/3 15/8 2 9/4 5/2 8/3 3 10/3 &c.

The following table will represent the proportions of the lengths of the sonorous waves which yield the preceding notes. These lengths decrease, as we have seen, as the *times* of vibration *decrease*, or as the numbers of vibrations in a given time increase.

Now, let two of these notes be sounded together, for example, C and G, in which two waves of C are equivalent to three of G. The resulting wave is, as we have seen in the preceding part of this article, twice as long as the wave of C, and the curve which represents the condensation and velocity of the particles of air is compounded, as before described, of those of the waves of C and G. The ear is able to perceive three distinct sounds, one of which is almost imperceptible, and indeed inaudible, unless carefully looked for. The two perceptible sounds are those of C and G from which the wave was made; nor are we well able to explain how this can be. Undoubtedly, if the curve, which is the type of the compound wave, were presented to a mathematician, he would be able, with consideration and measurement, to detect its elements; and to make that resolution which is done by the most unpractised ear. But we may, perhaps, assert that a savage, or a person totally unused to music, would not separate the sounds, but if C and G were sounded separately, and afterwards together, would imagine he had heard three distinct notes. The third sound, which is very faint indeed, is that belonging to the whole compound wave, which, being twice as long as the wave of C, belongs to the note called C, an octave below the first C of the preceding scale, which may be denoted by C$_1$. We may perhaps give an idea of this combination in the following way:—Let us suppose a series of equidistant balls to roll past us at the rate of two in a second, and another series at the rate of three in a second,—and let us moreover suppose that these balls roll in tubes placed one over the other, so that we only see each as it passes an open orifice in its tube, as in the figure.

Fig. 12.

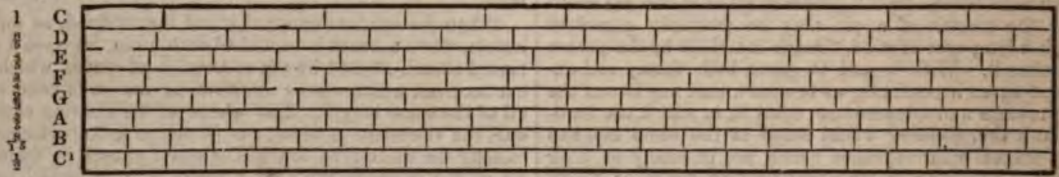


Fig. 13.

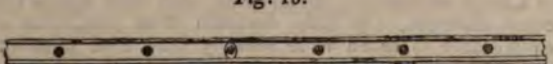


It is evident that we thus obtain three distinct successions: 1, that by which we might count 3 in a second from the lower tube; 2, that by which we might count 2 in a second from the upper tube; 3, that by which we might count single seconds, from observing when two balls pass together, and waiting till the same happens again. And we must recollect that any sound, however unmusical in itself, produces a musical note, if it be repeated regularly and often; so that it is not from the phenomenon itself, but from the frequency of its succession at equal intervals, that the pleasant sensation is derived. Thus in a passage, which has a strong echo, that is, where waves are reflected from wall to wall, as in the tube closed at both ends, already described, if the foot be struck against the ground, a faint musical note is heard immediately after the echo has ceased. By the action of the foot, shorter waves are excited, as well as the long wave, by the reflection of which the echo is caused. None of these would be repeated were it not for the reflection; but when the main sound is weakened by reflection, the shorter waves begin to produce the effect of a musical note, being, as we must suppose, less weakened than the longer wave. And we may here take occasion to observe, what will be further discussed in the articles PIPE and CHORD, that it is difficult to excite a perfectly simple wave, unaccompanied by shorter ones, which latter are always contained an exact number of times in the longer. Thus, if the note called C$_1$, or an octave below C in *fig.* 11, be struck on a piano-forte, the sounds G and E^1 (see the figure) will be distinctly heard as C becomes weaker, the waves of these notes being respectively one-third and one-fifth of those of C. When two notes are struck together, the effect is not pleasing, except when the numbers of waves per second in the two bear a very simple proportion.

We have noticed all the cases which the musicians call *concords*; the remainder, though contributing much to the effect of music, being called *discords*. Thus, if F and G be sounded together, in which (*fig.* 11) F makes $\frac{4}{3}$ of a vibration while G makes $\frac{3}{2}$, or F makes 8 vibrations while G makes 9, the effect is disagreeable, at least if continued for some time. On the piano-forte, in which the notes when struck subside into comparative weakness, this is not so much perceived; but on the organ, in which the notes are sustained, the effect is intolerable, and accompanied by an apparent shaking of the note, producing what are called *beats*, which we shall presently explain. Nevertheless, it becomes endurable, if not too long continued, provided F, the *discordant note*, as it is called, is allowed to pass to the nearest sound, which will make one of the more simple combinations of vibrations with G. The nearest such sound is E, which makes 5 vibrations, while G makes 6. For further information, we must here refer to the article HARMONY.

We now come to the absolute number of vibrations made by musical notes; all that we have said hitherto depending only upon the proportions which these numbers of vibrations have to one another; so that any sound might be called C, provided the sound produced by twice as many vibrations in a second were called C¹, and so on. We do not know that any measurements have lately been made in this country, but, from the Memoirs of the Academy of Berlin for 1823, it appears that the middle A of the treble clef, or the A in *fig.* 11, was produced by the following numbers of waves per second in the following different orchestras, showing a *small* variation between them, but one by no means insensible to the ear.

Theatre at Berlin - - - - - -	$437\frac{32}{100}$
Paris, French Opera - - - - -	$431\frac{34}{100}$
— Comic Opera - - - - -	$427\frac{61}{100}$
— Italian Opera - - - - -	$424\frac{17}{100}$

From this we may form an idea how many vibrations are necessary to create the sensation of a musical sound, and also at what point of the scale the vibrations per second would become so numerous that this effect should cease. If we take one of Broadwood's largest piano-fortes, and recollect that they are generally tuned (for private purposes) a little below the pitch of the orchestra, we shall not be far wrong in assuming that the A above-mentioned on these instruments is the effect of 420 vibrations per second. The lowest note, which is almost inappreciable (that is, though perfectly audible as a sound, yet hardly distinguishable from the notes nearest to it), is the fourth descending C from this A, and the highest is the third F above it, though the C above that, or the *fourth* ascending C from the A, can be well heard, and may be had by whistling into a very small key. We must however remark, that the point at which a series of undulations ceases to give a sound either from its slowness or rapidity, is different to different ears; sometimes so much so, that while one person complains of a note as too shrill, another cannot hear it at all. We write the above scale below, putting the A, whose vibrations we know, in its proper place,—

$C_3 \quad C_2 \quad C_1 \quad C \quad A \quad C^1 \quad C^2 \quad C^3 \quad C^4.$

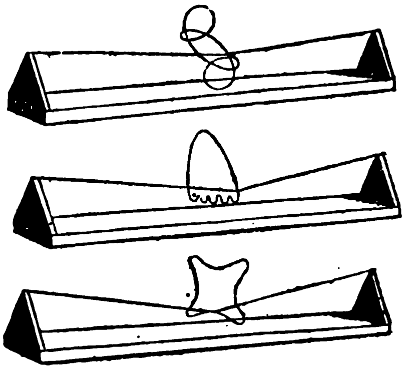
On looking at *fig.* 11, we see that A makes 5 vibrations while C makes 3; that is, A making 420 vibrations per second, C makes 252; therefore, C_1 makes the half of this, or 126; C_2 makes 63, and C_3 31½. Again, C¹ makes twice as many vibrations per second as C, or 504; C² makes 1008, C³ 2016, and C_4 4032 vibrations per second. That is to say, in round numbers, the ear receives a musical impression from any sound which arises from a number of vibrations between 30 and 2000; and we may certainly say that, in every orchestra, the hearers are employed in distinguishing and discriminating between various rates of succession in the undulations of the air around them from 60 to 2000 per second.

We have previously alluded to a phenomenon of sound, or rather of combined sounds, called a *beat*. If two notes whose vibrations are either nearly in the same ratio, or nearly in one of the simple ratios above-mentioned, be sounded together, the effect of their being out of tune is a tremulous motion of the sound, the pulsations or beats of which can be counted if the notes be not too high. For example, suppose two simultaneous notes whose vibrations are 100 and 104 per second. Here 25 vibrations of the first are made during 26 of the second; and the reader who has studied the preceding part of this article will see that the resulting wave is as long as twenty-six of the second waves; but that if the waves from the two be much alike in their types, this resulting wave will consist of a cycle of rarefactions and condensations very much resembling the separate waves. The whole resulting wave being twenty-six times as long as the second wave, will run through all its changes *four* times in a second, which is not sufficient to give a musical sound, but will only add to the sound of one of the waves the periodical tremulous sensation which is called a beat, which may be imitated by ringing the syllables *who*, *ah*, in rapid succession on the same note of the voice. For information as to the use made of these beats, see the article TEMPERAMENT.

It only remains to consider the different character of sounds. The same note, as to *pitch* or tone, may be sounded by a horn and a flute; nevertheless, each instrument has a character of its own, which enables every one to distinguish between the two. It is not to the different loudness of the two, for either, by skilful players, may be made to give the weaker sound; neither does it depend on the number of vibrations, for that, as we have seen, determines only the pitch of the note: the only difference between one wave and another of the same length, is in the *form* of its type; that is, in the different manner in which the air is condensed and rarefied. There is also only this feature left, to account for the difference between the tones which different players will draw out of the same instrument; since both Paganini and an itinerant street musician would make the same string vibrate the same number of times in a second. The late Dr. Young, to whom the world is much indebted on this subject, as on almost every other, examined the string of a violin when in motion, and by throwing a beam of light upon it, and marking the motion of the bright spot which it made, he found that the string rarely vibrated in the same plane, but that the middle point would describe various and very complicated curves, corresponding to different manners of drawing the bow. [*Lectures on Natural Philosophy*, vol. ii. plate 5.]

We give three specimens, merely to show how much the vibration produced by one player may differ from that of another. The waves proceeding from all three will be of the same length, the vibrations being performed in the same time; but the condensations and rarefactions will evidently be such as to give very different relative states to contiguous particles of air. The middle of the stretched wire describes the curve on which it is placed, during what we have hitherto called two vibrations.

Fig. 14.



It might tend to throw light upon this part of the subject if practical musicians would observe, in the same manner, the curves which they produce, and describe the different qualities of tone arising from them. As yet, we have no direct experiments which tend to connect any particular form of vibration with any particular quality of sound. We shall enter upon the best method of doing this in the article CHORD.

Some confusion arise in books on this subject, from the use which different authors make of the words *vibration* and *wave*. Some mean, by a vibration, a motion to and fro, which, in this article, we have called *two* vibrations; and by a wave, the complete succession of condensations and rarefactions, which we have called *two* waves, one of condensation, the other of rarefaction. For further information, we refer the reader to Sir J. Herschel's article, already cited, to Robison's *Mechanical Philosophy*, Biot's *Précis Elémentaire de Physique*, and Pouillet's *Traité de Physique*.

ACQUAPENDENTE, a town in the Roman States, near the confines of Tuscany, on the high road from Florence to Rome. (Lat. 42° 46′ E., long. 11° 52′.) The name is derived from the fall of water from the rock on which it stands. It is built on a steep hill which rises above the river Paglia, and is surrounded by walls. Girolamo Fabrizio, a celebrated anatomist and professor at Padua in the sixteenth century, was a native of this town. It was but an insignificant place until 1650, when Pope Innocent X. having razed to the ground the neighbouring town of Castro, where a bishop had been murdered, transferred the see to

Acquapendente. The town looks ill-built and dull: it belongs to the delegation or province of Viterbo, and is seventy miles N.N.W. of Rome. It contains a cathedral, and about 2400 inhabitants.

ACQUITTAL (from the French *acquitter*, to free or discharge) signifies a deliverance and setting free of a person from a charge of guilt; thus a man who, upon his trial for a criminal offence, is discharged by the jury, is said to be acquitted. The acquittal by the jury has, however, no force in law until judgment has been given upon the verdict by the court in which the proceedings are instituted.

After judgment of acquittal, if the party be indicted a second time for the same offence, he may plead his former acquittal as a bar or a complete answer to the second charge, and upon such former acquittal being admitted or proved, the person indicted will be entitled to be discharged, as the law will not permit a man to be twice put in danger of punishment for the same offence.

ACQUITTANCE is a discharge in writing of a debt, or sum of money due. A general receipt or acquittance in full of all demands will discharge all debts, except such as are secured by what are termed *specialties*, viz., bonds and instruments under seal; which are considered by the law as of too great force to be discharged by a verbal concord and agreement, or any less formal and solemn acquittance than a deed. Where an acknowledgment of satisfaction is by deed, it may operate as a good answer to an action on the debt, even though nothing has ever been actually received.

Courts of equity, and even courts of law, will, in some cases, order accounts to be gone into anew, notwithstanding the production of a general acquittance or receipt in full of all demands, upon proof that such acquittance was obtained by fraud or given under a mistake, and that the debt or other demand has not been in fact satisfied.

ACRE, a measure of land, of different value in the different parts of the United Kingdom. When mentioned generally, the statute or English acre is to be understood. Its magnitude may be best referred to that of the square yard by recollecting that a square whose side is 22 yards long is the *tenth* part of an acre; whence the latter contains 22×22×10, or 4840 square yards. The chain with which land is measured is 22 yards long; so that *ten* square chains are one acre. This measure is divided into 4 roods, each rood into 40 perches, so that each perch contains 30¼ square yards. Thus:—

Acre.		Rood.		Perch.		Square yards.	Side of equivalent squares in yards.
1	=	4	=	160	=	4840	69.5701
		1	=	40	=	1210	34.7851
				1	=	30¼	5.5

The Irish acre is larger than the English, inasmuch as 100 Irish acres are very nearly equivalent to 162 English acres. More correctly, 121 Irish acres are 196 Englis hacres; but the former ratio points out an easier arithmetical operation, and will not be wrong by so much as one acre out of 5000.

The Scottish acre is also larger than the English, 48 Scottish acres being equal to 61 English acres. There are also local acres in various parts of England, such as the Cheshire acre of 8 yards to the pole. The English statute acre is used in the United States of North America.

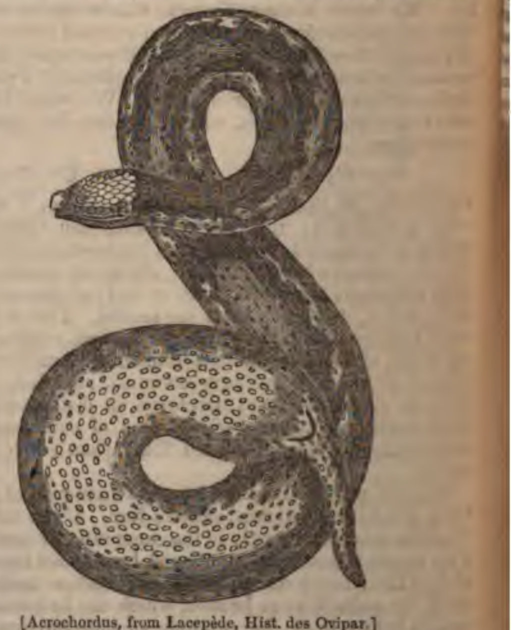
The French *Are* is a square whose side is 10 metres, and 1000 English acres are equivalent to 40,466 ares.

For further information on the comparison of English and other acres, we refer the reader to Kelly's *Cambist*, a very useful work.

ACRE (ST. JEAN D'), a town of Syria on the seacoast (N. lat. 32° 54′, E. long. 35° 4′), and on a small promontory, which, with Mount Carmel lying to the south, forms a circular bay: it is sometimes called Acra and Acca. Its oldest name was probably Acco, which was changed to that of Ptolemais during the sovereignty of the Greeks in Syria: the name of Acco was revived after it fell into the hands of the Saracens. Acre is well known in the history of the Crusades, having been taken in 1191 by Philip Augustus of France and Richard I. of England. It was for some time in the possession of the Knights of Malta, during whose occupation it was strongly fortified, and filled with churches. Acre was in a very ruinous condition in the middle of the seventeenth century, when Thevenot visited it, but it has since been improved, and is now said to contain 15,000 (some authorities say 20,000) inhabitants. This restoration was due to Sheik Daher, who, in the middle of the eighteenth century, strengthened the town and revived its commerce. Jezzar Pasha, his successor, fortified the place very strongly, and built a new mosque, according to Turkish fashion adorning it with columns that once belonged to the old Greek edifices of neighbouring cities. The streets of Acre are narrow, and the houses, which are of stone, have flat roofs. The port is small and not deep, yet it is one of the best along this coast. Europeans carry to Acre cloth, lead, tin, &c., and receive in exchange some cotton and rice. The great celebrity of Acre, in more recent times, is owing to Bonaparte's attempt to storm the place in the spring of 1799, when he entered Syria at the head of 12,500 men. The obstinate defence of the garrison commanded by Jezzar, and aided by Sir Sidney Smith with English sailors, saved Acre from the repeated assaults of the French general, who, after spending more than sixty days before it, and losing near 3000 men, retreated to Egypt. Since the siege in 1799 the fortifications have been repaired, but, in the last year (1832), Acre has had to withstand another siege, and is at present in the hands of the Pasha of Egypt, who took it from the Sultan of Constantinople, his master, on the 2d of July.

Acre is also the name of one of the Syrian pashalicks, which in late years has been bounded to the north by that of Tripoli, to the south and east by the pashalick of Damascus, and on the west by the Mediterranean. Its chief ports are Acre and Beirout. We propose to describe the whole country under the more permanent and general name of SYRIA.

ACROCHO'RDUS (a word formed from the Greek, which signifies *a wart*), in Zoology, a genus of serpents discovered in Java by the traveller Homstedt, and described in the *Memoirs of the Stockholm Academy of Sciences* for 1787. This genus is easily distinguished from others of the innoxious family of serpents by the innumerable small scales which cover every part of the head and body both above and below, and which in preserved specimens, or when the live animal distends the lungs and body with air, assume the appearance of so many granulated warts or tubercles. This circumstance has suggested the name of acrochordus, which conveys a pretty accurate idea of the external covering of the animal described by Homstedt.



[Acrochordus, from Lacepède, Hist. des Ovipar.]

The acrochord, in fact, is covered with scales like all other serpents, though they are minute and separate from one another: each of them is marked with three small ridges, and it is only when the skin is inflated, and apparent between the scales, that these assume the granulated or warty appearance expressed by the name. The head of the acrochord is flat, the mouth provided with a double row of small, sharp teeth, but without poison fangs, and the throat capable of enormous dilatation. Though deprived of the ordinary apparatus by which venomous serpents convey their poison, zoologists are not yet agreed in considering the achrocord as altogether innocent. MM. Appel and De Blainville affirm that they have found a peculiar bone in the head of this serpent, which they conceive to supply the place of the poison fang: Cuvier, on the other hand, denies the existence of this bone altogether, and brings forward the testimony of M. Leschenhault in favour of the harmless nature of the acrochord; and as the latter gentleman travelled for some time in Java, and made various experiments upon the live animals, for the purpose of ascertaining this point, there seems to be no reason to doubt the truth of his report. The tongue of the acrochord is short and thick, the vent simple and without the horny spurs which are common to many other genera of serpents. The only species sufficiently known at present is

The *Oular Carron* of the Javanese, the *Acrochordus Javanicus* of Lacepède and others. The scales of this serpent are marked by three small carinated elevations; the body is black above, greyish-white beneath, and the sides are marked with black spots on a ground of the same colour as the belly. The head is covered with small scales, the mouth is contracted, and the under jaw shorter and broader than the upper. This animal averages from six to eight or ten feet in length, and its shape is altogether peculiar; the body does not gradually become thinner from the middle towards either extremity, as in the generality of serpents, but grows gradually thicker from the head to the vent, and there suddenly contracts, so as to form a very short, slender tail. In the thickest part of the body, immediately above its junction with the tail, the individual procured by Homstedt, of which the entire length was eight feet three inches, measured three inches in diameter, whilst the greatest breadth of the tail did not exceed half an inch, and its length was scarcely a ninth part of that of the whole body. This individual was a female, and, when opened, was found to contain five young ones perfectly formed, and about nine inches in length. It was caught in a plantation of pepper-trees, and the Chinese, who accompanied Homstedt, cooked and ate its flesh, and reported it to be of a most delicious flavour. The stomach contained a quantity of half-digested fruit, from which it has been inferred that this serpent is frugivorous, and, contrary to the habit of all other known species, feeds upon vegetable substances. Cuvier is incredulous upon this point: it is certainly a singular circumstance, and should be received with caution; but, on the other hand, we have no reason to doubt the testimony of Homstedt; and the mere singularity of the fact does not necessarily destroy its probability. We know, moreover, that tortoises, turtles, some genera of fishes, and even certain species of lizards,—all of them cold-blooded animals, and some approaching very nearly, in nature and organization, to the family of serpents to which the acrochord belongs,—live entirely upon vegetable food; and the knowledge of this fact ought to prepare us beforehand to expect the discovery of similar habits among certain tribes of serpents, rather than to reject them as impossible and as absurd fictions.

ACRO'NYCHAL (sometimes incorrectly written Acronical, and Achronical), a word derived from the Greek, signifying 'that which determines the extremities, or the beginning and end, of the night.' It is only used in reference to the rising or setting of the stars; and a star is acronychal or rises acronychally when it rises at or very near sunset, and consequently sets at or near sunrise. To determine what stars rise acronychally on any given night, elevate the pole of a common globe so that the arc intercepted between it and the horizon may be equal to the latitude of the place. Turn the globe until the sun's place is on the horizon at the *western* side, then will all stars which are either on or within a short distance of the horizon on the *eastern* side be acronychal.

ACRO'POLIS, a Greek compound word signifying 'the highest point of a city.' It was used to denote some hill, rock, or natural elevation, such as we find forming part of the sites of many ancient cities in Greece. It seems natural to conclude that such strong holds were among the places first occupied, and that they served as the kernel of a larger city. In course of time, when building spread, such eminences became strong posts analogous to castles or citadels in modern cities; and in many instances the possession of such posts was considered as equivalent to the possession of the cities themselves. Religious edifices also generally formed part of the structures of an Acropolis.

In modern times they have often served as places of refuge to the inhabitants from the attacks of an enemy, or from the incursions of corsairs. The term Acropolis is now most commonly applied to the rocky eminence of Athens, on which the remains of the Parthenon or Temple of Minerva stand; but this is only a limited use of the word. Corinth had an Acropolis called Acro-Corinthus, which is a much loftier and more commanding eminence than that of Athens. The view from the summit is extensive, and the temple on the Acropolis of Athens, nearly fifty miles distant, is distinctly seen. An eminence close upon the modern Argos in the Peloponnesus was the Acropolis of the ancient Argos, and then it was called Larissa. A ruined castle of comparatively modern construction occupies the summit of this rocky eminence, and shows in some parts traces of much earlier building. The Acropolis of Messene in the Morea, situated on Mount Ithome, is another remarkable specimen of these natural bulwarks which were once fortified according to the principles of Greek military science. [See Leake's *Morea*, 3 vols. 8vo.—Society's Plan of Athens.]

ACROSTIC, a Greek term, signifying literally the beginning of a line or verse. An acrostic is a number of verses so contrived that the first letters of each being read in the order in which they stand shall form some name or other word. According to some authorities, a writer named Porphyrius Optatianus, who flourished in the fourth century, has the credit of being the inventor of the acrostic. It is probably, however, of older date. Eusebius, the bishop of Cæsarea, who died in A.D. 340, gives in his Life of Constantine, a copy of Greek verses which he asserts to be the composition of the Erythræan Sibyl, the initial letters of which make up the words ΙΗΣΟΥΣ ΧΡΙΣΤΟΣ ΘΕΟΥ ΥΙΟΣ ΣΩΤΗΡ, that is, Jesus Christ, the Son of God, the Saviour. These verses, which are a description of the coming of the day of judgment, have also been translated into Latin hexameters so as to preserve the acrostic in that language, in the words Jesus Christus Dei Filius Servator. The translation, however, wants one of the wonderful qualities of the original; for it will be observed that the initial letters of the five Greek words being joined together, form the word ΙΧΘΥΣ, that is, *the fish*, which St. Augustine, who quotes the verses in his work entitled *De Civitate Dei*, informs us is to be understood as a mystical epithet of our Saviour, who lived in this abyss of mortality without contracting sin, in like manner as a fish exists in the midst of the sea without acquiring any flavour of salt from the salt water. This may be therefore called an acrostic within an acrostic. But there are also other ways of complicating these ingenious productions. Addison, who notices this along with other sorts of false wit, in his lively papers on that subject in the first volume of the *Spectator*, says, 'there are *compound* acrostics, where the principal letters stand two or three deep. I have seen some of them, where the verses have not only been edged by a name at each extremity, but have had the same name running down like a seam through the middle of the poem.' There are even instances of the same name being five times repeated in so many successive columns. Such an acrostic has been designated a *pentacrostic*. This species of elaborate trifling was extremely fashionable among the early French poets, from the age of Francis I. down to that of Louis XIV. Some also of our English poets of considerable eminence used formerly to amuse themselves in the same way. Thus, for instance, among the works of Sir John Davies, are twenty-six short poems entitled *Hymns to Astræa*, each of which is an acrostic on the words *Elizabetha Regina*. These, which were first published about the end of the sixteenth century, are perhaps the most elegant compositions of this description in any language. Afterwards such puerile ingenuity fell into disrepute; and Dryden, in his *Macflecknoe* (published 1682), contemptuously makes the dying monarch of the realms of nonsense and dulness address his son and successor Shadwell:—

> 'Leave writing plays, and choose for thy command
> Some peaceful province in acrostic land.'

The acrostic, being addressed merely to the eye, and conveying no pleasure either to the imagination or to the ear, cannot of course add to the poetical effect of the lines which it ornaments—any more than would the printing of the initial letters in a differently coloured ink. But it is sometimes useful, as an aid to the memory, in recollecting such verses as are composed only to be got by heart, for the sake of the facts of which they form a summary. Thus, in some editions of the Latin dramatist Plautus, we find prefixed to each play a few verses which contain at the same time an acrostic on its name and a sketch of the plot. In this case, the knowledge of the initial letter of each line must help the memory to recover it, if it should be forgotten. There are two epigrams in the Greek Anthology, one in honour of Bacchus and the other of Apollo, which are called acrostics, though of a somewhat peculiar fashion. Each contains twenty five verses, of which the first introduces the subject of the poem, and each of the twenty-four others consists of four words, which are epithets of the god: all the epithets in the first line begin with A. those in the second with B, and so on. These poems, therefore, are merely acrostics on the alphabet, four deep. The Jews sometimes employ a sort of acrostic in designating many of their writers. Thus the commentator on *Maimonides*, Rabbi Yom Tof bar Abraham, is commonly called Ritba. from the initial letters of the five words composing his full title. (See this explained in the article entitled 'Literary Chronology,' in the *Companion to the Almanac* for 1832.) The initial syllables of the verses of the Psalms were anciently called acrostics. The following is a curious specimen of a Latin acrostic:—

S A T O R
A R E P O
T E N E T
O P E R A
R O T A S

ACROTE'RION (in Architecture), a Greek term, signifying 'the extremity of anything.' It is used technically to designate the statue or other ornament on the summit or upper angle, and is sometimes applied also to the similar ornaments over the feet, or lower angles, of a pediment; in the latter case they are all included under the plural *acroteria*. Some writers understand by this term only the bases or pedestals on which the acroterial ornaments are placed; for this restriction, however, there is no good reason, but rather the contrary, as it would leave the ornaments themselves without an appropriate designation. It may, indeed, with great propriety be used much more extensively than has been the custom. The *finial* on the apex of a spire, pinnacle, or gable, in works of pointed architecture, is an acroterion; and in St. Paul's Cathedral in London, although the pediments over the entrance fronts have their acroteria, which are statues of some of the Apostles, yet the acroterion of the edifice is the cross which surmounts the grand central part of the composition. This term is not found in many ancient authors; we derive it from Vitruvius, who uses it in the plural sense abovementioned. Plutarch, in his life of Cæsar, makes use of it in the singular number, and in the purely architectural sense as we have rendered it.

ACT OF PARLIAMENT.—See Statute.

ACT (in the Universities). An exercise to be performed by students before they are admitted to their degrees. In the University of Oxford it has almost fallen into disuse, and in Dublin is a mere form; but at Cambridge it is still preserved as a preliminary test of the comparative merits of the candidates for the degree of Bachelor of Arts, who aspire to University honours. It is also performed by candidates for the degrees in law, physic, or divinity. The student proposes certain questions connected with his subject to the presiding officer of the *schools* (the place in which acts are kept), who thereupon nominates other students to oppose them. The discussion is carried on syllogistically and in Latin, and terminates by the presiding officer questioning the *respondent* or the person who is said to 'keep the act,' and his *opponents*, and dismissing them with a short compliment to each, in proportion to his deserts.

The severest exercise of this kind being that undergone by candidates for the degree of Bachelor of Arts, with *honours*, at Cambridge, we will describe it more particularly. The *moderator*, or examiner for the year, gives notice to a student that he is to keep an act; who thereupon writes three questions which he proposes to maintain and defend. The first is always from Newton's *Principia;* the second from any other mathematical subject; and the third from some metaphysical or moral writer. The following is an example of the form in which they are given:—

Rectè statuit Newtonus in Sectione primâ libri primi.

Rectè statuit Lagrangius in capite primo libri de theoria functionum.

Rectè statuit Lockius de principiis innatis.

The above signifies that the student intends to maintain the correctness of the first section of Newton's *Principia*, the first chapter of Lagrange's *Theory of Functions*, and the chapter of Locke on the *Human Understanding* which treats of innate principles.

The moderator, on receiving these, nominates three students, whose attainments, he thinks, will enable them to propose arguments on the other side. On the day appointed, the moderator having taken his chair, the *respondent* reads a Latin thesis, usually on the third subject; after which the opponents, in succession, propose their arguments against the several subjects, which, of course, are usually ingenious fallacies. If the respondent can answer them, he does so; if not, the moderator endeavours, by questioning him, to find from what defect in his knowledge of the subject this arises. As each opponent is dismissed he is also questioned by the moderator, as above stated.

The syllogistic form is not strictly retained at present in keeping an act; and the Latin spoken is very indifferent. The chief purpose of an act now-a-days is to get a sort of notion of the qualifications of the candidates, as the examination is proportioned in severity to their supposed capacities. In older times an act was a very important feature in obtaining a degree. The utility of the present form is doubted by many persons.

ACT (in the Drama.) That portion of a play, which is separated from the rest by an interval, during which the stage is left empty, and the action is supposed to proceed unseen by the spectators. In the Greek drama there were no acts; although in some modern editions, such as Burton's *Pentalogia*, we find Greek plays thus divided. The language does not possess a word answering to the Latin and English *Act*. Among the Greeks the stage was never left empty from the beginning to the end of the performance; when the other actors retired, those forming the chorus still remained, and continued the business of the play by their songs. For these songs, it is important to observe, were in general essential parts of the drama; they were not of the nature of a piece of music, or a dance, or any other extrinsic representation, thrown in merely to fill up a chasm in the action; they carried forward the action in the same manner as the ordinary dialogue did. For an exact copy of the form of a Greek drama in this respect, the English reader may be referred to the *Sampson Agonistes* of Milton. In that play there is no division into acts; nor is there any such division in Buchanan's two Latin tragedies, entitled *Jephthes* and *Baptistes*, which are also professedly composed upon the Greek model. The latter poet, we may add, has followed the same plan in his translations of the Medea and the Alcestis of Euripides. From this constitution of the Greek drama, it naturally followed, that the real duration of the action of any play could not well be supposed greatly to exceed that of its theatrical representation. In other words, what has been called the Unity of Time became a principle almost invariably observed in every dramatic composition. On the Roman stage there was no chorus, and the play was divided into acts, as on our own. But, although Plautus has frequently in his comedies supposed a considerable portion of time to pass between the close of one act and the opening of another, the most famous of the Latin dramatists, Terence, has not availed himself of this liberty, but has adhered closely to the practice of his Grecian models, in not permitting the interval between the acts to form more than a very short interruption of the progress of the story. By modern dramatists, however, the practice of dividing a play into acts has generally been taken advantage of to extend the time of the story greatly beyond the space to which it was necessary to confine it on the Greek stage. Each act, in fact, is now what the Greeks would have called a separate drama, except that it does not contain a complete plot; and the whole play may be compared to those Trilogies of the Greeks, in which three dramas, representing so many successive separate parts of the same history, followed one another in one theatrical exhibition. Perhaps it was this consideration which made the Romans call each of the separate portions in question an *Act* or *Actus;* for that word is exactly a translation of the Greek *δρᾶμα*, which was used to designate an entire play. The term, therefore, may be taken as in its original and proper sense, denoting a distinct, and, to a certain extent, independent theatrical action or picture, although capable also of being introduced as one of a series of such pictures, united by some common subject. And this is precisely what Shakspeare must be understood to mean, when, in the famous speech which he puts into the mouth of Jaques in *As you like it*, comparing the world to a stage, he goes on to say, 'One man in his time plays many parts, his *acts* being seven ages.' The infant, the school-boy, &c., are *acts*, only in the sense of being so many separate pictures or exhibitions of human life, each complete in itself, although following each other according to a natural order of succession, like the acts of a play. Viewed in this light, it will be perceived, that the division into acts, is really that distinction of the modern drama which more than anything else gives to it its peculiar character. Dr. Johnson has observed, in modern plays, 'The time required by the fable elapses, for the most part, between the acts; for of so much of the action as is represented, the real and poetical duration is the same. . . . . . The drama exhibits successive imitations of successive actions; and why may not the second imitation represent an action that happened years after the first, if it be so connected with it, that nothing but time can be supposed to intervene. Time is, of all modes of existence, most obsequious to the imagination; a lapse of years is as easily conceived as a lapse of hours.'—*Pref. to Shakspeare.*

We may here remark, that although the French dramatic writers have adhered to the principle of leaving the stage empty only at the end of an act, many of the English have followed a different practice. In Shakspeare particularly, every successive scene uniformly presents a new set of characters, and most commonly a change of place also. He rarely interrupts the action, however, for any considerable space, except during the interval between two acts; but here he does not hesitate to pass over any length of time he may find convenient. In the *Winter's Tale*, Perdita, who who was a new-born infant at the end of the third act, is grown-up a young woman at the beginning of the fourth. In this instance, indeed, the dramatist introduces Time to explain and apologize for the licence he had taken to

> ———— 'Slide
> O'er sixteen years, and leave the growth untried
> Of that wide gap.'

Time is here said to appear 'as Chorus;' and in the beginning of Henry V., Chorus is also brought forward to request the audience to allow their thoughts in the course of the representation to pass from one place to another—

> ———— 'Jumping o'er times;
> Turning the accomplishment of many years
> Into an hour-glass.'

Neither of these personages, however, performs exactly the office of the ancient chorus.

We may add, that the old English Mysteries and Moralities, the first produce of our national dramatic genius, were long destitute of any division either into scenes or acts. This is the case, for instance, with Parfre's Mystery entitled *Candlemas Day, or the Killing of the Children of Israel*, written in 1512, and first printed in Hawkins's *Origin of the English Drama.* In this performance there are not even any stage-directions. The Morality of *Every Man*, printed early in the reign of Henry VIII., and that of *Hycke Scorner* of the same age, are, in like manner, without either stage-directions or any division into acts or scenes. In the Morality of *Lusty Juventus*, again, which was published in the reign of Edward VI., there are stage-directions, but still no mention of acts or scenes. The earliest of the Moralities which assume the regular dramatic shape are not more ancient than the beginning of the reign of Elizabeth. Moralities continued to be both printed and acted long after this date. We may mention, among others which appeared after Elizabeth came to the throne, Skelton's *Life and Repentance of Mary Magdalene*, 1567; *The Marriage of Wit and Science*, 1570; *The Conflict of Conscience*, 1581; *The Three Lords of London*, 1590; &c. Even Mysteries were performed in the reign of Mary. Nay the Chester Mysteries were performed in the year 1574. Down to this time there is every reason to believe that the scene never was changed from the beginning to the end of any stage-spectacle. As for the Moralities, they were acted even in the reign of James I., and they are enumerated under the name of 'Morals' in the licence granted to the company of which Shakspeare was a member in 1603. But even several of our early tragedies and comedies, down to an era subsequent to this, were without any division into either scenes or acts. There is no such division in Preston's *Cambises*, the play to which Shakspeare is supposed to allude in *Henry V.*, and which the author entitles *A lamentable Tragedy mixed full of pleasant Mirth*, printed in 1561; nor in Peele's *David and Bethsabe*, which appeared in 1579. In the tragedy of *Soliman and Perseda*, 1599 (supposed to be by Kyd), there are acts, but not scenes; but there are neither one nor other in Dekker's *Satiromastix, or the Trussing of the Humorous Poet*, nor in the comedy of the *Wily Beguiled*, both of which appeared after the commencement of the seventeenth century, the latter so late as 1623.

Much discussion has taken place among the critics on the reasons of the rule which restricts a regular dramatic composition to the extent of neither more nor less than five acts; and which Horace, in his Art of Poetry, has laid down in a peremptory and well-known verse. Upon this subject the French writer, Marmontel, has delivered a very sensible judgment:—'The established usage of distributing a tragedy into five acts, neither stands upon such a foundation as to constitute it an essential law, nor is it so unreasonable as to deserve to be banished from the theatre. When the subject is such as to furnish that number, five acts allow a desirable extension to the action; in that space great events find room; great interests and great characters have freedom to develop themselves; the situations lead in each other; one incident announces the next; the sentiments are introduced without bluntness or harsh collision; the movement of the passions has time to attain the requisite acceleration, and the interest to grow to the highest degree of pathos and intensity. It has been found by experience that the attention, the illusion, and the emotion, which a spectacle of this duration excites, are not too great for the audience. * * * But the subject may be naturally such, as, not affording room for more than two or three points of repose, not to be susceptible of more than the same number of situations striking enough to form successive steps in the action. Must the subject in that case be abandoned, although pathetic, interesting, and teeming with beauties? or must it be overlaid with scenes and incidents that do not properly belong to it? By no means. The action must have its just extent given to it, and no more. The law of nature must be followed, which is superior to that of art.'—[*Encyclopédie*, Art. *Acte.*]

ACT of FAITH.—[See Auto da Fe′.]

ACTA DIURNA (proceedings of the day) was the title of a gazette, to use the nearest modern term, drawn up and published daily at Rome both under the republic and the empire. It appears to have contained an abstract of the proceedings of the public assemblies, of the law courts, of the punishment of offenders, an account of any public buildings or other works in progress, together with a list of births, deaths, marriages, and divorces, &c. In the very earliest times of Rome provision was made under a religious sanction for the due registration of birth, assumption of the *toga virilis* (or dress of manhood), and death, accompanied by the payment of a certain fee into the respective treasuries of the goddesses *Juno Lucina*, *Juventas*, and *Venus Libitina.* From the registers thus formed such extracts as were important might be made for publication. The law courts would furnish authority for the statement of divorces; and in this article of news there was no deficiency. Not a gazette appears, says Seneca, without its divorce, so that our matrons, from constantly hearing of them, soon learn to follow the example. The due supply of information on political and judicial affairs was to be obtained, as now, by reporters (*actuarii*). In the celebrated debate of the Roman Senate, upon the punishment of those who had been concerned in the Catilinarian Conspiracy, we find the first mention of short-hand writers, who were specially employed by Cicero to take down the speech of his friend Cato; and it is interesting to observe that this was the only speech of that extraordinary man which still existed in the age of Plutarch. But it must not be inferred from this fact, that these reporters or any other persons were at liberty to publish an account of any proceedings in the senate. Until the first consulship of Julius Cæsar the senate was a close court. This great man, by a ludicrously distorted view of Roman history, has been generally represented as the destroyer of his country's liberties, and he was doubtless prompted by motives of personal ambition; yet he no sooner entered upon his office than he made provision for giving the same publicity to all the proceedings of the senate which already existed for the more popular assemblies; and this single act was, perhaps, the most fatal blow which Cæsar gave to the aristocratic interest. [Suetonius, *Life of J. Cæsar*, c. 20.] Under the despotism of Augustus such an institution was inconvenient, and, therefore, repealed. The *Acta* of the senate, though, of course, still registered, were no longer published; and, as all the popular assemblies were now deprived of real authority, the *Acta Diurna* henceforward can have had little political interest. Even in its best days this state gazette was, no doubt, an extremely meagre document,—conducted as it was on government authority, without the advantages of competition, and what is still more important, without the possibility of extensive circulation; for what could a newspaper have been before the art of printing was discovered? Yet, with all these disadvantages, the *Acta Diurna* were often consulted and appealed to by the historians of after times, as documents of the highest authority. [For a more minute account, see Lipsius in his *Excursus* on the Annals of Tacitus. Lib. v. c. 4.]

ACTA ERUDITO'RUM, the title of one of the oldest and most celebrated literary and scientific journals. It began to be published at Leipzig in January 1682, under the conduct of the learned Otto Mencke, one of the professors of the university, assisted by several of his brother professors, and especially by Carpzov (Morhof, *Polyhistor*, i. 178. edit. 1747). The numbers, which were in 4to., appeared once a month. On the death of its original editor in the beginning of the year 1707, the management of the journal was undertaken by his son John Burchard Mencke; on whose death, in 1732, the charge devolved on his son Frederic Otto. The property of the work seems to have remained to the last in the hands of the Mencke family, or their heirs; but the latter editors were not men of distinguished name. The last was Charles Andrew Bel, professor of philosophy in the university, who, after managing the publication from 1754, died on the 4th of April, 1782. The volume for 1776, was only published in that same month. It was the last which appeared; although the publisher intimates his hope that the work will regain its ancient reputation, having thus got rid of the editor who had allowed it to fall so sadly into arrear, a matter, he remarks, concerning which the less that is said the better. The Acta Eruditorum was the first critical journal published in Latin; and it did not confine itself merely to reviews of books, but inserted also accounts of scientific discoveries, and of the general progress of mathematical and physical science. It was here that Leibnitz, who was a frequent contributor in the early period of the work, first announced his method of the differential calculus. In the hands of its early editors, it was considered to be admirably conducted; and Morhof congratulates his countrymen on having, in this publication, produced something which even commanded the approbation of foreigners, 'who rarely,' he is pleased to add, 'find anything done by us (the Germans) to their taste.' He mentions a translation of the Acta into French, which had been undertaken; but this undertaking does not appear to have proceeded beyond the first volume, which was published in 12mo. at the Hague in 1685, under the title of *Ouvrages des Savans, publiéz à Leipzig*. After the first fifty volumes, coming down to the end of the year 1731, the journal took the name of the *Nova Acta*, or the New Acts. The first series, besides the fifty regular volumes, consists of ten supplementary volumes, one having been published every five years. Occasional supplements also appeared in the course of the new series; which, together with several volumes of Indices, make the complete work amount to 117 volumes.

Many other journals established in imitation of that of Leipzig also assumed the name of Acta; as, for instance, the *Deutsche* (or German) *Acta Eruditorum*, begun to be published in 8vo., at Leipzig, in 1712, and which was continued till 1740, the whole forming 20 volumes; the *Fränkische Acta Erudita et Curiosa*, a journal of French literature, published at Nuremberg, from 1726 till 1732; the *Deutsche Acta Literaria*, which began at Leipzig in 1715, but did not last above a year or two; &c. Under this head also we may notice the English journal, entitled the *History of the Works of the Learned*, of which the first monthly number appeared at London, in small 4to., in January 1699, and of which 13 volumes were published under that title, when it was discontinued at the end of the year 1711. The same title, however, was again adopted in 1737, by a periodical work which first appeared in 1735, under the name of the *Literary Magazine*, or *Select British Librarian*. It continued to flourish under its new designation till the year 1743, when it closed with the publication of its 14th volume. This publication is not to be confounded with another critical journal which appeared at London in 4to., in 1691, under the title of *The Works of the Learned*, by J. la Crose, a late editor of the *Universal Bibliotheque*. It continued only for a few years. The *Universal Bibliotheque* was an English translation, which was published for a short time, of Le Clerc's *Bibliothèque Universelle*, begun at Amsterdam in 1686. There was also a work called an *Historical Account of Books and Transactions of the Learned World*, which began to be published at Edinburgh in 12mo., in 1688. [See Watt's *Bibliotheca Brit.*] The title Acta has also sometimes been given to the published Memoirs or Transactions of Learned Societies.—[See ACADEMY, and SOCIETY.]

ACTÆ'A. Under the name of ἀκτῆ, the Greeks described a medicinal plant, which the moderns have ascertained to be what is now called *Sambucus ebulus*. [See SAMBUCUS.] Linnæus applied the name to a genus of perennial herbaceous plants found in various parts of Europe and the north of Asia, and America, belonging to the natural order Ranunculaceæ, and only in a slight degree resembling the species intended by classical authors. The genus thus understood is known from all others of the Ranunculus tribe by its anthers being turned inwards, so that when they burst, the pollen may immediately fall upon the stigma, while its flowers have only four sepals and four petals. All the species have their leaves in many broad divisions, and their blossoms arranged in tall, branched panicles; these are followed by little fleshy, berry-like fruits, of a black, or white, or red colour. The properties of all the species are nauseous and deleterious, as might be expected from their affinity to the poisonous Aconite.

One species, *Actæa spicata*, a common European plant, is found occasionally in the north of Yorkshire among bushes; it is popularly called Black baneberries and also Herb Christopher. It has purplish-black juicy fruits, which would be dangerous from their tempting appearance, if the fetid odour of the leaves did not prevent their being touched.

Another species, the *A. cimicifuga*, a North American plant, derives its name from the belief that its fetid leaves have the power of driving away bugs.

ACTI'NIA, a genus of animals belonging to the sea nettles (*Acalephæ*, Cuvier), and distinguished by the form of their body, which is simple, cylindrical, soft, fleshy, and susceptible of contraction and dilatation. The same aperture, which serves for the mouth and the vent, is terminal, and margined with one or more rows of tentacula. These can be folded down into the aperture, and concealed under the outer envelope. When they are extended, they give the animal the appearance of a flower, increased by the lively colours with which they are adorned—a circumstance that has given rise to the popular names of *animal flowers* and *sea anemonies*, usually applied to the various species of *actinia*.

The internal structure of the genus has been carefully investigated by Dr. Spix, a Bavarian naturalist, well known by his travels in Brazil. Dr. Spix found in these animals an alimentary cavity, ending in a single aperture, very large at the lower end, and so elastic and contractile, that it could easily be turned inside out. The cavity is surrounded with flat muscles, running lengthwise and parallel. The nerve knots, or ganglia, are situated in the lowest and broadest part of the body. These have intercommunications, and are distributed to the principal organs by filaments more or less obvious.

The egg organ (*ovarium*) in a female was found to be filled with small eggs, and was composed of three or four tubes, cylindrical, cohering, and forming by their union a sort of egg tube (*oviductus*), which opened into the stomach. These tubes communicate with the tentacula in such a manner that the eggs may either make their exit through them, or through the mouth. M. Lamouroux, however, thinks that these details require to be further investigated before they can be implicitly adopted.

Baron Cuvier describes the parts in question as a rather complicated and obscure organization between the inner cavity and the outer skin, consisting chiefly of vertical and fibrous plates (*feuillets*), to which the egg organs adhere, similar to threads very much twisted. The intervals between these plates communicate with the tentacula; and it further appears that water can enter and escape through the minute

nings of these around the mouth; at least, the animal thence squirt out water.

The Abbé Dicquemare studied the *actinia* in a manner rthy of the highest praise, having observed them in all ir stages, and multiplied his experiments to a great ent. It is not, therefore, to be wondered at that most hors have contented themselves with copying his details. tells us that the forms of *actinia* vary according to their traction or expansion, presenting innumerable varieties. eir expansion is a more certain indicator of fine weather than the rise of the barometer; but this cannot be practically taken advantage of except during summer, as the cold of winter drives the *actinia* from the shore to the deeper waters, where the temperature is more equable and mild. On changing their place of abode, some abandon themselves to the mercy of the waves, others creep along the bottom, turning themselves inside out, and making use of their tentacula as feet. When they find a suitable place, they fix themselves often so firmly, that they cannot be detached without tearing their bodies. Dicquemare, and many others, suppose that this adherence, continuing even after the death of the animal can only be accounted for from a viscous fluid secreted at pleasure; while others, with MM. Bosc and Lamouroux, believe that it is caused by suction, producing a vacuum.

Our distinguished English naturalist, Ellis, has given a very minute and, so far as it goes, an accurate account of these animals in the *Philosophical Transactions*, part of which it may be interesting to quote:—

'The lower part,' he says, 'of these bodies have a communication with a firm, fleshy, wrinkled tube, which sticks fast to the rocks, and sends forth other fleshy tubes, which creep along them in various directions. These are full of different sizes of these remarkable animals, which rise up irregularly in groups near to one another.

'This adhering tube, that secures them fast to the rock or shelly bottom, is worthy of our notice. The knobs that we observe are formed in several parts of it by its insinuating itself into the inequalities of the coral rock, or by grasping pieces of shells, part of which still remain in it, with the fleshy substance grown over them. This shows us the instinct of nature, that directs these animals to preserve themselves from the violence of the waves, not unlike the anchoring of mussels, by their fine silken filaments that end in suckers; or rather, like the shelly basis of the serpula, or worm-shell, the tree oyster, and the slipper barnacle, &c., whose bases conform to the shape of whatever substance they fix themselves to, grasping it fast with their testaceous claws, to withstand the fury of a storm.

'When we view the inside of this animal dissected lengthwise, we find like a little tube leading from the mouth to the stomach, from whence there rise eight wrinkled small guts, in a circular order, with a yellowish soft substance in them; these bend over, in the form of arches, towards the lower parts of the bulb, from whence they may be traced downwards, to the narrow part of the upright tube, till they come to the fleshy adhering tube, where some of them may be perceived entering into a papilla, or the beginning of an animal of the like kind, most probably to convey nourishment till it is provided with claws: the remaining part of these slender guts are continued on their fleshy tube, without doubt, for the same purpose of producing and supporting more young ones from the same common parent.

'The many longitudinal fibres that we discover lying parallel to each other, on the inside of the semi-transparent skin, are all inserted in the several claws round the animal's mouth, and are plainly the tendons or muscles for moving and directing the claws at the will of the animal: these may be likewise traced down to the adhering tube.'—[*Phil. Trans.*, vol. lvii.]

A strong light incommodes the *actinia*, noise startles them, they are affected by odours, and fresh water causes them to die. These various feelings originate in their great irritability, which appears to increase according to their sufferings. They can support a temperature as low as 45°, and up to 140°, Fahr.; but beyond these extremes they perish. They are often left exposed to the air during spring-tides; but in such cases they always retain a great quantity of water, which they squirt out with force when molested.

These singular creatures have a power of reproduction equal to that so well known in the fresh-water polypus. (*Polypus viridis*, Bony.) They may be cut perpendicularly or across, and each cutting will give origin to a new animal. The young *actinia* are seen issuing, already formed, sometimes from the mouth; and sometimes the base of the old animal is dissevered, a portion remaining attached to the rock, where it continues to live, increasing in size, becoming more and more rounded, while, in a short time, a mouth, stomach, and tentacula are formed, presenting, to the surprise of the observer, a complete *actinia*. At length, the side portions of this base give out globules, which are detached, fix themselves upon adjacent rocks, where they grow, and produce a new colony like the parent animal.

The *actinia* feed upon *medusæ*, and other small crustaceous and molluscous animals and fishes, which they seize with their tentacula, and afterwards disgorge what they cannot digest. They are found in every sea, some suspended from the vaults of sub-marine reefs, others covering the more exposed sides of rocks with a sort of flower-like tapestry, and some confining themselves to the smooth sands, on the surface of which they spread out their tentacula, and even withdraw under the sand when danger threatens. Each species, indeed, generally selects a peculiar haunt. With the exception of the green species (*Actinia viridis*, Forskal), none of them sting when touched in the manner of the *medusæ*.

Many of the species are used as food in tropical countries, on whose coasts they are more numerous than in colder climates. Of those found in a submarine rock-basin at Barbadoes, we have a curious account by Hughes, in his Natural History of the Island.

'In the middle of the basin,' he says, 'there is a fixed stone or rock, which is always under water. Round its sides, at different depths, seldom exceeding eighteen inches, are seen, at all times of the year, issuing out of little holes, certain substances that have the appearance of fine radiated flowers, of a pale yellow, or a bright straw colour, slightly tinged with green, having a circular border of thick-set petals, about the size of, and much resembling, those of a single garden marigold, except that the whole of this seeming flower is narrower at the discus, or setting on of the leaves, than any flower of that kind.

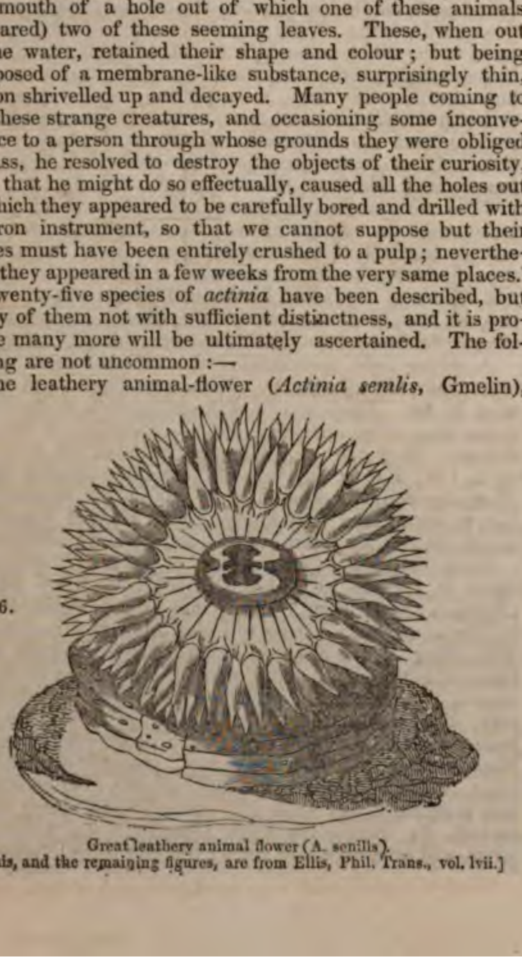
'I have attempted to pluck one of these from the rock, to which they are always fixed; but never could effect it: as soon as my fingers came within two or three inches of it, it would immediately contract close together its yellow border, and shrink back into the hole of the rock; but, if left undisturbed for about four minutes, it would come gradually in sight, expanding, though at first very cautiously, its seeming leaves, till at last it appeared in its former bloom. However, it would again recoil, with a surprising quickness, when I came within a little distance of it. Having tried the same experiment, by attempting to touch it with my cane and a small slender rod, the effect was the same.

'Though I could not by any means contrive to take or pluck one of these animals entire, yet I once cut off (with a knife which I had held for a long time out of sight near the mouth of a hole out of which one of these animals appeared) two of these seeming leaves. These, when out of the water, retained their shape and colour; but being composed of a membrane-like substance, surprisingly thin, it soon shrivelled up and decayed. Many people coming to see these strange creatures, and occasioning some inconvenience to a person through whose grounds they were obliged to pass, he resolved to destroy the objects of their curiosity, and, that he might do so effectually, caused all the holes out of which they appeared to be carefully bored and drilled with an iron instrument, so that we cannot suppose but their bodies must have been entirely crushed to a pulp; nevertheless, they appeared in a few weeks from the very same places.'

Twenty-five species of *actinia* have been described, but many of them not with sufficient distinctness, and it is probable many more will be ultimately ascertained. The following are not uncommon :—

The leathery animal-flower (*Actinia senilis*, Gmelin), which is three inches broad, with a leathery, unequal envelope of an orange colour; the tentacula in two rangs, usually marked with a rose-coloured ring. Its abode is usually in the sand.

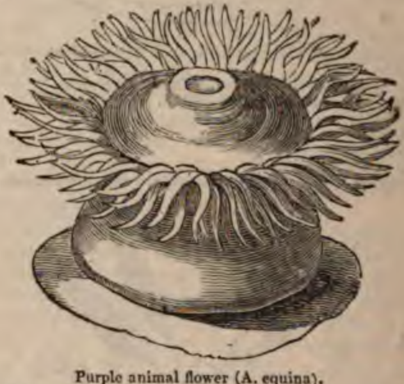
Fig. 6.



Great leathery animal flower (A. senilis).
[This, and the remaining figures, are from Ellis, Phil. Trans., vol. lvii.]

The purple animal-flower (*Actinia equina*, Dicquemare), which has a soft skin, finely striated, usually of a beautiful purple, often clouded with green. The tentacula, to the number of a hundred, vary much in colour. When the tide retires, this species may be seen ornamenting the sea-rocks with its beautiful colours—'purple, violet, blue, pink, yellow, and green, like so many flowers,' says M. Lamouroux, 'in a meadow.

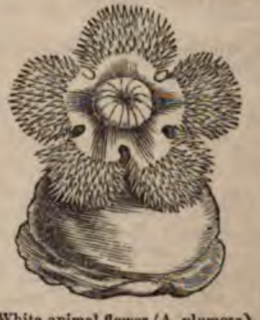
Fig. 7.



Purple animal flower (A. equina).

The white animal-flower (*Actinia plumosa*, Cuvier) is four or more inches broad, of a white colour; the margins of the mouth expanded into lobes, all furnished with innumerable tentacula. There is an inner row of these, still larger.

Fig. 8.



White, animal flower (A. plumosa).

The brown animal-flower (*Actinia effœta*) is of a clear brown, radiated lengthwise with white, and of a longish shape, often contracted at the base. The skin is glistening; the tentacula numerous. When it contracts itself there frequently issue from the mouth long filaments, which come from the egg organs (*ovaria*). It attaches itself chiefly to shells, and is very common in the Mediterranean.

The carnation animal-flower (*Actinia Jordaica*, Linnæus) has very numerous tentacula, which are of a deep crimson, and, when expanded, give the animal the appearance of a fine double carnation. The inhabitants on the shores of the Mediterranean, particularly the Italians, esteem this species as very delicate for the table.

Dr. Rüppel has recently divided from the other *actinia* those whose tentacula are branched (*Thalassiantha*, Rüppel), and those whose tentacula are so short as to be scarcely obvious (*Discosoma*, Rüppel).

Animal sunflower (A. helianthes).

ACTI'NOLITE, a crystallized mineral of a green colour, a variety of hornblende, found in primary stratified rocks, and occasionally in trap-rocks. The name is derived from ἀκτίν (*actin*), a ray of light, and λίθος (*lithos*), a stone, from the crystals being arranged in the form of rays.

ACTION (in law) is the mode of proceeding by which a man seeks to recover, through the intervention of the law that which is legally due to him: it has been defined by some ancient writers to be 'a lawful demand of one's right;' and by others, 'the right of a man to prosecute by a judicial proceeding that which is his due.' The general object of actions is to put a party into possession of a right of which he has been injuriously deprived by another. This may be effected, where lands or goods are wrongfully withheld, by the actual delivery of them to the legal proprietor; but in the case of assaults, slander, breaches of contract, or other personal wrongs, the only possible remedy is to award to the sufferer a pecuniary compensation for the injury he has sustained. By the law of England, certain specific forms are appointed in which legal remedies are to be enforced in the infinite variety of disputes and controversies arising between individuals. The various modes and instruments by which those remedies are pursued and obtained are, in popular language, called actions or suits. The principle of the law of England that for every wrong sustained by an individual there should be a remedy, does not, however, apply universally. Where the wrong is of such a nature that the detriment to the public is of more consequence than the injury to the individual, it becomes the subject of a criminal prosecution; and no right of action exists in the injured party for the remedy of his private wrong, until the offender has been tried and undergone punishment as a criminal. For those wrongs in general done by one individual to another, which do not amount to legal crimes, the proper remedy is by *action*.

Actions in England are usually divided into three kinds, according to the subjects of them; viz. real, personal, and mixed.

Real actions are so called because they exclusively refer to real property, or subjects connected with land. The law regards this as the highest kind of property, and distinguishes it from all other or *personal* property by the name of *real*. Real actions are brought for the recovery of lands or tenements, rents, advowsons, or other hereditaments. Real actions were, in the earlier periods of the history of English law, of constant and daily occurrence; and our ancient books of reports are principally occupied with cases in pleas of land, which, before the country had attained to commercial importance, was the most valuable and ordinary species of property, and, consequently, the most fruitful source of litigation. From the nicety and inconvenient length of the process they are at the present day almost entirely discontinued; and more simple and expeditious modes of trying titles to land by mixed and personal actions are generally introduced.

Personal actions are by far the most numerous class of actions. It is by them that the innumerable differences respecting debts, promises, and contracts are settled; and that compensation is sought for personal insults and injuries of almost every description, including even some of the minor crimes and misdemeanours, which thus become punishable both as crimes and as civil injuries.

Mixed actions partake of the nature of both the former actions, being brought for the recovery of lands, and also for personal damages,—either for some injury done to the land, or some other wrong, such as the illegal detention of it from the proper owner. The action of waste is a good example of this; the owner of the inheritance brings his action against the tenant for life who has committed waste on the land by cutting down trees or otherwise. In this action, he not only recovers the place upon which the waste was committed (which if it were the only effect would make it a *real* action), but by the statute of Gloucester he is entitled to treble damages as a *personal* compensation for the injury done to the land; and thus both kinds of action being joined together, give to the compound the denomination of a *mixed* action.

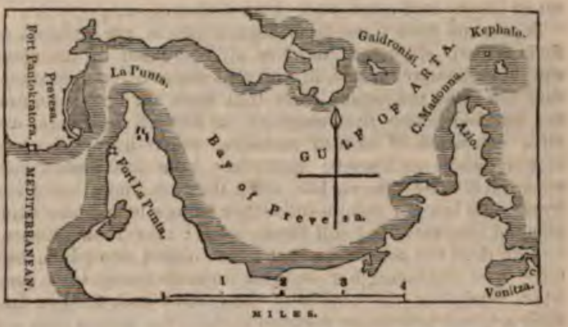
The outline of the general course of proceedings in an action at law is as follows:—The injured person (called the plaintiff) obtains a *writ* against his adversary (the defendant), who, upon being taken by virtue of the writ, gives *bail* in order to secure his appearance at the trial. When this is done, the plaintiff makes a written statement or *declaration* of the ground of his action, and prays to be restored to his right, or compensated for the injury which he alleges himself to have sustained. The defendant then *pleads*, i.e. answers the declaration by contradicting the allegations contained in it; asserting his own right, or justifying his conduct: to this the plaintiff may reply; and thus the parties may continue to altercate in legal language, or special pleading, until one or more material questions of fact are distinctly asserted by one party and denied by the other. These questions, which are called the *issues* in the cause, are then to be tried by the jury, who, after hearing the *evidence* of both parties, give their *verdict* either for the plaintiff or defendant. In pursuance of this verdict, the *judgment* is pronounced by the judges of the court to which the proceeding belongs, and the judgment is *executed* by the sheriff or other proper officer.

For more particulars respecting actions, see Bacon's *Abridgment*—Viner's *Abridgment*—Comyn's *Digest*—Jacob's *Law Dictionary*.

A'CTIUM, a point of land at the entrance of the Ambraciot bay, now the gulf of Arta, which derives its chief importance from the sea-fight which took place near it in the bay of Prevesa, between Cæsar Octavianus, afterwards the Emperor Augustus, and Marcus Antonius, B.C. 31. The latter was completely defeated, and fled with his mistress Cleopatra, who was present at the engagement, into Egypt.

The conqueror, to commemorate his victory, beautified the temple of Apollo which stood at Actium, and erected NICOPOLIS, or 'the city of victory,' on the northern side of the gulf, a few miles from the present city of Prevesa. In the article 'Achæa' we stated that Tacitus includes Nicopolis in the limits of the Roman province of Achæa; and of course Actium also would be comprised within the same political division. We find it still impossible to fix the northern limits of Achæa with accuracy; but we may here remark that what we called the Roman province of Epirus was probably contained within the limits of the extensive government of MACEDONIA.

The exact site of Actium has been a subject of dispute, some placing it at La Punta, or Fort La Punta, and others at Azio, as represented in the accompanying plan, which is taken from a very recent survey. The plan shows only part of the gulf of Arta (see ARTA). The name Azio would appear to favour the supposition of this point being the ancient Actium, but it is merely a Venetian term, probably given through some misunderstanding as to the locality of Actium. Strabo says that Actium is that point which forms one side of the entrance of the bay, and it is also clear from what he further says, that he considered the entrance of the bay to be between Prevesa and fort La Punta. He also gives to this passage a width of a little more than four stadia, or half a mile, which appears from the plan to be true when applied to the first narrow entrance, but not to the second. Anactorium, a place about four miles from the temple of Apollo which stood at Actium, is described by Strabo as 'situated *within* the bay,' while Actium 'makes the mouth of the bay.' According to this statement Actium is La Punta, and Cape Madonna is at or near Anactorium. To make it still clearer to his readers, Strabo, after describing the coast *northwards* of the entrance of the bay, comes to the *entrance* itself, following the line of coast, and this word *entrance* can only be applied to the strait of La Punta. 'Near the entrance on the right,' says Strabo, 'is the sacred place of Apollo of Actium, an eminence with a temple on it, and below, a plain with a grove of trees and a dock-yard;'



This description is said by some to suit C. Madonna better than La Punta, because Madonna is high and Punta low. But Strabo says the temple is on an eminence, and this eminence some distance from the sea; he does not say that the temple was on an eminence, which eminence was on the sea.

Actium is a name derived from a Greek word *acte*, which, in a geographical sense, is worth explaining. An *acte* is a piece of land projecting into the sea, and attached to another larger piece of land, but not necessarily by a narrow neck. Thus, the projecting land on which La Punta and C. Madonna stand can both have the name of *acte*. Herodotus calls Asia Minor itself an *acte* compared with the whole of Asia; and Africa itself (which he believed to be much smaller than it is) an *acte*, projecting from the mass of Asia.

ACTIVE MOLECULES, in plants, are extremely minute, apparently spherical, moving particles, found in all vegetable matter when rubbed in pieces and examined under very powerful microscopes. In size they vary from the $\frac{1}{15000}$ to $\frac{1}{30000}$ of an inch in diameter, and are only to be detected with lenses capable of magnifying at least 300 diameters. Viewed under favourable circumstances, immersed in water, and with transmitted light, they are seen to have a rapid motion of an oscillating nature, so that a minute drop of the fluid in which they swim seems to be as it were alive. In the pollen of plants they are extremely numerous, and perfectly distinct from each other, so that a grain of pollen crushed in water is one of the best subjects for the observer to select; he will there find the active molecules mixed with oblong or cylindrical particles, of a larger size, and equally in motion; the latter are the spermatic granules, by the agency of which the fertilization of plants probably takes place, as will be hereafter explained under the article POLLEN. To find the active molecules in other parts of plants, it is necessary that they should be crushed and rubbed in water till it becomes greenish; a drop of the coloured fluid will be found to contain vast numbers of these molecules moving about with great rapidity and exhibiting every appearance of animal life. Curious as these circumstances undoubtedly are, it is still more singular that the movements of the molecules do not cease with the life of a plant; on the contrary, they have been witnessed by Dr. Brown even in the fossilized remains of vegetables, and may be readily seen by colouring water with the dead vegetable matter called Gamboge, when the molecules are instantly set at liberty and commence their motions.

It appears from these facts that if plants are reduced to their organic elements, they are all composed of the same simple molecular matter, in different states of combination; that the huge mahogany trees that form our furniture, and the humble lichen that encrusts our ancient buildings, are alike composed of similar particles, which are capable of motion when at liberty; that they lose that power, and apparently their separate life, when they are combined by the irresistible laws of nature into other beings of a more complicated structure, but still forming life; that their inherent vitality does not cease with that of the object into which they have been combined, but endures through many ages even when buried in the bowels of the earth; and, finally, that their original powers are restored to them the instant they are liberated from their prison.

It has been thought by some, that the motions above described could be accounted for by evaporation, or by the unstable equilibrium of the molecules in the fluid in which they are suspended, or by currents in the fluid, or by a slow but gradual dissolution of the molecules, or by attractions and repulsions among the molecules themselves; but it is difficult to reconcile with such hypotheses the following ingenious experiments of Dr. Brown, the great observer of these phenomena, to whom the world is indebted for the most accurate information upon the subject. Take a drop of water in which a small quantity of the molecules is known to be floating; mix it well, by shaking it violently, among a much larger quantity of almond oil; the water will then be divided into extremely minute globules, each of which will be inclosed in a coating of oil; if the smallest of the globules, thus obtained, be examined, they will be found to contain two, or three, or even one only of the molecules, caught, as it were, in a trap, where they may be kept for many weeks and observed. Under such circumstances, no alteration whatever can be discovered in their movements, which continue the same as before the water in which they float was *ted with oil. The inversion of* this experiment by mixing a small quantity of oil, in like manner, among a large quantity of water, produces drops no bigger than the molecules themselves; but these drops, when mixed with the molecules and observed under precisely the same circumstances, exhibited no movements whatever.

For further information upon this subject, see Brown's *Account of Microscopical Observations*, made in June, July, and August, 1827.

ACTON, JOSEPH, the prime minister of the court of Naples for several years, was the son of an Irish gentleman who practised medicine at Bensançon, in France. He was born in 1737. He was originally in the French naval service; but subsequently obtained the command of a frigate from Leopold, Duke of Tuscany. In an unsuccessful expedition against Algiers, in 1774, in which the government of Tuscany co-operated with that of Spain, Acton commanded the Tuscan vessels; and by his gallant conduct succeeded in saving three or four thousand Spanish soldiers, who must otherwise have perished. His good conduct here was the cause of his advancement. He was recommended to the service of the king of Naples. His intriguing disposition secured him the favour of the king and queen of Naples; and he was successively minister of the navy, of war, of finance, and ultimately became prime minister. In his policy he was constantly opposed to the French party in Italy. Many of the persecutions for political opinions, and the violations of justice, which occurred at Naples subsequent to the period of the French invasion, in 1799, are ascribed to the power or the influence of Acton. He is said to have died in obscurity in Sicily, in 1808.

ACTOR and ACTRESS.—[See DRAMA.]

ACTS OF SEDERUNT (in the municipal law of Scotland) are statutes made by the Lords of Session, by virtue of a Scottish Act of Parliament, passed in 1540, empowering them to make such constitutions as they may think expedient for ordering the procedure and forms of administering justice. These are called Acts of *Sederunt* because they are made by the Lords of Session *sitting* in judgment.

ACTS of the APOSTLES.—[See APOSTLES.]

ACTUARY, a word which, properly speaking, might mean any registrar of a public body, but which is generally used to signify the manager of a joint-stock company under a board of directors, particularly of an insurance company; whence it has come to stand generally for a person skilled in the doctrine of life annuities and insurances, and who is in the habit of giving opinions upon cases of annuities, reversions, &c. Most of those called actuaries combine both the public and private part of the character.

An actuary combines with the duties of a secretary those of a scientific adviser to the board which gives him his office, in all matters involving calculation, on which it may be supposed that the members of the latter are not generally competent to form opinions themselves.

The name has a legal character from its being recognized in the statute 59 Geo. III. c. 128 (or the Friendly Societies' Act of 1819), which enacts that no justice of the peace shall allow of any tables, &c., to be adopted in any Friendly Society, unless the same shall have been approved by 'two persons, at the least, known to be professional actuaries, or *persons skilled in calculation*,'—a definition much too vague to be any sufficient guide. The Committee on Friendly Societies of 1825 reported that 'petty schoolmasters or accountants, whose opinion upon the probability of sickness and the duration of life is not to be depended upon,' had been consulted under this title, and recommended that the actuary of the National Debt Office should be the only recognized authority for the purposes above-mentioned; in which recommendation the Committee of 1827 joined. In the 10 Geo. IV. c. 56, however, no alteration appears in the law on this point. We may further mention that, by the Act of 1819, no Friendly Society can be dissolved, or any division of money made otherwise than in the ordinary course, without the certificate of two actuaries, that the interests of all the members have been consulted in the proposed dissolution or payment.

ACU'LEUS, or PRICKLE, in Botany, is a hard, conical, often curved, expansion of the bark of some plants, such as the rose, and is intended either for their defence against enemies, or to enable them to hook themselves upon their neighbours, so as to gain a more free access to light and air, or for other purposes unknown to us. The prickle is composed entirely of cellular tissue, which is at first soft and flexible, and only acquires its hardness and rigidity when old. In some respects it may be compared to a hair, from which it chiefly differs in its large size and greater permanence. Care must be taken by the young botanist not to confound the prickle with the spine or thorn, which is of a totally different nature. [See SPINE.] They may be distinguished by the prickle breaking readily from the bark, leaving a clean scar behind; while the spine cannot be torn off without rending through the bark into the wood itself. Leaves are often metamorphosed into spines, but never into aculei. [See METAMORPHOSIS OF PLANTS.]

ACUPUNCTURE, a term used to denote the insertion of a needle into the skin or flesh. Acupuncture is an operation which has been long in use in eastern countries, and which appears to have been adopted there from the notion that several diseases attended with severe pain arise from air or vapor pent up in the body, to which a puncture with a needle affords an outlet, and thereby removes the malady. Europeans travelling in those countries several times witnessed the practice, and were struck with the results; but either their reports were not credited, or the operation appeared to the physicians and surgeons of Europe so unpromising, that upwards of a century elapsed after the knowledge of it was familiar to many European practitioners, before a single trial of it was made. As long back as the year 1679, a medical officer in the East India Company's service states that a guard of the Emperor of Japan, appointed to conduct the English to the palace, was seized with violent pain of the abdomen, attended with vomiting, in consequence of having drank a quantity of iced water when heated. After trying in vain to relieve his complaint by taking wine and ginger, and conceiving that his suffering arose from air or vapor pent up in the walls of the abdomen, to which vapor the insertion of needles into the skin would afford an exit, he underwent the operation of acupuncture in the presence of the narrator, which was performed in the following manner:—He laid himself upon his back, placed the point of a needle upon his abdomen, struck its head with a hammer once or twice to make it pass through the skin, turned it round between the forefinger and thumb till it entered to the depth of an inch, and then, after about thirty respirations, withdrew it, and pressed the punctures with his fingers, to force out the imaginary vapor. After having made four such punctures, he was instantly relieved, and got well. Some years afterwards, a physician, who accompanied a Dutch embassy to Japan, confirmed this account, by the statement that the Japanese are in the constant habit of performing this operation in various disorders attended with acute pain, and that he himself frequently witnessed the instantaneous cessation of the pain as if by enchantment. No further notice appears to have been taken of this mode of treatment in Europe for upwards of a century, when it was alluded to by the celebrated Vicq-d'Azyr, in the Encyclopédie Méthodique, merely for the purpose of congratulating the world that the statements of Ten Rhyne and Kæmpfer, the physicians who had given the first accounts of it, had not induced any European physician or surgeon to practice it. In the year 1810, however, some trials of it were made by Dr. Berlioz, a physician of Paris, who found, or fancied he found, it so efficacious a remedy, that he was induced to employ it very extensively, and many French practitioners imitated his example with the same apparent results. It has been subsequently tried in England, and sufficient experience of it has now been obtained to prove that the operation itself is attended with little or no pain, and that it may be employed at least with safety, if not with advantage.

There are two cases in which it seems likely to be beneficial,—first, in painful local affections unattended with change of structure in the part diseased, and without local inflammation or general fever,—and, secondly, in that species of dropsy termed anasarca, in which the water is accumulated in the cells of the cellular membrane that lies immediately beneath the skin. It is probable that all the cases of the first class consist of disordered states of the nerves of the parts affected, technically termed cases of NEURALGIA. There cannot be a question that this remedy has proved beneficial in cases of this kind sufficiently often to warrant the trial of it, whenever these disorders do not yield to the ordinary modes of treatment, and under these circumstances there is the greater reason for resorting to it, since the operation occasions no pain, and since no evil consequence of any kind has ever been known to result from it. But if the part affected be inflamed, and more especially if there be any degree of febrile action in the system, the acupuncture of the part will certainly do no good, and will very likely produce mischief.

In anasarca a few punctures made with the needle will allow a ready exit to the fluid, which may continue to drain during several days in succession; and when this is the case, it invariably affords relief, and sometimes saves, and oftener prolongs, life. Scarification is a remedy of the same kind in ordinary use, but the inflammation that results from this practice is sometimes severe, and occasionally runs into mortification. Acupuncture is affirmed by many who have made trial of it to be equally effectual, and to be much less apt to be attended with these evil consequences.

The needles employed in oriental countries are always made of the purest gold or silver; those of gold are preferred, and great care is taken to obtain them well tempered. In China their manufacture is a distinct occupation, understood by few, and those few are licensed by the emperor. Some of these needles are fine, about four inches in length, with a spiral handle, for the purpose of more easily turning them, and are kept by means of a ring, or a piece of silk thread, in grooves, each capable of holding one needle: the grooves are formed in each side of a hammer, usually made of the polished horn of the wild ox, ivory, ebony, or some other hard wood; the hammer is rather longer than the needle, and has a roundish head, covered on the side that strikes with a piece of leather, and rendered heavier by a little lead within. The needles employed in Europe are of steel, long and fine, and furnished either with a knob of sealing-wax at their head, or, what is more convenient, a little handle of ivory or wood, screwing into a sheath for the needle. They are best introduced by a slight pressure, and a semi-rotating motion, between the thumb and forefinger, and withdrawn with the same motion. In cases of neuralgic pain the needle should be allowed to remain in from a quarter of an hour to two hours. It would appear, that in cases of this kind, a number of needles introduced, and hastily withdrawn, is not as effectual as the introduction of a single needle that is allowed to remain for the space of a couple of hours. When the only object is to afford an exit to the fluid collected in anasarca, of course the mere puncture is sufficient; there is no use in allowing the needle to remain.

AD LIBITUM (Latin, or *ad lib.* in Music), *at discretion, at pleasure,* denotes that the performer is at liberty to pause, or to introduce any cadence or addition of his own, according to his judgment. An accompaniment is said to be *ad libitum,* when it is not essential, and may be either used or omitted, as circumstances may require, without materially affecting the composition.

ADA'GIO, in Music, an Italian adverb, signifying *slowly, leisurely,* and used to indicate the slowest movement in music: though some writers, and among them Rousseau, have ranked *Largo* as a degree slower; but an examination of the works of those who were the earliest to use both terms, as well as of the practical interpretation of the best and most correct composers, will be sufficient to shew the error.

It is now, and has long been, the custom to point out the quickness or slowness, as also the manner or character, of a piece of music, by some Italian word, placed at the beginning of the composition. These are sometimes very inadequate to the purpose, and much is commonly left to the judgment of the performer, which but too frequently cannot very safely be relied on. The use of the metronome [see METRONOME], or, indeed, of any other kind of pendulum, which is gaining ground in spite of prejudice, fixes the intention of the composer as regards movement, that is to say, quickness or slowness. With respect to style, to the passion meant to be expressed, much must still depend on the taste and intelligence of those to whom the execution of a work is entrusted.

The five principal terms denoting the degrees of motion, beginning from the slowest and proceeding to the quickest, are—

Adagio, very slow.
Largo, slow.
Andante, a moderate time.
Allegro, quick.
Presto, very quick.

Other terms relating to slowness or quickness, are but modifications of the above.

The word *Adagio* is also used substantively · thus we say, an *Adagio* of Haydn.

The real knowledge and taste of a performer is best developed in his mode of treating an *Adagio*. What is commonly called execution, or the rapid motion of the fingers, is purely mechanical, and demands neither sensibility nor discrimination; it is a kind of sleight-of-hand, which any one by dint of animal labour may acquire: but to give true effect to a slow movement, the performer must, in addition to considerable experience and a pretty extensive acquaintance with the best schools of music, possess strong feeling, must play, or sing, with 'the same spirit that the author writ,' or he will find no willing hearers. In a word, he will either charm or disgust his audience; will shew that he either understands his art, or is wholly incapable of attaining its highest object, namely, that of touching the heart.

ADAM, the first man, and progenitor of the human race, whom God formed of the dust of the ground, on the sixth and last day of the creation, as related in the first and second chapters of Genesis. The whole of the authentic history of Adam is contained in the first five chapters of that book. His loss of the state of innocence and felicity which he originally enjoyed, is commonly known by the name of *the Fall*. It was after this event, and his expulsion from the Garden of Eden, or the terrestrial Paradise, that his eldest son Cain was born. His second son was Abel, and his third Seth, or Sheth, who was born when he was a hundred and thirty years old. But he is also stated to have had other sons and daughters, whose names are not given. He died at the age of nine hundred and thirty, and therefore, according to the commonly received computation, in the year 3074 before the birth of Christ. Many fables have been invented, and idle questions raised, by the rabbinical writers and others, respecting Adam, for which there is no warrant whatever in Scripture. The reader who may be curious to see some of these may consult the articles in Bayle, and in Calmet's Dictionary of the Bible. The word *Adam* means 'to be red,' and it is supposed that in allusion to the signification of this Hebrew verb, the earth out of which Adam was made was called 'Adamah;' while others think that the name 'Adam' contains an allusion to the reddish colour of a healthy person. See the use of the word 'adom' in the *Song of Solomon*, v. 10. According to Ludolf, *Adamah*, in the Ethiopic, means 'beautiful, elegant,' &c.; denoting man to be the chief work of God. In the New Testament the expression, the New Adam, is frequently used to designate our Saviour.

ADAM, ALEXANDER, LL.D., a late eminent teacher of Latin, who was born in June 1741, at Coats of Burgie, in the parish of Rafford, Morayshire. The station of his parents was very humble, but the parish school enabled them to obtain for their son the rudiments of a good education, at an expense not beyond their scanty means. After having acquired the ordinary knowledge of Latin here, young Adam proceeded to Aberdeen, in the hope of obtaining one of the small exhibitions, or bursaries, which are open for annual competition at King's College, to persons proposing to become students at that seminary. In this expectation, however, he was disappointed. He then resolved to enter himself at the University of Edinburgh, and to trust to his own exertions and fortitude to enable him to struggle through the usual course. This was in the winter of 1758. His difficulties and privations while attending college were very great; but he was of a character well fitted to contend with the hardships which it was his lot to encounter; and though he was sometimes reduced to such destitution as not to know where to obtain a mouthful of bread, he manfully persevered in hard study till he gained the reputation of being one of the best scholars in the university. His merits were at length rewarded by his appointment, in 1761, to the office of one of the teachers in Watson's Hospital, an institution in Edinburgh for the education and support of the sons of decayed burgesses. This situation he held till 1767, when the ability and success with which he had discharged its duties caused him to be chosen assistant to the Rector of the High School, the chief classical seminary of the city. Finally, in 1771, on the death of the rector, Adam was elected by the magistrates as his successor; and in this honourable post he remained throughout the rest of his life. The first years of his rectorship, however, were somewhat stormy. In 1772 he published a little work, entitled 'The Principles of Latin and English Grammar,' and he introduced it into the school as a substitute for Ruddiman's Grammar, which had been for many years the established manual. The four under-masters resisted this innovation, and at last the dispute grew to such a height, that it became necessary for the magistrates, as patrons of the school, to interfere. The proceedings which took place are very fully detailed in Chalmers' Life of Ruddiman (pp. 91-96, and 390-403). From the statement there given, it appears that the matter was first submitted to the town-council by the Lord Provost, on the 2d of February, 1785, when it was resolved to refer it to the decision of the Principal, and two of the Professors of the University. These learned persons took due time for deliberation, and on the 15th of October drew up a report, recommending that Ruddiman's should be the grammar regularly used in all the classes, but permitting the rector to introduce into his own class such additions from the rival work as he might deem necessary or proper. This decision, however, it would appear, did not settle the dispute. On the 7th of November we find the business again brought before the magistrates by a remonstrance from the under-masters against the decision of the professors, and a petition that the old grammar alone should be tolerated in the school. The magistrates, thus again appealed to, did not pronounce their judgment with precipitation; but at length, on the 23d of August, 1786, they issued an explicit prohibition against the rector's book, in conformity to the under-masters' prayer. Adam now in his turn became the remonstrant; but a letter which he wrote only produced a second order from the town-council, on the 29th of November, repeating and confirming the former. After this he no longer attempted to teach from his own grammar; and although the book has since gone through several editions, it has not supplanted Ruddiman to any great extent in the other schools of Scotland. Dr. Adam also published the following works:—In 1791 a volume entitled 'Roman Antiquities,' which has gone through several editions, and been translated into German, French, and Italian; in 1794, a 'Summary of Geography and History,' also several times reprinted; in 1800 a Dictionary of Classical Biography; and in 1805 a Latin Dictionary, under the title of 'Lexicon Linguæ Latinæ Compendiarium,' being an abridgment of a larger work, on which he had been long engaged. A second edition of this last has been published since the author's death, with very considerable alterations, both in the way of addition and of curtailment. Both this dictionary and the Roman Antiquities are much used in the schools of Scotland. No person filling a public situation was more universally respected and esteemed in Scotland than Dr. Adam in his latter days. His character was one of great manliness; so much so as to make him sometimes perhaps indiscreetly bold in the expression of whatever he felt. His political opinions were of a strongly liberal complexion; and he has been accused of not scrupling sometimes to give them vent with considerable emphasis in the presence of his class. But such was the general regard which was felt for him, that this charge which, especially at the time when it was made, would have seriously injured almost any other schoolmaster, scarcely affected his influence or usefulness. He was carried off by apoplexy on the 18th of December, 1809, in his sixty-ninth year, and was honoured by his fellow-citizens with a public funeral. A memoir of his life was published in 8vo., in 1810.

Of the four works just enumerated, the most valuable and the best known is the treatise on Roman Antiquities. Few books in so small a compass contain so large a mass of useful information, and the matter, multifarious as it is, is in general well digested and arranged. The chief defect perhaps, and it is one which pervades many parts of the work, is an inattention to the effects of time in changing the customs of the Romans. If the habits of one people differ from those of another, no less distinct is the character of the same nation at distant periods of its existence. While the distribution of political power and the signification of political terms vary on the one hand, on the other, the whole face of private life is changed by revolutions equally complete. Thus, though Dr. Adam has collected a large mass of facts connected with the political institutions of Rome, yet, not perceiving how the meaning of terms varied in the different ages, he has often so arranged the passages extracted by him from Latin authors on this subject, as entirely to mislead both himself and his reader. Indeed, when Dr. Adam wrote, the whole of this department of Roman Antiquities was one confused chaos, which has been only reduced again to order by the extraordinary talent and learning of Niebuhr and other writers. Again, some corrections and many additions are required in the section on the Roman year, particularly for the periods prior to the Julian correction. No little caution, also, should be observed in reading the remarks on Roman money, a subject of especial difficulty, in which it is often more prudent to be satisfied with ignorance, than to adopt the ordinary interpretations. The value and names of the Roman coins were constantly changing, and this not consistently. Secondly, the numerical notation employed by the Romans is particularly liable to corruption in the MSS.; and, even where the text is not corrupted, the interpretation is uncertain. Some other defective parts might easily be pointed out. Yet, with all these drawbacks, the work is of great value to all who read the history or the literature of Rome, and does great credit to Dr. Adam. It ought not to detract from his reputation that he has not anticipated the important discoveries made by the Germans in the last twenty years; but undoubtedly it is to be desired, and none would have desired it more than Dr. Adam himself, that the substance of these discoveries should now be incorporated in the work, in the place of what is defective or erroneous.

The treatise on Classical Biography is intended chiefly for the illustration of Roman History, and within these limits has a decided superiority over any other work in our language. It deserves a much more extensive circulation than we believe it possesses in England. And we may say the same of Dr. Adam's Latin Dictionary, which has been prevented from superseding the octavo edition of Ainsworth's Dictionary, perhaps only by the inconvenient arrangement adopted by Adam, who often neglects the alphabetical order, to bring together words etymologically connected. The summary of History, and Geography, published by Dr. Adam, has in parts great merit, but it aims at much more than can be fairly executed within the limits. We need only say that it professes to give, 1st, A summary of all history, ancient and modern, Grecian, Roman, Persian, English, French, German, Indian, American, &c., &c., with the manners and customs of these nations; 2dly, The mythology of the Greeks; 3dly, The geography of all ages and all countries, not excluding even the local situations of remarkable cities; 4thly, An account of the progress of astronomy and geography, from the earliest periods to the present time, with a brief account of the planetary system. And not satisfied with all this, the publishers have added an extensive index of geography, and thirteen maps of little value. Bulky as the volume is, there is not, and cannot be, room for information of any value, on so many points. Like a map on a small scale crowded with names, its tendency is to confound rather than inform the understanding. But when we look at all that Dr. Adam did, we can fairly say that no writer in the British islands has ever done more to assist the young student of Latin, or, what is perhaps still more important, to connect that study with the attainment of general knowledge.

ADAM, JAMES, an architect of the last century, who is not at all known but as the partner and associate of his brother Robert, the subject of the following article. He died in 1794.

ADAM, ROBERT, an architect who was extensively employed both in England and Scotland, but more particularly in London, in which city he also engaged in some very considerable building speculations. He was born at Kirkaldy, in Fifeshire, according to some authorities, and, according to others, at Edinburgh, in the year 1728, and was the son of William Adam, Esq., of Maryburgh, near Kirkaldy, who is said to have furnished the designs for Hopetoun House and the Royal Infirmary of Edinburgh; but whether he was himself professionally an architect or not, does not appear. Robert received his literary education at the University of Edinburgh; and, from his father, it seems most likely, he derived instruction in the principles and practice of his future profession. During this period he had the advantage of the society of many distinguished literary and scientific men, who were the friends and companions of his father, and among whom were numbered the great names of Hume, Robertson, and Adam Smith.

When he was in his twenty-sixth year, Mr. R. Adam went to Italy in pursuit of professional knowledge, and remained there several years. His contemporaries, James Stuart and Nicholas Revett, were, at the time of Adam's residence in Italy, engaged in exploring, and preparing for publication, the architectural remains of Athens; but so little was Grecian architecture known and appreciated, that he went, instead, to Spalatro in Dalmatia, to measure and delineate the ruins of the palace of Diocletian there, a structure indicating alike the decline of civilization and the progress of barbarism. In this tour he was accompanied by Clérisseau, a French architect, whose name is connected with a work on the remains of a Roman temple at Nismes, in Languedoc. Mr. Adam returned from the continent about the year 1762, and settled in London, and shortly after published there, in a large folio volume, engraved representations and descriptions, with attempted restorations, of the Dalmatian palace before mentioned. These, like many other attempts of the kind, are not consistent, in the more important particulars of architectural arrangement, with the evidence afforded by the remains themselves, and by the remains of other palatial and domestic edifices of the same and earlier date; some of these, however, were not accessible when Mr. Adam wrote.

About the same time, 1763-4, Mr. R. Adam was appointed architect to the king. This fortunate position made him what is termed fashionable, and he found extensive employment. In the course of a very few years he designed, and, in conjunction with his brother James, executed a great many public and private buildings in England and in Scotland. In 1773 the brothers commenced the publication of their works, in large folio engravings, with letter-press descriptions and critical and explanatory notes, in numbers, which were continued at intervals down to 1778. The principal designs included in these are, the screen fronting the high road, and the extensive internal alterations of Sion House, a seat of the Duke of Northumberland, near Brentford in Middlesex; Lord Mansfield's mansion at Caen-wood, or Kenwood, also in Middlesex; Luton House, in Bedfordshire, erected for Lord Bute; the screen to the Admiralty Office, London; the Register Office, Edinburgh; Shelburne House, now Lansdowne House, Berkeley-square, London; the parish church of Mistley, in Essex, &c. &c. At a later period the Messrs. Adam designed the infirmary at Glasgow, and some extensive new buildings in the University of Edinburgh, though their practice, after the year 1780, lay principally in London, where a great many of their productions still exist, and are easily recognised by any one accustomed to discriminate architectural design. We may mention Portland, Stratford, and Hamilton Places, the south and east sides of Fitzroy Square, and the buildings of the Adelphi as the most extensive of their works. Much of what the Messrs. Adam did was in the capacity of speculating builders. The Adelphi was a speculation of their's, and is understood to have been an unsuccessful one. The substructions of buildings of such a kind, and in such a situation as those of the Adelphi Terrace, were necessarily so expensive as almost to preclude the possibility of an adequate return. It may be further remarked that their interest in, and connexion with, this last-mentioned expensive undertaking, is intimated by the name 'Adelphi,' which is the Greek term for 'brothers;' and by the application of their own name, 'Adam,' to the principal street leading to the terrace, and of their respective Christian names, 'Robert' and 'James,' to two of the minor streets.

The Messrs. Adam were among the first, if they were not themselves the very first, to make use in London of a stucco in imitation of stone, for external architectural decorations; and that which they employed was an oil cement or composition, invented by Liardet, a Swiss clergyman resident in this country, who had obtained a patent for the preparation of it, which patent they purchased. This was infringed by pretended improvers, and the proprietors were thereby involved in a troublesome and expensive suit to protect their own interests, and were, moreover, involved in disputes with rival builders and surveyors. Most of the works produced by the Messrs. Adam in the course of their practice and business, as architects and builders, where stone is not used, are either faced entirely, or their architectural decorations are formed, with this composition, which has endured, now at the end of half a century, far better than was predicted at the time.

The style of architecture introduced by the Messrs. Adam was peculiar to themselves, and very faulty; but there is nevertheless an air of prettiness, and some good taste in it; and the credit may certainly be claimed for its authors of having done much to improve the street architecture of London, for which species of composition their style was better adapted than for detached and insulated structures. Their taste seems to have been slightly affected, and in that slight degree beneficially, by the Greek style of composition which Messrs. Stuart and Revett were then making known, but they certainly were far from entering into the spirit of it; they departed moreover almost entirely from the laws and usages of the Italo-Vitruvian school, which was then called classical, and introduced many deviations alike inconsistent with the styles of Greece and Rome, with the laws of the schools, and with sound sense and good taste. The entire omission, or contraction, of an architrave in their entablatures, the extravagant breadth of their friezes, the shallowness and almost universal meanness of their cornices, and the still meaner and more tasteless style of the decorative ornament with which they beplastered their friezes and ceilings, are among the most glaring faults of their peculiar manner. In their insulated compositions especially, the worst of these faults are aggravated by varieties of them being introduced, not only into different, but also into the same elevations of the same structures, which should at least harmonize even in their defects. Both Kenwood and Luton Houses are examples of this; they both have mean entablatures, which are differently composed and proportioned, on the same and on different fronts of the respective edifices. In mere street-fronts the style of the Messrs. Adam, as we have before intimated, is not only less offensive, but it is at times made even pleasing. The front of the British Coffee-house, in Cockspur Street, though a mere trifle, is by far the best of their fronts with which we are acquainted; and the Admiralty screen has more beauties and fewer defects than most things of the kind they executed; but this last, it must be confessed, is less after their own manner, and more in conformity with the rules of art.

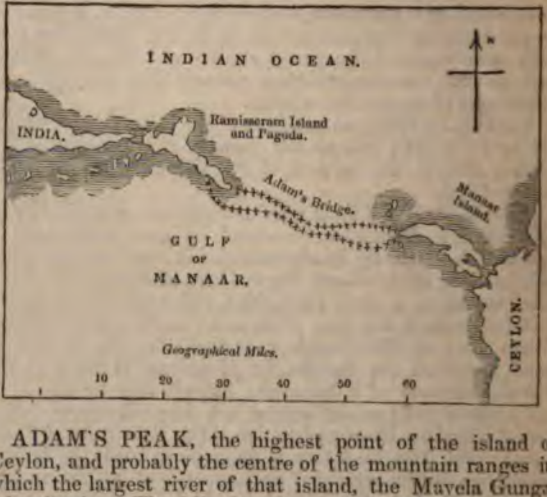
Mr. R. Adam did not retain the appointment of architect to the king more than four or five years, for he resigned it on being returned to parliament for the county of Kinross in 1768. This latter circumstance, however, does not appear to have interrupted his professional avocations, for we find that he continued to be actively engaged in business down to the period of his death, which took place in March, 1792, in the sixty-fourth year of his age, in consequence of internal hemorrhage, occasioned by the rupture of a blood-vessel. He was buried in Westminster Abbey, in the south transept of which is a tablet to his memory.

As an architect Mr. Adam displayed an original and independent mind; for it required, in his day, no small degree both of originality and independence to break through the trammels which had been imposed upon architecture. This Adam did, nevertheless, and though the result was that he became a mannerist, after a very peculiar, and, as we have shown, not very elevated or classical style of his own, the effect on English architecture was, on the whole, good. With Mr. Adam, we believe originated the idea of giving to a number of unimportant private edifices the appearance of one imposing structure, by external architectural arrangements; and he certainly has the credit of having carried this principle extensively into effect in several of the instances we have mentioned.

As a member of society, Mr. Adam enjoys the reputation of a kindly disposition, of great sweetness of manners, and of a high moral character, which assured to him affectionate regard in private life, and confidence and esteem in public.

ADAM, (Sculptors.) There were three brothers of this name, who all enjoyed some reputation as sculptors in France in the early part of the last century. They were the sons of a sculptor named Jacob-Sigisbert Adam, who lived at Nancy. The eldest, Lambert-Sigisbert, was born there on the 10th February, 1700, and made his first appearance at Paris in 1719. After remaining in that city for four years, he gained the first prize in the Academy, and proceeded to Rome on a pension allowed him by the king. Here he spent about ten years, and among other works furnished the design which was adopted by Clement XII., one of sixteen which were presented for the intended fountain of Trevi. The offers of the French government then induced him to return to Paris. On the 25th May, 1737, he was admitted a member of the Academy, and he was afterwards appointed professor in that institution. The two best known of this sculptor's productions are, a group of Neptune and Amphitrite, which he executed for the Basin of Neptune at Versailles, and on which he spent five years; and a figure of St. Jerome, originally intended for the Hospital des Invalides, but now placed in the church of St. Roch, at Paris. They are fair specimens of the French school of that age, which, however, was one of the least brilliant periods in the history of modern art. Adam published, in 1754, a work entitled *Recueil de Sculptures Antiques Grecques et Romaines*. He died of apoplexy on the 13th May, 1759. Nicolas Sebastian, the next brother, was born on the 22d March, 1705. He came to Paris at the age of eighteen, and went to Rome in 1726, where, two years after, he obtained one of the prizes at the Academy of San Luca. Having remained here for nine years, he returned to Paris; and after some time was also, like his elder brother, received into the Academy. Among the designs which he produced was one for the Mausoleum of the Cardinal de Fleury. His two principal works were a tomb for the wife of King Stanislaus of Poland, and his Prometheus chained to a Rock (which has been commonly assigned by mistake to his elder brother). For the latter work he had an offer from the King of Prussia of 30,000 francs; but he declined accepting it, on the ground that the sculpture belonged to his own sovereign, for whom it had been at first intended. He died on the 27th March, 1778. The third brother, François-Gaspard, was born in 1710. He made his way, like his elder brother, to Rome, and also on his return from Italy fixed his residence in Paris. He worked for some years at Berlin, in the service of the King of Prussia, and died at Paris in 1795. [Abridged from the *Biographie Universelle.*]

ADAM'S BRIDGE, a series of sand banks, which, with two small islands, extend from a point in the southern peninsula of India (140 miles north-east of Cape Comorin) to the opposite island of Ceylon. The width of the channel is about sixty geographical miles, and there are only two navigable passages in it. One, called the Manaar passage, which separates the small island of Manaar from the adjacent coast of Ceylon, has not more than four feet water at flood-tide. The other, and more northern passage, is called the Paumbeen, and separates the main land from the island of Ramisseram, celebrated for its great pagoda and extensive remains. The Paumbeen passage is very narrow, and not more than six feet deep at high water. The space between the two nearest points of Manaar and Ramisseram, which is about thirty miles wide, is a bank of sand, only covered at high water. Thus, if a vessel of moderate size has occasion to sail from any one point north of the Bridge into the Gulf of Manaar, it must make the whole circuit of the island of Ceylon. The ninth degree of north latitude passes through the southern part of Manaar Island. [See *Journal Educ.* No. 6.]



ADAM'S PEAK, the highest point of the island of Ceylon, and probably the centre of the mountain ranges in which the largest river of that island, the Mavela Gunga, takes its rise. The following description of it is by Robert Knox, an Englishman, who was near twenty years a prisoner in the island. (London, 1681.)

'On the south side of Conde Uda is a hill, supposed to be the highest on this island, called, in the Chingulay language, Hamalell; but, by the Portuguese and the European natives, Adam's Peak. It is sharp like a sugar-loaf, and on the top a flat stone with the print of a foot like a man's on it, but far bigger, being about two feet long. The people of this land count it meritorious to go and worship this impression; and generally about their new year, which is in March, they, men, women, and children, go up this vast and high mountain to worship.—Out of this mountain arise many fine rivers, which run through the land, some to the westward, some to the southward, and the main river, viz. Mavelagonga, to the northward.'

The print of the foot is supposed to be that of Buddha, which he left when ascending to heaven. He has no temple on this mountain, according to Knox, but 'unto this footstep they give worship, light up lamps, and offer sacrifices, laying them upon it, as upon an altar.' Besides the footstep on the mountain-top, there was, in Knox's time, a tree in the north part of the island at Annarodgburro, which was annually resorted to at the same time with the footstep, and was held in equal honour, as it was said to have come flying over from the mainland, and to have planted itself. When Buddha was on the earth, he used often to sit under this tree.

The Greek geographer Ptolemy, who had some knowledge of Ceylon, gives to Adam's Peak the name of Male, which is evidently the same word as the Hamalell of Robert Knox.

Adam's Peak is in about 6° 50′ N. L., 80° 35′ E. L., and 45 miles E. S. E. of Columbo, which is on the west coast. The elevation of the mountain is about 7000 feet. The principal materials of which it is composed are gneiss and granite. Thick forests clothe the lower part of the mountain, which is, as Knox describes it, very steep and difficult of access. The path which leads to the summit is the work of the devotees who go to pay their respects to the sacred footstep.

A'DAMANT, a word no longer employed as a scientific term, but used chiefly as a poetical expression synonymous with diamond, or as descriptive of some other hard precious substance, or merely to convey an idea of extreme hardness. Milton, Pope, and Gray, make use of it in these different senses, as well as the adjective *adamantine*. The real and primary meaning of the word adamant, which is derived from the Greek, is *unbroken*, or *what cannot be broken*.

ADAMAN'TINE SPAR, a simple mineral, more commonly denominated CORUNDUM by mineralogists, the name given to it in India, from which country it was first brought to Europe. The first specimens of it were sent by Dr. Anderson, of Madras, to Mr. Berry, a lapidary in Edinburgh, as the substance used in India to polish masses of stone, crystal and all other gems, except the diamond. It was examined by the celebrated Dr. Black, who ascertained its peculiar nature, and from its great hardness, he called it adamantine spar. With the exception of the diamond, it is the hardest substance known. It contains about 90 per cent. of alumine, a little iron, and a little silica, is usually of a pale grey or greenish colour, but is also found of various tints of red and brown. It is usually met with in rough ill-defined crystals, in granite, and sometimes in primary limestone, and is found in China, many parts of India, and occasionally in different parts of Europe. EMERY, the well known substance used in the cutting and polishing of glass, in polishing steel, making razor-straps, and similar purposes in the arts, is a granular variety of corundum, usually very much mixed with iron ore. It is chiefly imported from the Isle of Naxos, in the Grecian Archipelago, but is also found in Saxony. The SAPPHIRE is a remarkable instance how the mysterious chemistry of nature in the mineral kingdom produces from the same elements substances the most different in external form; this beautiful precious stone yielded by the analysis of Chenevix 94 per cent. of alumine; and Tennant found in emery, when freed from its admixture of iron, 92 per cent. of the same earth. The sapphire is, after the diamond, the most valuable of gems; it is usually dark blue, but also occasionally colourless, and the precious stones called by lapidaries *oriental* ruby, *oriental* topaz, *oriental* amethyst, and *oriental* emerald, are red, yellow, violet, and green *sapphires*, distinguishable from the other gems of the same name which have not the prefix *oriental*, by their greatly superior hardness and greater specific gravity. Sapphires are found in gravel and sand in the island of Ceylon and in Pegu, but they have never been seen in a matrix. They are also occasionally found in gravel in different parts of Europe, and they have been met with of a clear blue colour and crystallized, in the lava of Nieder Mendig, near Andernach on the Rhine.

ADAMS, JOHN, a distinguished American statesman. He was born in the town of Braintree, near Boston, in Massachusetts, on the 19th October, 1735, of a family which had come from England at the first settlement of the colony. At the usual age he was sent to Harvard College, in the neighbouring town of Cambridge; after leaving which, he proceeded to study the law, and was in due time called to the bar. He soon raised himself, in the profession which he had thus chosen, to great reputation, and extensive practice. In 1765 he published anonymously, in the Boston Gazette, a series of papers under the title of an Essay on Canon and Feudal Law, intended to expose the absurd and oppressive character of these systems, which attracted considerable notice, and were, in 1768, collected and reprinted in London. In 1765, when the first opposition of the people of America was excited by the Stamp Act, Mr. Adams took an active part in those measures of constitutional opposition which eventually forced the repeal of that obnoxious statute. An offer of the lucrative office of Advocate-General in the Court of Admiralty, made to him the following year by the Crown, with the view of detaching him from the popular cause, was instantly rejected. He was one of the *select* men, or state-representatives, deputed by the several towns of the province, who in 1770 met in convention at Boston, on the announcement of the intention of the British Government to station a military force in that town, in order to controul the populace, exasperated by the new act imposing duties on glass, paper, tea, &c., which had been passed in 1767, and by the other measures which indicated a determination in the mother country to maintain at least the principle of her late aggression. Soon after this, however, Mr. Adams gave a proof both of his intrepidity, and of the moderation which was associated with his zeal, by undertaking the defence of Captain Preston and his men, who, on the 5th of March, 1770, had killed several of the people of Boston in a riot—a transaction which used to pass under the name of the Boston massacre. He delivered a very powerful speech on this occasion, when the jury acquitted all the prisoners of murder, and only found two of them guilty of manslaughter. To the honour of his countrymen, the part he had thus taken did not diminish his popularity or influence; and he continued, during the remaining first years of the struggle, to exert himself conspicuously in the front rank of the friends and supporters of the colonial cause. In 1773, and again in 1774, he was returned by the House of Assembly a Member of the Council of the State; but on both occasions the governor, General Gage, put his negative on the nomination. The latter year, however, he was elected one of the four representatives from the province of Massachusetts Bay, to the General Congress, which met at Philadelphia on the 26th of October, and which, among other proceedings, entered into a resolution to suspend the importation of British goods; and he was also a member of the second assembly of the same nature, held some time after, which took measures to enrol the people in an armed national militia. In 1775 he was offered the appointment of Chief Justice of his State; but this he declined, feeling that he could better serve his country in another sphere. It had already become evident to many, indeed, that the contest with Great Britain must finally be decided by the sword; and Adams seems to have been one of the first who adopted this conviction. He was accordingly one of the chief promoters of the Declaration of Independence, passed on the memorable 4th of July, 1776. The motion was made by Mr. Lee of Virginia, and seconded by Mr. Adams; who, along with Mr. Jefferson, was appointed the sub-committee to prepare the declaration. It was actually drawn up by Mr. Jefferson. In November, 1777, Mr. Adams proceeded to Paris, as a Commissioner from the United States to that court; and after remaining for a short time in France, returned to America, when he was elected a Member of the Convention for preparing a new constitution for Massachusetts. In 1780 he was sent by the United States as their ambassador to Holland; from which country, about the end of 1782, he proceeded to France, to co-operate with Dr. Franklin and his brother commissioners in the negotiations for peace with the mother country. In 1785 he was appointed the first ambassador from the United States to Great Britain; and he had his first audience with his Majesty in that character on the 2d of June. He remained in England till October, 1787. In 1789, when Washington was elected President of the Union, Mr. Adams was elected Vice-President, and he was re-elected to the same office in 1793. In 1797, on the retirement of Washington, he was chosen President; but he failed to be re-elected on the expiration of his first term of four years, his competitor, Mr. Jefferson, who had also been opposed to him on the former occasion, having a majority of one vote. The general tone of the policy of Adams had been opposed to that of the democratic party, which was represented by Jefferson; but he does not appear to have given complete satisfaction to the other great party whose leading principles he espoused. On failing in being re-elected president, he retired from public affairs to the quiet of his country residence at Quincy; declining, although nominated, to stand candidate at the next annual election for the governorship of Massachusetts. The rest of his life he spent in retirement. For some years before his death his health had become extremely feeble, and at last little more remained of the once active and eloquent statesman than the mere breath of life. In this state he was when the morning arrived of the 4th of July, 1826, the fiftieth anniversary of the Declaration of Independence. Awakened from sleep by the ringing of bells and other rejoicings of that grand jubilee, the venerable patriot was asked if he knew the meaning of what he heard. 'Oh, yes,' he replied, the glow of old times seeming to return to him for a moment, 'It is the glorious 4th of July!—God bless it—God bless you all!' Some time after he said,—'It is a great and glorious day,'—adding, after a pause apparently of deep thought, 'Jefferson yet survives.' These were the last words he was heard to utter. About noon he became alarmingly ill, and at six in the evening he expired. The same day also terminated the career of Jefferson, his fellow-labourer in laying the foundations of the independence of their common country, and afterwards his successful rival. Except for a short time, however, these two distinguished men were friends throughout life. Besides the early publication that has been mentioned, and many fugitive pieces, Mr. Adams was also the author of a work first printed in 3 vols. 8vo., in 1787, while he was in this country, under the title of 'A Defence of the Constitution and Government of the United States,' but afterwards remodelled and reprinted in 1794, with the new title of a 'History of the Principal Republics of the World.' It is designed to serve, by an ample induction from history, as a vindication of the federal principles of the American Constitution, an attachment to which, indeed, has always been considered the distinctive characteristic of this statesman and his party. His son, John Quincy Adams, is still alive, having spent a large part of his life in the service of the United States, and like his father, having attained the honour of being *once* elected to fill the office of chief magistrate of the republic. [See *Encyclopædia Americana.*]

ADAMS, SAMUEL, a conspicuous actor in the American Revolution. He was born at Boston on the 27th of September, 1722, and received his education at Harvard College. After passing through the usual course of instruction at that college, he applied himself to the study of divinity, with the intention of becoming a preacher in the Calvinistic communion, to which his family belonged. Although he abandoned these professional views, probably his early theological studies had considerable influence in forming the character of the man; and he at any rate retained to the end of his life a stern and somewhat intolerant attachment to the religious principles in which he had been educated. He was better fitted, however, for the rude contests of politics than the peaceful ministrations of a Christian clergyman. Accordingly, on the first outbreaking in his native province of the irritation and disturbances occasioned by the Stamp Act in 1765, Adams threw himself with zeal and determination on the popular side. From that moment the forwarding and maintaining of the cause of his country's independence became the business of his life. The same year in which the Stamp Act was passed, he was deputed by his fellow-citizens as one of their representatives in the legislature, of which assembly he was immediately after elected clerk. In 1774 he had the honour of being sent as one of the four members from Massachusetts to the first Congress. His name appears subscribed to the Declaration of Independence in 1776. After the conclusion of the war he was nominated a member of the convention for settling the constitution of Massachusetts; and he afterwards occupied a seat in the senate of that state, and presided over it for some years. In 1789 he was elected to the office of lieutenant-governor, and in 1794 to that of governor, to which he was re-elected annually till 1797, when he retired from public life. He died at Boston on the 2d of October, 1803. Samuel Adams was one of the firmest and most active patriots of the Revolution, and powerfully contributed to the happy termination of the great cause to which he devoted his life. But he was not a politician of very enlarged views; and useful as he proved in the subordinate sphere in which he acted, there can be little doubt, from many parts of his conduct, that the national struggle would hardly have been brought to the successful issue with which it was eventually crowned, if it had not been guided by wiser heads than his. He was actuated in the whole course of his political career almost exclusively by one idea or feeling—jealousy of delegated power, however guarded. 'Samuel Adams,' said one of his friends and admirers, 'would have the State of Massachusetts govern the Union, the town of Boston govern Massachusetts, and that he should govern the town of Boston, and then the whole would not be intentionally ill-governed.'—[Abridged from the *Encyclopædia Americana.*]

ADANSON, MICHAEL, a French naturalist of high reputation, was born at Aix in Provence, April 7, 1727. He was of Scotch extraction, but his family had become exiles in consequence of the troubles that distracted Scotland in the early part of the 18th century. At a very early age he was placed at the University of Paris, under the care of the celebrated Réaumur and of Bernard de Jussieu; and it is supposed that from these preceptors he imbibed that love of the study of Natural History, by which he afterwards became distinguished in so eminent a degree. His success in carrying off the academical prizes from his competitors soon attracted attention, and Needham, the well-known microscopic observer, having upon one occasion been witness to his triumph, presented him with a microscope, accompanied, it is said, by these prophetic words, 'Young man, you have studied books enough; your future path will be among the works of nature, not of man.' At this time great originality of thought and a strong bias for systematic arrangement had already begun to develope itself. Emulous of the reputation of Linnæus, which had already found its way among the French, young Adanson is said, when only fourteen, to have sketched out not less than four methods of classifying plants. His friends had destined him for the church, but a feeling that his pursuits, and perhaps his temper, were but ill-adapted to the duties of the priesthood, induced him to resolve upon seeking some other employment, in case his slender patrimony should prove insufficient for his wants.

The genius of Adanson was much too active to allow him to remain in the walks of quiet life. An opportunity occurring of visiting the country whence ivory, and gums and frankincense were procured, he eagerly embraced the occasion, although at the expense of a considerable portion of his fortune. At that time the natural history of Africa was almost unknown, except from such of its commercial products as were brought to Europe. In 1748 he embarked for Senegal, being then twenty-one. Five years were spent by him in this colony, during which time he succeeded in forming considerable collections in every branch of natural history. Not only were botany and zoology the objects of his attention, but he amassed a large store of meteorological observations; he made himself acquainted with the language of the native tribes, and carefully preserved their respective vocabularies; he traced the river Senegal to a considerable distance in the interior, formed charts of the country, and finally returned to Paris in 1753, rich in knowledge, but impoverished in worldly means. His *Natural History of Senegal*, published at Paris four years afterwards, is a mass of original views, and of valuable practical information. Among other things, it contained the first attempt upon record of classifying shells according to the animals they contain, instead of their external forms alone. The opinions that Adanson had early held of the insufficiency of the classifications in natural history at that time received in Europe, had become confirmed by his discoveries in Africa. He saw that however easy and complete the systems of Linnæus and Tournefort might seem to those acquainted with the European Flora only, they were both essentially defective when applied to vegetation in a more extended manner. He perceived that the sexual system of Linnæus was founded upon incomplete and partial views. To the method of Tournefort the objections appeared fewer, and accordingly he determined to attempt a classification of his own, of which that of Tournefort might serve as the basis. This appeared in 1763, in two volumes 8vo., under the name of *Families of Plants*. In this work Adanson particularly insisted upon the indispensable necessity of a system being so far in accordance with nature, that all those objects which most resemble each other may be classed together;

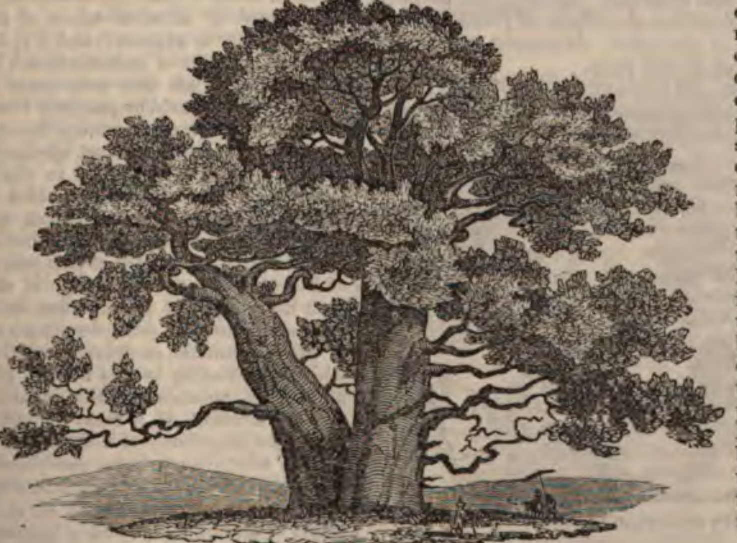
he demonstrated that, to effect this, it is absolutely necessary for a system to be founded upon a consideration of all the parts of the objects which it comprehends, and that it cannot be confined to differences in the nature of a few organs only; the artificial system of Linnæus he for that reason most justly considered inferior to the method of Tournefort. In many respects this work of Adanson's deserves the eulogium passed upon it by one of his historians, who pronounces it a production not more brilliant than profound; it is a collection of a great number of just views of the analogies that exist among plants; it no doubt furnished many important suggestions to Jussieu in the construction of his system; and it is to this day consulted by those who make the philosophy of botany their study. Unfortunately for its author, and still more for science, his views were more advanced than those of his contemporaries; his perceptions of botanical truths, however just, were of a nature not to be valued by those who had less experience or acuteness than himself; he also attempted to introduce a barbarous nomenclature, which, it must be confessed, was at variance with common sense; and what was worse than all, he had unceremoniously rejected that system of Linnæus which had become the basis of the botanical creed of almost all Europe. For these reasons, notwithstanding the high character of Adanson's *Families of Plants*, they have scarcely had any circulation beyond France; and when, in 1789, the *Genera Plantarum* of Jussieu made their appearance, the utility of his work generally ceased.

From this period we have little to record concerning the scientific career of Adanson. A few miscellaneous papers, a chimerical project of a vast Encyclopædia of Natural History to contain 40,000 figures, and a portion of the early part of the botanical division of the Supplement to the French Encyclopædia, are all that he has executed. Up to the period of the French revolution, he appears to have been chiefly occupied in amassing collections for the stupendous work he had in contemplation, and in making experiments upon vegetable physiology. That political catastrophe overwhelmed him in the ruin it brought for a time upon his country; the little that remained of his fortune was annihilated; he had the mortification to see his plantations of mulberry-trees, which had been long the object of his simple care, destroyed by a ferocious rabble; and he fell into so lamentable a state of destitution, that when upon the establishment of the Institute of France some years after, he was invited to become one of the earliest members, he was obliged to refuse the invitation to attend 'because he had no shoes.' In his latter days he enjoyed a small pension from the French government; but his constitution was broken by the calamities he had undergone; a complication of maladies tormented him, a softening of the bones confined him to his bed, and on the 6th August, 1806, he was finally released from his afflictions by the hand of death, in the eightieth year of his age.

While the scientific character of Adanson has been, perhaps, too highly estimated by his own countrymen, it has been most unfairly depreciated by others. That he was a man of a very comprehensive mind, of considerable learning, much experience, great acuteness, and perfect independence of thought, is evident from his writings. This would be clear from his miscellaneous memoirs, if we had not his greater works to judge by. He is, however, a very instructive instance of the folly of eccentricity, and of the evils to which a disregard of established ideas in unimportant matters is sure to lead; his example shows that the value of the most useful discoveries may be altogether destroyed by a capricious affectation of unmeaning singularity. Had he been less absurd in his nomenclature, his popularity would have certainly anticipated that of Jussieu, and might have struck some twenty or thirty years off the reign of the Linnæan school. It would have been impossible for the great Swedish autocrat in science to have resisted the attacks of so active and vigorous an assailant, who had knowledge and truth on his side. Adanson has been charged with being led by pique and wounded pride, to the opinions he held regarding Linnæus and his system; this has been inferred from a few complimentary expressions in a letter dated not more than a year anterior to his first attack upon the Linnean system—expressions which have been thought to prove that the public declarations of Adanson were at variance with his private sentiments: it is, however, far more probable, as it surely is more charitable, to suppose that he was really led by that love of truth and honesty of purpose, which we have ample evidence to prove that he possessed. As a philanthropist, his name will always be respected by every friend of civil liberty; for he was among the first to plead the cause of the slaves, and to insist upon the impolicy, as well as injustice, of forced labour. In 1753, a plan, very like that upon which the new American colony of Liberia has been established, was presented by him to the French government, for the whole of the French provinces in Africa. The ministers of such a sovereign as Louis XV. were not the men to listen favourably to a project of this nature, and it fell to the ground. Such was his love of his country, that although his circumstances do not seem ever to have been very good, he had firmness enough to resist offers from the Emperor of Austria, Catharine of Russia, and the king of Spain, to enter into their service. Under the cruel misfortunes that attended his latter days, he is represented to have exhibited great patriotism and magnanimity; which was the more to be commended, because he was naturally of an impetuous and irascible temper. [See *Bibl. Univ.*, vol. i. *Spreng. Hist. R. herb.* v. ii., *art.* Adanson, *in Rees' Cycl. Suppl.*]

ADANSONIA, so called in honour of Michael Adanson, a French naturalist, the subject of the preceding article, is an extraordinary tree found in Africa within the tropics, particularly in Senegal, where it is called *Baobab*.

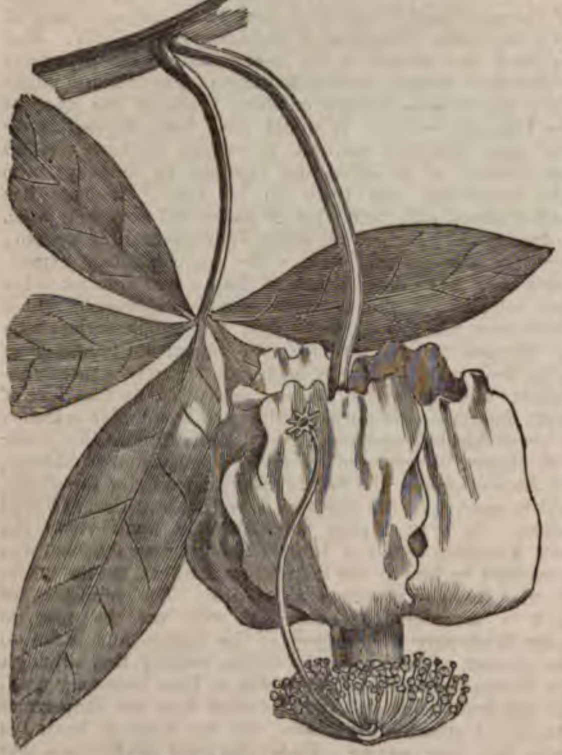
The celebrated traveller Humboldt considers it as the 'oldest organic monument of our planet,' in consequence of the calculations of Adanson that specimens, still found on the north-west coast of Africa, are probably 5000 years old; these calculations are, however, open to many objections. [See Age of Trees.] In appearance, *Adansonia* is unlike any other known tree: the enormous dimensions of its trunk bear a striking disproportion to the other parts; it is not unusual to find a trunk not more than twelve or fifteen feet from the root to the branches, with a circumference of seventy-five or seventy-eight feet. The lower branches are very long, and at first horizontal, extending, perhaps, sixty feet; the consequence of which is that they bend down to the ground, entirely hiding the trunk, and giving the tree the appearance of a huge mass of verdure. The wood is very soft, even when in perfection, and is subject to a disease which may be compared to the very malady of which its celebrated discoverer died,—a sort of softening of all the hard parts, so that the least storm is sufficient to overthrow and dismember its enormous bulk. A curious practice prevails among the negroes of hollowing its trunk out into chambers, and therein depositing the bodies of malefactors, or of persons to whom the usual rites of sepulture are denied. In this situation the bodies become dried up, and soon acquire the state of perfect mummies.



[Adansonia digitata.]

Adansonia belongs to the natural order *Bombaceæ*, among which it is at once known by a broad tube of stamens and deciduous calyx, combined with a woody closed-fruit, containing a soft pulp.

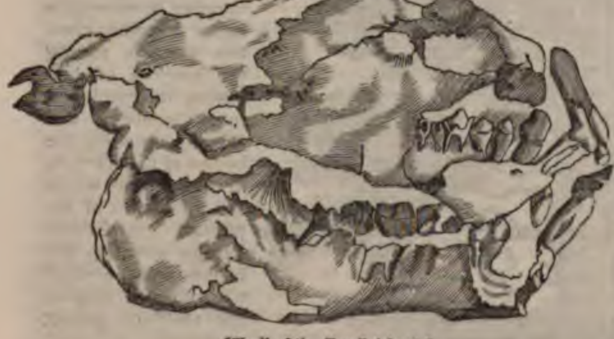
The only species is *Adansonia digitata*, the monkey-bread, sour gourd, lalo plant, &c., of the African negroes.



[Leaf and flower of Adansonia digitata.]

The leaves are deep green, and divided into five unequal parts, each of which is of a narrow, lanceolate figure, and radiates from a common centre. the outermost divisions being the smallest. The flowers grow singly in a pendulous position from the bosom of the leaves, are very large, white, crumpled at the edge, and have the petals very much reflexed. The stamens are very numerous, and are collected into a tube, which spreads at the top into a sort of umbrella-like head, from the midst of which arises a slender curved style, terminated by a rayed stigma. The fruit is an oblong, dull green, downy body, eight or nine inches long, containing several cells, in each of which there is a number of hard, shining seeds immersed in a soft pulp, which is scarcely juicy. From this pulp the negroes prepare an acidulous drink, much used in the fevers of the country. The bruised leaves, in a dry state, form a substance called *lalo*, which they mix with their food and imagine is useful in checking, or counteracting, the effects of profuse perspiration. Like the rest of the order, *Adansonia* is emollient and mucilaginous in all its soft parts.

ADAPIS, in zoology, the name of a genus of fossil pachydermatous (thick-skinned) mammals, described by M. Cuvier, in his great work *Sur les Ossemens Fossiles*, vol. iii. p. 265. The word is found in Gesner, as a synonyme of the common rabbit (not, as stated in the reference just given, of the *hyrax*), and is appropriated to the present genus, from the presumed similarity in size, organization, and habits, which probably existed between the latter animal and the fossil species.



[Skull of the Fossil Adapis.]

The remains, upon which M. Cuvier has founded the genus Adapis, the only specimen which he was able to procure during a period of twenty-five years devoted to researches after fossil bones, consist of three fragments of skulls, found in the plaster quarries of Montmartre, celebrated for the enormous quantity and variety of the remains of extinct animals which they have produced; and which, in the hands of M. Cuvier, nave effected such improvements in the kindred sciences of zoology and geology. The first of these fragments is a head, nearly perfect on the side imbedded in the mass of gypsum which contained it; and exhibiting the dentition nearly in a perfect form. The general outline of this skull closely resembled that of the hedgehog, but it was about one-third larger: there were four incisor teeth in each jaw, trenchant or edged and oblique; followed, on each side, by a canine tooth, of a conical form, but in other respects differing little from the molar teeth in length and figure. Of these latter, there appear to have been seven in each side of each jaw. The first of the upper jaw was trenchant; the second and third surrounded by a small ridge; and the remaining four flat crowned, as in ordinary herbivorous animals. In the under jaw the three first molars are pointed and trenchant, and the other four tuberculous, and similar to those which opposed them in the upper. Two other fragments procured by M. Cuvier,—one a portion of a lower, another of an upper jaw,—served to complete this description, by supplying some of the back teeth which were wanting in the more perfect specimen.

The few facts here reported, the only details which we at present possess concerning this extinct genus, are still sufficient to enable us to determine some of its most important affinities, and to assign its probable location in the system of natural beings. In fact, we only require to know the form of its feet and claws, to possess all the data necessary to determine its general conformation, as well as its habits and economy. The facts, already known, show us that this inhabitant of a former world must have belonged to that tribe of animals which M. Cuvier denominates pachydermata, from the great thickness of their skins, and which includes all hoofed quadrupeds that do not ruminate or chew the cud. Among recent, or existing animals, there are scarcely two dozen species appertaining to this group; and only eight different genera, all widely separated from one another, and without any of those intermediate forms and modifications, which, in other natural orders, unite the different genera by an almost imperceptible gradation of characters. The horse, the elephant, the rhinoceros, the hippopotamus, the tapir, the hog, all pachydermatous quadrupeds, have few characters in common; are allied to one another by no intermediate forms among the existing race of animals; and, in fact, appear to be rather the types of so many distinct and separate families, than the genera of one common order. This circumstance, so different from what is presented by all other tribes of animals, it was reserved for M. Cuvier to explain; and it is not a little singular that the fossil remains of animals which have long since ceased to exist, but which this truly great man has restored and characterised, should be precisely those which are wanting to complete the connexion among the existing genera of pachydermata. Of eighty extinct species of mammals discovered by M. Cuvier, and described in the *Ossemens Fossiles*, no fewer than fifty appertain to this order; thirty-eight of which belong to eleven distinct genera, which have no representatives among living animals. These serve to connect the existing genera of pachydermata with one another, and to complete that gradation of characters, which, before their discovery, was so imperfect in this order of animals. This abundance of pachydermata among the fossil remains of extinct animals, compared with the very small proportion which the existing species of this genus bear to the total number of animals actually inhabiting the globe, at the present moment, is a most remarkable and curious fact; whilst the singularity of their forms, and the number of new genera which have been established upon their different modifications, are extremely interesting; more particularly when we are told that, among all the fossil remains of other orders of mammals, no single fragment has been discovered to indicate the former existence of a genus different from those which subsist at the present moment.

ADAR, the twelfth month of the Hebrew year, as appears from Esther iii. 7: 'The twelfth month, that is the month Adar.' The name of this month is Chaldee, and does not occur in the earlier books of the Bible, where the months are usually designated by their numerical order.

In the Jewish Calendar, Adar is the sixth month. In ecclesiastical computations, it is still the last of the year. A year composed of twelve lunar months is shorter by about eleven days than a true year, and, if unaltered in length, would be perpetually changing the season of its commencement. To avoid this inconvenience, all nations using such a year (except the Mohammedans) occasionally insert an additional month, to bring the beginning of the year to the same season. The additional month in the Jewish Calendar immediately follows Adar, and is called Ve-adar. This intercalation occurs seven times in nineteen years.

Adar may begin as early as the 1st of February, or as late as the 3d of March: in 1833, it begins on the 20th of February. In years of twelve months there are twenty-nine days in Adar; in those of thirteen months, there are thirty days in the month.

A fast is observed by some Jews in memory of the death of Moses on the 7th day of the month; another on the 9th, for the schism in the schools of Shammai and Hillel. On the 13th day of the month, the fast of Esther is kept by the whole Jewish nation. This fast is said to have been instituted in memory of the intended destruction of the Jews in the Persian empire on that day (Esther, iii. 13). If the 13th day should be a Saturday, the fast of Esther is celebrated on the preceding Thursday; all other fasts (except the Great Fast of Expiation, which is never postponed) are, in similar cases, held on the Sunday following.

The Feast of Purim, which lasts two days, belongs to the 14th and 15th of the month, in memory of the defeat of the plans laid for destroying the Jews. This feast was celebrated in the mode and on the days appointed in the 9th chapter of Esther, verses 15—21. It is made 'a day of gladness and feasting, and a good day, and of sending portions one to another.' Two days were dedicated to this festival, because the slaughter of the enemies of the Hebrews ceased on those two days in the different provinces of the empire.

In the years in which the month Ve-adar is inserted, the Purim and the Fast of Esther belong to that month; and the 14th of Adar is called the First or Little Purim. It appears, then, that in the intercalary year, it is the first Adar that is really the intercalary month, as the festivals remain to Ve-adar. [See Ideler, *Lehrbuch der Chronologie, Berlin*, 1831.]

The festival in honour of the dedication of the second Temple, is kept by some Jews on the 16th, and by others on the 23d of this month. There is no exact account of the day of dedication; the Temple was completed on the 3d day of the month. Ezra vi. 15.

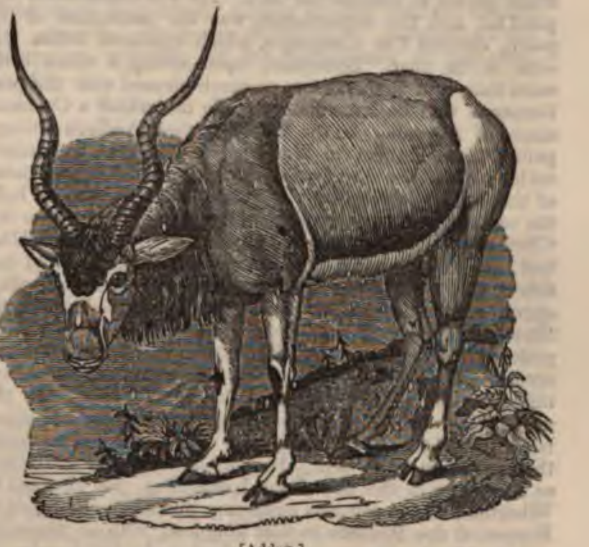
Adar is the name of the seventh month of the Syro-Macedonian year, which coincides nearly with our March.

ADDA, or **El Adda**, the Arabic name of a small species of lizard, celebrated by the eastern physicians on account of its pretended efficacy in the cure of elephantiasis, leprosy, and other cutaneous diseases, to which the Arabs and inhabitants of Egypt are peculiarly subject; and of which, according to Bruce, they are more afraid than of the plague itself. We are not informed of the manner in which these wonderful cures are effected; whether the living animal is applied externally, as toads have been to cancers, even in our own country, or taken inwardly in the form of a powder; but, in all probability, its reputed virtues, in either case, have no better foundation than those formerly attributed to the bezoars, rhinoceros-horns, and other animal substances, which composed such an important part of the pharmacopœia of the Arabian school of medicine.

The adda, as described by Bruce, is about six inches and a half in length; the body and tail are cylindrical, the latter thick at the base, and ending in a very sharp point; the head is conical, and the mouth provided with two rows of small feeble teeth; the face is covered with five black lines, which cross one another like a net: the body is a light straw colour, crossed with eight equi-distant bands of black, and the scales are so finely polished, that they almost appear as if they had been varnished. The adda is found in Arabia, Egypt, and Nubia; it is particularly abundant in the neighbourhood of the ancient Meroë (near the Nile about N. Lat. 17°); and, in short, throughout every part of the sandy deserts of Asia and Africa, wherever the slightest traces of moisture exist. 'It burrows,' says Bruce, 'in the sand, and performs the operation so quickly, that it is out of sight in an instant, and appears rather to have found a hole than to have made one: yet it often comes out during the heat of the day to bask itself in the sun; and, if not very much frightened, will take refuge behind stones, or in the withered, ragged roots of the absinthium, dried in the sun to nearly its own colour.'

ADDA, the Roman Addua, a river of Lombardy, which has its source in the Rhætian Alps above the town of Bormio; it waters the Valteline in its whole length, then enters the lake of Como, out of the south-eastern branch of which it issues again below the town of Lecco; it then crosses the plain of Lombardy, passing by Cassano, Lodi, and Pizzighettone, and falls into the Po about eight miles above the city of Cremona. It was by forcing the bridge of Lodi over this river, that Bonaparte won a decisive victory over the Austrians, 10th May, 1796. Again, on the 27th April, 1799, the French, under Moreau, were totally defeated at Cassano, on the banks of the Adda, by the Austrian and Russian armies. Before the fall of Venice, the Adda formed the boundary between the territory of that republic and the Duchy of Milan. It is a rapid and wide stream, affording a good military position, in advance of Milan on the east.

ADDAX, in zoology, a species of ruminating animal, called by the ancients Strepsiceros, from the spiral or twisted form of its horns. It was unknown to modern naturalists till the recent journey of the German traveller Rüppel, who discovered it on the barren sands of Nubia and Kordofan, where it still retains its ancient Arabic name of Addas or Abou-Addas. For a more particular account of this interesting animal, see Antelope.



[Addax.]

ADDER, a name of the common viper. See Viper.

ADDISON, JOSEPH. This eminent writer was the son of the Reverend Lancelot Addison, a clergyman of considerable learning, who eventually obtained the deanery of Litchfield, but was, at the time of the birth of his son, rector of the parish of Milston, near Amesbury, in Wiltshire. Here Addison was born on the 1st of May, 1672. After having been put first to a school in Amesbury, taught by the Rev. Mr. Nash, and then to that of the Rev. Mr. Taylor, at Salisbury, he was sent to the Charter-House, at which seminary he first became acquainted with his afterwards celebrated friend, Steele. From this school he went about the age of fifteen to Queen's College, Oxford, and removed to Magdalen College, upon obtaining a scholarship two years afterwards. He is said already to have obtained considerable facility in the writing of Latin verse; and this talent, which he continued to cultivate and exercise, first brought him into reputation at the university. Several of his Latin poems, most of which were probably produced before he had attained his twenty-sixth year, were afterwards published in the second volume of the collection entitled, *Musarum Anglicanarum Analecta.* The first composition which he gave to the world in his native language was a copy of verses addressed, in 1694, to Dryden, which procured him the acquaintance and patronage of that distinguished poet. He soon after published a translation in verse of part of Virgil's Fourth *Georgic;* and he had also the honour of writing the critical discourse on the *Georgics*, prefixed by Dryden to his translation, which appeared in 1697. But before this, Addison had made himself known to one of the most enlightened and influential patrons of literature in that day, the Lord Keeper Somers, by a poem which he addressed to him, on one of the campaigns of King William. He was also introduced by Congreve to the Chancellor of the Exchequer, Mr. Montague, afterwards Lord Halifax. The advantageous connexions which he had thus formed seem, together with other considerations, to have induced him to abandon his original intention of going into the church. In 1699 Lord Somers procured him a pension of 300*l.* a-year from the crown; and he then set out on a tour to Italy. Here he remained till the death of King William, in the spring of 1702, deprived him of his pension, and also put an end to his expectation of being appointed to a place near the person of Prince Eugene, then commanding the Imperial troops in Italy. Meanwhile he had addressed from that country his well known poetical *Letter* to Lord Halifax, which was greatly admired both in England and Italy, and was translated into Italian by the Abbate Salvini, Greek professor at Florence. Soon after his return home he also published his *Travels*, which he dedicated to Lord Somers. His friends being out of power, he now remained for some time without employment. But at length the victory of Blenheim, in August 1704, excited a wish in the ministers to find some poet who might adequately celebrate its glories; and the Treasurer Godolphin having mentioned the matter to Lord Halifax, the latter recommended his friend Addison as the fittest person to execute the task. He was immediately applied to; and the consequence was the production of his poem, entitled *The Campaign*, which appeared before the close of the year. Godolphin, upon seeing it when little more than half finished, was so much pleased with the performance that he immediately made the author a Commissioner of Appeals. In the following year Addison accompanied Lord Halifax to Hanover; and in 1706 he became under secretary to Sir Charles Hodges, on the appointment of the latter as Secretary of State. He continued to hold the same place under the Earl of Sunderland, by whom Sir Charles was in a few months succeeded. But although he had thus fairly entered upon a political career, he did not desert literature. His next production was his English opera, entitled *Rosamond;* and he also assisted his friend Steele in his play of the *Tender Husband*, not only with a prologue to the piece, but with several of its most effective scenes. In 1707 an able anonymous pamphlet appeared, under the title of *The present State of the War, and the necessity of an Augmentation considered*, which has since been printed among Mr. Addison's works, and was no doubt the production of his pen. In 1709 he went over to Ireland as Secretary to the new Lord Lieutenant, the Marquis of Wharton; the queen also bestowing upon him the office of Keeper of the Records in that kingdom, with an increased salary of 300*l.* He was in Ireland when the first number of the *Tatler* appeared on the 12th of April (o.s.) in that year—the happy idea of Steele, whose connexion with the publication Addison is said to have detected from an observation on Virgil which he had himself communicated to his friend. The active part which he immediately took in the conduct of this periodical work is well known. The change of ministry in 1710, by releasing him from his official duties, and allowing him to return to England, enabled him to make his contributions still more frequent. In the course of this and the following year, he is also understood to have contributed several papers to the political work, *The Whig Examiner*, which was started about this time in opposition to the famous Tory print, *The Examiner*, in which Swift exercised his powerful pen. These papers, which are five in all, are printed among his collected works. The *Tatler* terminated on the 2d of January, 1711; but on the 1st of March following appeared its still more celebrated successor, the *Spectator*, which was continued till the 6th of December, 1712, and of which during the whole of that time Addison was undoubtedly the chief support. The *Spectator* was followed by the *Guardian*, of which the first number was published on the 12th of March, and the 175th and last, on the 1st of October, 1713; and in this also his pen was actively employed. An anonymous pamphlet directed against the commercial policy of the ministry, and bearing the title of *The late Trial and Conviction of Count Tariff*, which appeared this year, is likewise believed to be Addison's, and has been printed among his works. The same year he acquired still greater fame than any of his former productions had brought him by his celebrated tragedy of *Cato*, which was received with extraordinary applause, both on the stage and when it issued from the press. It was played thirty-five nights in succession,—a run of popularity for which it was doubtless in part indebted to its political as well as to its poetical merits; and it was also translated soon after into French, Italian, Latin, and German. On the 18th of June, 1714, appeared the first number of a continuation of the *Spectator*, in which Addison also assisted, till its termination on the 20th of December in the same year. His elegant poetical address to Sir Godfrey Kneller on his picture of the king, also was published about this time. And on the 23d December, 1715, soon after the breaking out of the Rebellion, he commenced a periodical publication in support of the government, under the title of *The Freeholder*, which he continued without assistance at the rate of two papers a-week, till the 29th of June, in the following year. He had now indeed for some time been again engaged in public affairs, having, on the death of Queen Anne, in August 1714, been appointed their secretary by the Lords Justices; and after the coming over of the new king, having again gone to Ireland as secretary to the Lord Lieutenant, the Earl of Sunderland. The earl was soon after recalled, and Addison was then made a Lord of Trade. In 1716 he married the Dowager Countess of Warwick; and in April the following year he was nominated one of his majesty's principal secretaries of state. He soon, however, found it necessary to resign this high employment,—retiring professedly on the ground of ill health, but in reality, as has been generally understood, in consequence of his entire inaptitude both for debate in parliament and for the ordinary business of his office. It is related that his fastidiousness in regard to expression would sometimes so embarrass him in the preparation of an urgent dispatch, that he was obliged to resign the task to one of the clerks, in order that it might be expedited in time. His health, however, had also been for some time impaired by attacks of asthma,—the effects of which were probably in no slight degree aggravated by a habit of over indulgence in wine, to which he had long been addicted, but to which after his marriage he gave himself up more than ever, seeking refuge in its baneful excitement from domestic unhappiness. He left office in March 1718. It was hoped at first that his release from business would have brought about his restoration; and for some time the expected effect seemed to follow. In the course of the year 1719 he was so far recovered as to be able to engage in a somewhat acrimonious controversy with his old friend Steele on the subject of the bill for the limitation of the peerage, then under discussion in parliament, which Steele had attacked in a paper called the *Plebeian*. Addison's defence of the measure appeared in two successive anonymous pamphlets, bearing the title of *The Old Whig*. They are not printed among his collected works; but are undoubtedly his. He again, however, fell ill, and after lingering for some time, at last expired at Holland House, Kensington, on the 17th of June, 1719, when just commencing his forty-eighth year. He left a daughter by the Countess of Warwick.

Soon after Addison's death, his works were collected and published in four volumes quarto, by his friend Mr. Tickell, upon whom he had expressly devolved that duty. Besides the compositions already mentioned, and some translations from Ovid and other poetical pieces, this edition contains a treatise on ancient medals in the form of dialogues, which is understood to have been prepared by the author many years before his death; and a portion of a work which he had commenced in defence of the Christian religion, being that which is commonly known by the name of his *Evidences*. The comedy of the *Drummer*, or the *Haunted House*, which had been published anonymously in his lifetime, with a preface by Sir Richard Steele, was also soon after reprinted by Sir Richard, and declared to be Addison's. Two other performances have likewise been since attributed to him on somewhat insufficient evidence; the first, a dissertation in Latin on the most eminent Roman poets, which appeared, with an English translation, in 4to. in 1718; and the other a tract, entitled a *Discourse on Ancient and Modern Learning*, which was printed with his name in 1739, having been found, it was affirmed, among the manuscripts of Lord Somers. This enumeration comprehends all his published productions. Among the literary schemes which he is said to have formed, but did not live to execute, were a tragedy on the death of Socrates, an English Dictionary on the plan of that of the Italian language by the Academy della Crusca, and a metrical translation or paraphrase of the Psalms. It does not appear that any of these undertakings had been even begun.

Addison, however, has been charged with having been the author of a poetical translation of the first book of the *Iliad*, which was published in 1715 by Mr. Tickell, then his private secretary; and by which it has been said he intended to aim a covert blow at the popularity and success of Pope's *Iliad*, the first volume of which had then just issued from the press. The question of Addison's concern in this affair is of more interest in reference to his moral, than to his literary character. A story has been engrafted upon the circumstance to the effect that Pope, with whom he had been for some years in habits of intimacy and professed friendship, was so stung by what he conceived to be the duplicity and baseness of his conduct on this occasion, that he immediately broke off their intercourse; and never would be again reconciled to him. The celebrated character of Atticus, now inserted in the Epistle to Dr. Arbuthnot, is said to have been composed by Pope after this, and sent by him to his former friend. The clearest examination which this story has received will be found in a long and elaborate note in Dr. Kippis's edition of the *Biographia Britannica*, (vol. i., p. 86, &c.) which is known to have been contributed by Sir William Blackstone. The learned judge has undoubtedly sufficiently refuted many points in the common statement; but still it is certain that a coolness did arise between Addison and Pope not long after the appearance of Tickell's book, and there is also reason to believe that their separation was not unconnected with that somewhat injudicious and ill-timed publication. As for the authorship of the translation, however, it was probably Tickell's own.

The literary greatness of Addison in the estimation of his contemporaries probably stood upon somewhat different grounds from those upon which it is now usually placed. In his own day he was looked upon as a dramatist and a poet of a very high order; and appears to have been not so much admired for anything else as for being the author of *Cato*. That stately but frigid tragedy has long ceased to give the same pleasure, by its sonorous declamation and well-expressed common-places, which it seems to have afforded to our ancestors. The taste which then prevailed in poetry was the most artificial which has distinguished any age of English literature. The quality which chiefly drew admiration was a cold and monotonous polish—the warmth of genuine nature was accounted rudeness and barbarism. The return of the public mind to truer principles of judgment in such matters has been fatal both to the dramatic and to the poetical fame generally of Addison; and although his verses are still read with pleasure as the productions of an elegant and accomplished mind, they are not felt to possess any high degree of that power which we now look for in poetry. His glory is now that of one of our greatest writers in prose. Here, with his delicate sense of propriety, his lively fancy, and above all, his most original and exquisite humour, he was in his proper walk. He is the founder of a new school of popular writing; in which, like most other founders of schools, he is still unsurpassed by any who have attempted to imitate him. His *Tatlers*, *Spectators*, and *Guardians*, gave us the first examples of a style possessing all the best qualities of a vehicle of general amusement and instruction; easy and familiar without coarseness, animated without extravagance, polished without unnatural labour, and from its flexibility adapted to all the varieties of the gay and the serious.

ADDITION, from the Latin *addo* to *give to*, is the putting together of two or more magnitudes into one. In Arithmetic and Algebra it also signifies the most convenient method of doing this, so that the sum or collection of added quantities may be counted or reckoned in the same manner as the parts of which it was composed. The sign of this operation is +, which is generally pronounced *plus*, the Latin for *more*. Thus $a+b$ directs us to add the number denoted by b to that denoted by a, and represents the sum of a and b.

Addition of whole numbers in arithmetic is performed partly by memory, partly by the aid of the decimal system of numeration. [See NUMERATION.] The sum of every two numbers, each of which is not greater than 9, must be remembered; from whence the addition of such numbers as 28 and 9, 33 and 6, &c., can be performed in the head. The further process is the same in principle, whether the several quantities to be added together be tens, hundreds, &c., pence, shillings, &c., or any other denomination. Presuming that no reader will be ignorant of the ordinary methods, we will show the general principle for all cases in the following question, in which any line of headings may be taken:—

Hundreds. Shillings. Roods.	Tens. Pence. Perches.	Units. Farthings. Yards.
b	c	d
f	g	h
l	m	n

Add together d, h, and n, and if they be units, convert the sum into tens and units; if farthings, into pence and farthings, &c., meaning thereby, take the greatest number of tens out of all the units, of pence out of all the farthings, &c., in $n+h+d$, and write what is left under n. *Carry* (as it is called) the tens, pence, &c., to the next column on the left, and add successively m, g, and c to them, taking out the hundreds, shillings, &c., as the case may be, from the result, and writing the remainder only under m. Carry the hundreds, &c., to the next line on the left, and so on.

The addition of fractions is, in principle, as follows. We cannot immediately express the sum of one-half of a foot and one-third of a foot otherwise than by writing $\frac{1}{2}+\frac{1}{3}$ of a foot. But if we recollect that *one-half* is *three-sixths*, and one-third is *two-sixths*, it is evident that the sum of one-half and one-third is *five-sixths*. The rule, therefore, is:—reduce the various fractions to others of equal value, and having the same denominator (see DENOMINATOR), add the numerators, retaining the denominator: or, multiply every numerator by every denominator, except its own; add the results, which gives the numerator of the sum: multiply all the denominators together for the denominator of the sum. Thus, for—

$$\begin{array}{rl} \frac{2}{3} + \frac{3}{7} + \frac{4}{5} & \text{which is } \frac{199}{105} \\ 2 \times 7 \times 5 = 70 & \left.\right\} \\ 3 \times 3 \times 5 = 45 & \left.\right\} \text{Add} \\ 4 \times 3 \times 7 = 84 & \left.\right\} \\ \overline{199} & \text{numerator} \\ 3 \times 7 \times 5 = 105 & \text{denominator.} \end{array}$$

To add decimal fractions, arrange them so that the decimal points shall fall under one another, proceed as in common addition, and let the decimal point in the sum total be placed under the other decimal points:—

$$\begin{array}{rr} 2{\cdot}61 \quad & 14{\cdot}103 \\ {\cdot}04 \quad & 1{\cdot}04 \\ {\cdot}118 \quad & 118\phantom{{\cdot}000} \\ \hline 2{\cdot}768 \quad & 133{\cdot}143 \end{array}$$

To add algebraical quantities, write them all one after another, without changing any sign, and connect the terms, which before had no sign, with the rest, by the sign +. Thus $a+b$ and $a-2b$ added, give $a+b+a-2b$. This is the sum, which may be reduced to a simpler form, by observing that b subtracted twice and added once, is equivalent to b subtracted once, and that a is added to a. The expression then becomes $2a-b$.

When the quantities are fractional, the preceding rule follows the application of another similar to the rule in fractional arithmetic. Thus, for

$$\frac{a}{a+b} + \frac{b}{a-b} \text{ the sum of which is } \frac{a^2+b^2}{a^2-b^2}$$

$$\begin{array}{rl} \left.\begin{array}{r} a \times (a-b) = a^2 - ab \\ b \times (a+b) = ab + b^2 \end{array}\right\} & \text{Add} \\ \overline{a^2 - ab + ab + b^2} & \\ \text{or} \quad a^2 + b^2 & \text{numerator} \\ (a+b) \times (a-b) = a^2 - b^2 & \text{denominator.} \end{array}$$

For further information, see *Library of Useful Knowledge, Algebra*, pp. 4, 22; *Study of Mathematics*, pp. 15, 22.

ADDITION of RATIOS. A phrase which may, perhaps, at first, puzzle the mathematical student who reads old books, and which we therefore explain here. Take two ratios or proportions, say 3 to 7 and 5 to 9; the ratio of 3 × 5 to 7 × 9, or of 15 to 63 was formerly said to be the *sum* of the ratios of 3 to 7 and 5 to 9. Similarly the ratio of

25 to 4 was said to be *double* of the ratio, or the *duplicate ratio*, of 5 to 2; that of 125 to 8, *triple*, or the *triplicate ratio*, and so on. [See Ratio, Logarithm.] The sum of the first ratios in any more modern work would probably mean $\frac{3}{7}+\frac{4}{9}$; but the term 'sum of the fractions, would most likely be used in preference.

ADEL, the name of a portion of eastern Africa, which it is not possible to describe with much precision. The name of Adaiel is sometimes given to that part of the African coast which runs from the straits of Bab-el Mandeb, the entrance of the Red Sea, to the bay and town of Zeila; and the name of Adel, or the land of the Somaulis, is extended as far as cape Guardafui. The chief place of the Somaulis is Berbera, to which the Arabs cross over from Aden and from Mocha, between October and April, to purchase gums, myrrh, frankincense, slaves, camels, horses, mules and asses, for which they give in exchange Indian wares. The inhabitants of unknown districts in the interior send caravans to Berbera with ivory and gold dust; and this is now the only channel of communication between the interior of central and southern Africa and the S.W. coast of Arabia. The Somaulis, sometimes called Berberes, have, according to some accounts, long hair and an olive complexion, but, according to Valentia, woolly hair and a very black-skin, though they are not negroes. They possess ships of their own, and are active, enterprising merchants; some of them have settled at Mocha in Arabia. Zeila is in N. lat. 11° 18′, E. lon. 43° 3′; and this or Berbera is the best point from which a traveller could set out to explore the southern boundaries of the Abyssinian provinces, and the upper waters of the Bahr el Abiad; the caravan communications already existing through Hurrur, which borders on the territory of Zeila, and running westward towards the supposed sources of the Nile, would render an attempt to penetrate into the interior probably not very hazardous. The horns of the cows of Adel are said to be very large, and probably the animal may be akin to the Galla oxen which Salt saw in Abyssinia, and which are brought from the south. A species of large-tailed sheep exists in this country, and the hair is rough like bristles.—[Valentia—Salt—Malte-Brun.]

ADELUNG, JOHANN CHRISTOPH, the well-known German grammarian and universal linguist, was born at Spantekon, a village near Anklam in Pomerania, on the 8th of August, 1732. He received his first education at the town-school of Anklam, and at Kloster-Berge, near Magdeburg; and afterwards visited the university of Halle. In 1759 he was appointed a professor in the evangelical gymnasium at Erfurt: but he held this situation only till 1761, when, in consequence of a dispute with the Catholic town-magistrates about a point of difference in religion, he found himself under the necessity of leaving Erfurt. Adelung now went to Leipzig, where he continued to reside till 1787. He supported himself by literary labours, and chiefly by translations of valuable works of foreign literature. The number of volumes which he thus prepared for the press, and many of which he enriched with extensive additions of his own, is surprisingly great. Among them, his *Glossarium manuale ad scriptores mediæ et infimæ Latinitatis*, (Halle, 1772-84, 6 vols. 8vo.) founded upon the previous labours of Du Cange and Charpentier, deserves particular notice. Besides these numerous translations and compilations, Adelung found leisure to prepare his critical dictionary of the High-German language. (*Grammatisch-kritisches Wörterbuch der Hochdeutschen Mundart.*) The plan of this work had already been projected by Gottsched, whom death prevented from following it up (1766), and who left but scanty materials for its execution. Adelung now turned his whole attention to the language of his native country, and several valuable works (*Deutsche Sprachlehre für Schulen*, Berlin, 1781, 8vo., *Umständliches Lehrgebäude der Deutschen Sprache*, Leipzig, 1782, 2 vols. 8vo., &c.) were the result of the profound study which he gave to this subject. In 1787 Adelung was called to Dresden and appointed principal librarian to the electoral library there. The important documents for Saxon history and antiquities which were now under his care, attracted his attention, and induced him to publish several works of deep research on the history and ancient institutions of the state which he served. Soon, however, his old predilection for philological and linguistic inquiries returned, and he formed the plan of his *Mithridates*, a work which he intended should contain a succinct historical account of all the known languages of the earth, with a translation of the Lord's Prayer, given as a specimen of as many as could be procured. Death prevented him from carrying this vast project into execution. Adelung died on the 10th of September, 1806, only a few months after the first volume of the *Mithridates*, giving an account of the Asiatic languages, had appeared. The plan of the work was afterwards taken up by Johann Severin Vater, who completed the whole in four volumes.—[See the article 'Adelung,' by Ebert, in Ersch und Gruber's *Encyclopädie*, vol. i.]

ADEN, a town of Yemen, one of the great divisions of Arabia, on the coast of the Indian Ocean, and nearly due east of the entrance of the Red Sea, N. lat. 12° 40′. E. lon. 44° 48′. The town stands on the east side of a small peninsula, or rather island, which is connected with the mainland by a causeway on seven arches, through which the sea rushes at high-water. The great gulf formed by that part of the African continent terminating in Cape Guardafui, and the opposite coast of Arabia, is sometimes called the gulf of Aden. This town has declined from its former importance, but is still the chief mart for the gums brought from Africa by the Somaulis, and is also noted for good coffee. Salt (p. 106) describes the place as a wretched heap of ruins and huts, situated under a scorching climate and inhabited by an unhealthy looking race of Arabs: the lower classes are very depraved in their morals. On the north and west sides of the town there is a very steep mountain, on the highest pinnacles of which still stand some old towers, erected by the Turks. The former more prosperous condition of this place is shown by the large and deep cisterns excavated in the rock, lined with stucco, on the N.W. side of the town, to which the water was brought from a ravine in the mountain by a broad aqueduct that may still be traced. Salt saw another cistern entire higher up the mountain, and backed by some large masses of granite. Salt has given, in his 'Voyage to Abyssinia,' a small sketch of Aden, taken from outside the harbour, and also a map of 'Aden Back Bay.'

ADHESION. This term has generally been employed to denote the property by which two solids, a solid and a fluid, two solids and an interposed fluid, or two fluids, remain attached to each other when their surfaces are brought into contact. Adhesion, in some instances, may be considered as little if at all different from cohesion, and dependant upon the same cause, while, in other cases, it appears to be connected with, and probably to a considerable extent derived from, chemical affinity; when, for example, two surfaces of lead are pressed together, the adhesion resembles mere cohesion, it acts at insensible distances like that power, and no change of properties ensues in the metal. If, however, the surface of a piece of lead is put into contact with mercury, the two metals act upon and combine with each other, and an amalgam is produced by chemical affinity. There are other instances in which the adhesion is not distinctly to be referred to cohesion, and in which it certainly does not depend upon chemical affinity, as when a plate of glass adheres to the surface of mercury, or liquids rise in small tubes by capillary attraction.

Among the earlier attempts to determine the force of cohesion are those of Dr. B. Taylor, in a paper on magnetism (*Phil. Trans.* 1721). He performed various experiments to ascertain the force of adhesion between wood and water, by determining the force in weight required to separate them. He found it to be directly as the surface, and that a square inch of wood required fifty grains to raise it from the water.

M. Achard (*Berlin Memoirs*, 1776) made a vast number of experiments on the force of adhesion between plates of glass of different diameters, and many liquids, and upon the adhesion of twenty different substances with as many liquids. It had been supposed that adhesion was derived from atmospheric pressure, but M. Achard found that by varying the pressure no change occurred in the adhesive force of glass and water; and that the adhesion of fluids to solids was uniformly in the inverse ratio of the temperature. The diminution in the force of adhesion by increase of temperatures was attributed by Guyton de Morveau to the rarefaction of the fluid by heat, and the consequent reduction of points of contact in the same space

As the surfaces of the solids employed by Dr. Taylor and M. Achard must have been wetted by the liquids, it has been objected to their experiments, and especially by M. Dutour in the *Journal de Physique*, that they do not prove any adhesion between the solid and the liquid, but cohesion between the two portions of the liquid which have been separated. If this objection be valid, then those only can be considered as proper cases of adhesion, in which no particle of one substance remains with the other after the separation of their surfaces, as when glass is separated from mercury; M. Dutour found that a disc of glass 11 lines (French) in diameter adhered to mercury with a force of 194 grains.

M. Guyton published in 1777 in his *Elémens de Chymie*, a series of experiments on the force of adhesion between eleven metals and mercury; his method was as follows:—the metals were perfectly pure, circular, and one inch in diameter; they were all of the same thickness and suspended from a ring in the centre at the arm of an assay-balance and counterpoised; the plates were then applied to the surface of the mercury, which was changed in each experiment, and the weights required to detach them were as follows:—

	Grains.		Grains.
Gold	446	Zinc	204
Silver	429	Copper	142
Tin	418	Antimony . . .	126
Lead	397	Iron	115
Bismuth . . .	372	Cobalt	8
Platina	282		

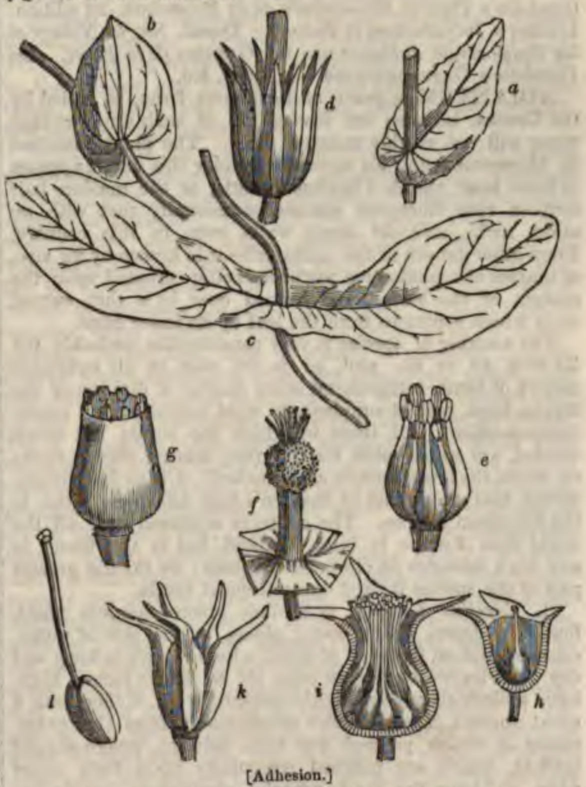
In these experiments the phenomena of adhesion appear to depend upon the degree of chemical affinity existing between the mercury and the metals applied to its surface. If the affinity be weak, the two surfaces will separate by the application of a slight force. Indeed, M. Guyton himself considers that the weight required to separate the different metals from mercury may directly express their affinity for it. It will be evident on a moment's consideration that the degree of adhesion is perfectly independent of the densities of the different metals.

The sixty-third volume of the *Philosophical Magazine* contains a paper by Mr. Bevan, in which the subject of adhesion appears to be considered in a point of view which had previously excited but little attention, viz., the real force of adhesion of different nails when driven into wood of different species; the weight, without impulse, necessary to force a nail a given depth into wood, and the force required to extract the same when so driven. The term adhesion in this case is applied to the force, whether arising from friction, or cohesion, or partly from both, with which wood resists the drawing out of a nail. Mr. Bevan has given a table of the adhesion, &c. of different kinds of nails when driven into dry Christiania deal; in this table it appears that a sixpenny nail, 73 to the lb., 2½ inches long, forced 1½ inch into the wood, required 327 lbs. weight to extract it; the percussive force required to drive the sixpenny nail to the depth of one inch and a-half into the dry deal, with a cast-iron weight of 6·275 lbs., was four blows or strokes falling freely, the space of 12 inches, and the steady pressure to produce the same effect was 400 lbs. With different kinds of timber the results varied greatly, and Mr. Bevan concludes that a sixpenny nail driven two inches into dry oak, would require a force of more than half a ton to extract it by steady pressure. Mr. Bevan (*Phil. Mag.* and *Annals of Philosophy*, vol. ii., p. 291) has also determined the force required to draw screws out of different kinds of wood; the screws used were about two inches in length, .22 diameter at the exterior of the threads, .15 diameter at the bottom, the depth of the worm or thread, being .035, and the number of threads in one inch = 12. These screws were passed *through* pieces of wood, exactly half an inch in thickness, and drawn out from the following dry woods by the annexed weights, beech 460 lbs., ditto 790 lbs., ash 790 lbs., oak 760 lbs., mahogany 770 lbs., elm 655 lbs., sycamore 830 lbs. The force required to draw similar screws out of deal and the softer woods, was about half the above.

ADHESIONS, Theory of, in Botany, is the basis of much of the philosophical part of that science, and forms one of the most striking points of difference between the doctrines of the present and preceding schools. It shows that many of the varied characters, which cause so endless a diversity of appearance in the vegetable kingdom, originate in the adhesion of a few very simple organs; and that what we are accustomed to consider parts of extremely different nature, only seem so in consequence of the way in which such adhesion occurs. Thus, the stem of a tree is not a homogeneous mass of vegetable matter, perforated by holes, or filled by little cavities caused by the extrication of air in it when in a soft state, but is produced by the adhesion of certain elementary bodies called Cellular Tissue, Fibrous Tissue, and Vascular Tissue (see ELEMENTARY ORGANS), arranged in a definite manner, which varies with species; neither is a leaf, or a fruit, or a flower a mere mass of pulp, or an expansion, like the horn of an animal, but also consists of these same elementary organs in a state of adhesion. To gardeners it has been long known that the property of adhesion between contiguous parts exists to a certain degree; for the operation of grafting or budding a portion of one plant upon another is dependent upon it. They also know that if two cucumbers, or two apples, or even two hard branches be artificially placed in contact when in a growing state, they will adhere, so as to become what may be called vegetable twins; and that the same phenomenon sometimes occurs constantly in certain cultivated plants, of which an instance is furnished by the cluster golden pippin apple, whose fruit is usually twin.

Guided by these well-known facts, modern botanists have discovered that the property of adhesion explains the true nature of every organ that plants bear, and that there is none so anomalous which cannot be shown to owe its appearance in a great measure to the union of contiguous parts. As it is very important that this should be clearly understood by all who make Botany their study, we shall proceed to give several illustrations of it.

Some leaves are said to be stem-clasping or amplexicaul, when their base partially surrounds the stem (*fig. a*); while some stems are said to be perfoliate, when they seem as if they pierced through the leaf, as in Bupleurum rotundifolium (*fig. b*); but the latter differ from the former only in this, that in the first the lobes at the base of the leaf embrace the stem without adhering, while in the second they not only clasp the stem but grow together where their margins come in contact. Some leaves are hollow, as in the pitcher plant, and these were formerly thought to be special organs with which no analogy could be discovered; they are now known to be leaves which have rolled up so that their opposite margins come in contact and adhere. Other leaves, growing from opposite sides of a stem, adhere in consequence of their bases becoming connate (*fig. c*), as in the honeysuckle; and finally there are others, many of which grow, in what botanists call a whorl, that is to say, all round a stem upon the same plane, and adhere by their margins into a sheath (*fig. d*), as in Casuarina.



[Adhesion.]

In other organs adhesions of a similar nature occur.

In the calyx all the sepals, or parts, are often distinct, as in the ranunculus; but they also often adhere by their edges, into a sort of cup, as in the cherry. Botanists used to consider the former as composed of many leaves, and the latter as composed of but one leaf, cut at the edge into a certain number of lobes. In the corolla the petals are either all separate, as in the rose, or they adhere by their edges into a cup or bell, as in the different heaths, Campanula, and the like; while the first was called many-petaled, the second were called one-petaled, it being thought, as in the case of the calyx, that it was a single petal of a special kind, cut into lobes at the margin.

Similar adhesions take place between the stamens. In the rose they are all distinct from each other; in the geranium they slightly adhere at the base (*fig. e*); in the mallow they adhere into a tube, except near the upper extremity, where they are not united, and have their ordinary appearance (*fig. f*); in other plants they grow together into a solid tube in which no trace of separation can be discovered, as in the genus Guarea (*fig. g*).

Finally, in the pistillum there are certain parts called carpella, each of which is a hollow body terminated by a style and stigma. These carpella are hollow, because they are formed of a flat organ doubled up so that its edges come in contact, and adhere to each other. Sometimes only one carpellum is present in a flower, as in the cherry (*fig. h*); sometimes several, as in the rose (*fig. i*). The adhesions in the latter case cause many of the differences we observe in the structure of fruits; for instance, an apple is composed of five such carpella, adhering to each other and to the calyx; an orange is composed of many such carpella, each of its lobes being one. In the nigella, the styles of the carpella are all distinct (*fig. k*), but in the lily and the myrtle (*fig. l*), the styles of the carpella adhere so completely that there seems to be but one. In the apple, the calyx seems to grow from the top of the fruit; this is caused by the carpella having at a very early period adhered to the inside of the calyx, which afterwards grows with their growth, and, finally, leaves its extremities in a withered state near the top of the carpella: in the cherry, on the contrary, no adhesion ever takes place between the carpellum and the calyx; and, consequently, when the fruit is ripe, there is no trace of the latter upon its upper end. In the raspberry, the fruit is enabled to slip like a thimble from off the receptacle, because the carpella all adhere by their sides.

For further information upon this subject consult De Candolle's *Théorie Elémentaire de la Botanique*, 2d edition. Lindley's *Introduction to Botany*. Dunal, *Sur la Nature et les Rapports de quelques-uns des Organes de la Fleur*. De Candolle's *Organographie Végétable*, &c.

ADIANTUM, a genus of dorsiferous ferns, so called by the Greeks, because the leaves are of such a nature that water will not readily moisten them. The plant described by Hippocrates and his successors under this name, appears to have been the A. Capillus Veneris, or the maiden-hair fern—a rare European species, occasionally met with on moist rocks, and old damp walls, even in this country. From other genera of the same tribe it is known by its size, or masses of reproductive particles, being situated upon the margin of the leaves, and carried over by a thin curved scale which separates from the leaf by its inner edge.

The number of species is very considerable, probably not far from 80 or 90, and, as is the case in all extensive genera of ferns, comprehend every degree of division of the leaves, from perfect simplicity to what botanists call supra-decomposition. All those in which the leaves are much divided, are remarkable for the very delicate elastic stalks on which the broad leaflets are attached; it is to this circumstance that the name of maiden's-hair has been given to the European species. The genus is scattered over all the world from Europe to New Zealand, but is not found in any high latitudes in either hemisphere; by far the greater part of the species inhabit damp tropical woods.

A. Capillus Veneris, is a dark green stemless plant, found in damp, sharp, rocky places, by the side of water-courses, and on the edge of wells, where the air is keen and dry. Its leaves, which are from six to fifteen inches high, have a blackish-purple, highly-polished stalk, divided into a great number of very slender ramifications, from the extremities of which proceed the thin, delicate, wedge-shaped leaflets, which are notched irregularly upon their upper edge, and have the most graceful appearance imaginable when growing a little above the eye, and gently agitated by the wind. Wonderful medicinal properties were once ascribed to this species, but they have long since been discovered to have no existence except in the exaggeration of fanciful practitioners. All that can be discovered in it is, a slight but pleasant aromatic flavour; the French occasionally use it in slight coughs. *Capillaire* is prepared by pouring boiling syrup upon the leaves of this species, or of *A. pedatum*, an American plant of larger growth and far less divided leaves; a little flavour is afterwards given with orange-flowers.

ADIGE, the Athesis of the Romans, called by the Germans Etsch, is a considerable river of North Italy, which has its source in the Alps of Tyrol above Brixen; it enters Italy by Bolzano and the valley of Trento, flows in a southern direction by Roveredo, parallel to and for the most part about 6 miles from, the lake of Garda, then turning abruptly towards the east, passes through Verona and Legnago; it afterwards enters the great Delta between the Brenta and the Po, and forming several branches, empties its waters into the Adriatic Sea. Below Verona it is from 3 to 500 feet wide; and from Legnago, its general course may be considered as parallel to that of the Po. It is a deep and rapid stream, dividing by its course the old Venetian territories from Lombardy proper. On its banks many a battle has been fought for the possession of Northern Italy.—[See ARCOLE.]

ADIPOCIRE. A substance so named from *adeps* fat, and *cera* wax, because it possesses the properties partly of fat and partly of wax; it is a body of a peculiar nature, being intermediate between fat and wax, and bearing a close resemblance to spermaceti. This name was given by M. Fourcroy in 1786, to the substance in question, which he discovered on examining a piece of human liver that had remained for ten years exposed to the air in the laboratory of M. Poultier de la Salle. In the same year Fourcroy had the opportunity of observing an accumulation of adipocire on a scale of prodigious extent, under circumstances of a peculiar nature, which are highly curious. There was in Paris an immense burial-ground, called La Cimetière des Innocens. This place had been the receptacle of the dead for a considerable part of the population of Paris for several centuries. On account of some improvements in the neighbourhood it was determined to remove this cemetery. The number of burials in this place had amounted to some thousands annually. The bodies were deposited in pits or trenches about thirty feet deep; each pit was capable of holding from twelve to fifteen thousand bodies; and as the pits became full they were covered with a few feet of earth. The extent of the whole area was about seven thousand square yards, and this space became at last occupied by a mass which consisted almost entirely of animal matter, rising several feet above the natural level of the soil. Scientific men were specially charged by the government to direct the precautions requisite for securing the health of the workmen in removing this immense mass of putrefying animal matter; among whom were Fourcroy and Thouret, the latter of whom has given a most interesting account of the circumstances attending the opening of the ground, and the former an analysis of the new and singular object that presented itself for investigation. The most remarkable change was found in the bodies that had been heaped together in the trenches. The first of these trenches opened in the presence of Fourcroy, had been closed for fifteen years The coffins were in good preservation; the covers being removed, the bodies were observed at the bottom, leaving a considerable distance between their surface and the cover, and flattened, as if they had suffered a strong compression; the linen which had covered them was slightly adherent to the bodies; beneath the linen was found nothing but irregular masses of a soft ductile matter of a grey-white colour, resembling common white cheese, the resemblance being more striking from the print which the threads of the linen had made upon its surface. The bones, which were surrounded by this matter, had no solidity, but were readily broken by sudden pressure. The head was environed with this peculiar matter; the face was no longer distinguishable; the mouth was disorganized; no trace remained of the viscera of the thorax and abdomen, which were all confused together, and converted into this fatty matter; and this was also invariably the case with the brain. None of this matter was found in bodies isolated from each other, but only in those accumulated in the common graves. From various observations it was found that this fatty matter was capable of enduring in these burying-places for thirty or forty years, but that ultimately it became corroded and was dissipated.

This substance, thus presented for examination under such remarkable circumstances, is considered by M. Fourcroy as an ammoniacal soap, formed of a peculiar oil combined with ammonia. Its properties are, that it melts at about 130° Fahrenheit; by a strong heat it is decomposed with the solution of ammonia. Alcohol acts but slightly upon it at common temperatures, but when boiling dissolves about one-fourth of its weight, the greater part of which separates on cooling in small acicular crystals. Lime, potash, and soda decompose adipocire with the solution of ammonia. It is decomposed by nitric acid with the production of nitric oxide, and by sulphuric acid with the development of charcoal. M. Chevreul (*Recherches sur les Corps gras*) finds that adipocire consists of a large quantity of margaric acid, and a small quantity of oleic acid, combined with a little ammonia, potash, and lime.

Different opinions have been entertained as to the nature of the operation by which adipocire is produced. From the experiments of Dr. Gibbes (*Phil. Trans.* 1794), it would appear that muscular flesh, when buried in moist earth, is, by a peculiar kind of decomposition, scarcely to be considered as putrefaction, converted into adipocire; and this change he found was expedited by exposure to running water.

M. Gay-Lussac has stated it as the opinion both of himself and M. Chevreul, that the apparent conversion of flesh into adipocire is merely a deception; and is nothing more than the wasting of the muscular fibres, while the fat remains. The experiments on which this conclusion are founded (*Ann. de Chim. et de Phys.* iv. 71) are these:—fibrin of blood was kept in water, renewed once every two or three days for three months; it all wasted way, and no fat whatever remained. Muscle of beef and liver being treated in the same way, some fatty matter remained. Dr. Thomson states that a body which had lain in a moss in Scotland for more than a century, was examined a few years since, and found to be entirely converted into a hard saponaceous matter; a portion cut from the thigh was chiefly adipocire; and the quantity of fatty matter was much too large to suppose it to have pre-existed in the living body. To this may be added another similar case observed by Sir E. Home and Mr. Brande, and published in the *Philosophical Transactions* for 1813.

By the action of dilute nitric acid upon lean flesh, Dr. Gibbes obtained a substance which he considered as exactly similar to the adipocire produced in the mode already described. Dr. Bostock (*Nicholson's Journal*, 8vo., vol. iv. p. 135) also formed adipocire by the agency of nitric acid; it is, however, most probable that the result of the action of the acid is essentially different from the true adipocire.

A'DIPOSE SUBSTANCE, *adeps*, fat. **ADIPOSE TISSUE**, *Tela adiposa*, Latin; *Tissu graisseux*, Fr.

Adipose substance, or fat, is an animal oil, which resembles, in its essential properties, the vegetable oils. It is wholly inorganic, though contained in an organized tissue. It varies in its consistence, or rather in the temperature at which it becomes solid. In general, it forms a pretty firm solid, constituting suet, which, when divested of the membrane in which it is contained, is called tallow; but there are animals in which, at the ordinary temperature of the atmosphere, it always remains fluid, as in the cetacea. At the temperature of the human body, it is fluid. It is therefore conceived, that during life it must exist in a fluid or semi-fluid state; though, when observed in the living body, as when incisions are made through the adipose membrane, either in the human subject or in animals, it appears as a soft, yielding, compressible substance, with a slight degree of translucence. There is reason, however, to conclude that this degree of firmness, as well as the general appearance which it exhibits in the living subject, is wholly derived from the organized membrane in which it is contained.

Human fat, when separated from the tissue in which it is deposited, is of a whitish-yellow colour, and the colouring matter, being soluble in water, is capable of being removed by washing. It is white and transparent in proportion to the youthfulness of the subject, the yellow colour increasing with age. When purified, it is perfectly white, inodorous, and of a mild, insipid taste. It is lighter than water, and burns with rapidity. By exposure to air and light it becomes rancid, and gives off a volatile acid, which has a strong odour. It is one of the few animal substances which does not contain azote; its ultimate elements are carbon, hydrogen, and oxygen. Bérard has succeeded in producing, artificially, a substance very analogous to animal fat. On mixing together one measure of carbonic acid, ten measures of carburetted hydrogen, and twenty of hydrogen, and transmitting the mixture through a red-hot tube, several white crystals were obtained, which were insoluble in water, soluble in alcohol, and fusible by heat into an oily fluid.

Until recently, it was conceived that fat is a simple principle, constituting one of the elements of the animal organization: but M. Chevreul, who has examined this substance with extraordinary diligence, has demonstrated that it is not a simple principle; but that it consists of two substances which are capable of being separated from each other, and obtained in a distinct form. Of these substances, one, at the ordinary temperature of the atmosphere, is solid; the other fluid. To the solid substance he gives the name of *stearine*, from στέαρ, fat or suet, and to the fluid substance *elaïne*, from ἔλαιον, oil. Stearine, the solid portion of fat, is a substance colourless, tasteless, nearly inodorous, soluble in alcohol, separable from this solution in the form of small, silky needles, and preserving its solidity at a temperature of 99° Fahrenheit. Elaïne, the oily principle of fat, is fluid at the temperature of 60° Fahrenheit; it is of a yellow colour, without odour, lighter than water, its specific gravity being 0·913, and easily soluble in alcohol. The difference in the fluidity, or the melting point of the fat of different animals, depends on the proportions in which these two substances are combined; in the more solid the stearine, in the less consistent the elaïne, being in excess.

The chemical processes by which these substances are obtained are simple. Adeps, tallow, or fixed oil, is dissolvable in very pure, hot alcohol; the stearine separates from the solution by crystallization, assuming the form, as has been already stated, of fine silky needles, while the elaïne is procured by the evaporation of the spirit. There is a still simpler process. Fixed oil is congealed by a low temperature; the mass is then pressed between folds of bibulous paper; the elaïne soaks into the bibulous paper, and the stearine remains in a separate form; when the bibulous paper is pressed under water, the oily matter which escapes is pure elaïne. The changes that take place when the constituent principles of fat combine with an alkali, as potash, will be explained in the article SOAP.

Animal fat is contained in a distinct membrane, termed the adipose tissue. The adipose is formed of the CELLULAR TISSUE, but the arrangement of the fibres is widely different in the former and the latter. The fibres of the adipose tissue are larger and tougher than those of the cellular, and form a much coarser web.

According to the most eminent anatomists, the structure of the adipose tissue consists of rounded packets, separated from each other by furrows; each packet is composed of small spheroidal particles; each particle is again divisible into still smaller grains, which present the appearance of vesicles, or minute bags or sacs, and it is in these bags that the fat is contained. The knife of the anatomist cannot indeed demonstrate the membranous walls of these adipose vesicles; but, though too fine and delicate to be distinguished by the eye, there is reason to conclude that the adipose tissue forms sacs which are completely closed, and that it is so arranged as to render each vesicle a distinct bag, having no communication whatever with any other vesicle. For, if a portion of the adipose tissue, recently taken from the body, be placed in warm water, of a temperature greater than is sufficient to melt the fat, not a drop of oil will escape, provided the temperature of the water be not sufficient to injure the membrane; but if incisions be made through the tissue, the oil instantly begins to issue from it; showing that the walls of the oil bags are divided, and that consequently the oil flows out. Again, though fat be fluid at the temperature of the human body, yet the adipose masses preserve a constant and definite form, which could not be the case unless the oil were inclosed in a solid sufficiently dense and resisting to maintain that form. Lastly, in however large a quantity the fat may be accumulated in any part of the body, it cannot by any degree of pressure be made to pass from one part to another; while the facility with which the cellular membrane permits the transmission of fluids through its cells from one extremity of the body to the other, is one of the most striking characters of that tissue. Neither in the fullest distension of the cellular tissue with fluid does a single particle ever penetrate the adipose vesicles; they never contain anything but their own proper substance.

There is reason to believe that the fat is immediately formed out of the blood, without any glandular apparatus for secreting it, by the capillary arteries of the adipose vesicles. In the furrow between each packet is placed the branch of an artery and vein. These vessels divide and subdivide to an extreme degree of minuteness, penetrating and terminating in the vesicles of which the packet is composed. In these vesicles the ultimate or capillary arteries, by a process, the nature of which is wholly unknown, separate adipose matter from the blood which is flowing in them, and deposit it in the vesicles. By chemical analysis, the materials of fat, like those of all the other secretions, are found to be contained in the blood; but in what mode the fat is separated from the blood we are wholly ignorant. It is probable, however, that the blood receives the oily principle of fat from the chyle, which is the nutritive matter formed by the process of digestion, in which it is ascertained to be present in large quantity.

As diffused over the body, the adipose membrane consists of masses which vary considerably in their magnitude and shape. In some places they are rounded, in others pear-shaped, and in the median line of the abdomen, egg-shaped. The distribution of the membrane is exceedingly unequal. There is, in general, a considerable layer immediately beneath the skin; and especially between the skin and the abdominal muscles, where it occasionally accumulates in enormous masses. Between the folds of the membranes which form the OMENTUM and MESENTERY, there is usually a large quantity; also around the heart and the kidneys; on the face, and especially on the cheeks, and in the orbits of the eyes; in the palms of the hands, the soles of the feet; the pulp of the fingers and toes, the flexures of the joints, the fibres of muscles, and the sheath of vessels. In most of these organs it never entirely disappears, whatever be the degree of leanness to which the body may be reduced; while in the cranium, the brain, the eye, the ear, the nose, and several other organs, there is none, whatever be the degree of corpulency.

The function which the adipose substance performs in the animal economy is not very apparent. Being a bad conductor of caloric, it cannot have much influence (though the fat immediately beneath the skin may have some) in maintaining the heat of the body, since the chief portion of it is situated deep in the system, and is placed around the internal viscera. Yet, it certainly accomplishes more than one purpose of no slight importance. 1. In the first place, it is probable that its accumulation in the system serves as a reservoir of inflammable matter for the generation of animal heat, and that it often actually maintains a process of combustion no less than the oil of the lamp. The phenomena of life present nothing more curious and interesting than the provisions which are made for the production and support of animal heat, as will be fully shown hereafter. (See HEAT, ANIMAL.) Animal heat is generated by the union of the carbon of the blood with the oxygen of the air, and the consequent formation of carbonic acid, the evolution of heat invariably attending the formation of this acid. By the process of digestion chyle is formed; chyle contains a large portion of carbon: this carbon is poured into the great venous trunks of the system, and, in a mode which will be explained hereafter, is immediately carried to the lungs by the great vessel that springs from the right heart. In the lung it is consumed, in the formation of carbonic acid gas, for the production of animal heat; and the large supply required for the continual maintenance of this process is, under ordinary circumstances, afforded by the chyle. But suppose this supply to fail; then immediately the absorbent vessels take up, from its various receptacles, the adipose matter accumulated in the system, and convey it to the veins; the veins transmit it to the lung, and thus the lung is supplied with the necessary quantity of carbon for the generation of carbonic acid, and the consequent production of animal heat. 2. In the second place, it serves a most important use in obviating the effects of excessive nutrition. When too much food is taken, or when the secretions and excretions are suppressed, grievous evils would arise, and often death would ensue, if there were no provision for the removal of this superfluous matter. One of the most important of these provisions is the deposition of fat, by which the system is lightened of a burthen; and the circulating system especially is relieved of a fulness and tension of its vessels, which might induce in them a fatal state of action. The secretion of fat from the blood, and the deposition of it in its various receptacles, is thus one of the safety valves of the constitution. The generation of it under circumstances favourable to its formation, that is, under circumstances which put the system in danger, either from the quantity or the quality of the blood, is extremely rapid. In man, no other solid is ever formed as quickly as this sometimes is; but in some animals, in certain states of the atmosphere, a prodigious accumulation of it is said to take place in the course of a few hours. Bichat states that during a fog of twenty-four hours continuance, thrushes, wheat-ears, ortolans, and red-breasts, are sometimes observed to become so fat that they are unable to fly from the sportsman.

A certain quantity of fat is a sign and an effect of health; an excessive accumulation of it is a sign and a cause of disease. The quantity actually generated is influenced by a great variety of circumstances. 1. By age. At the two extremes of human life the quantity is always small. Before birth, it is less than at any other period. During the first half of fœtal existence, there is no appearance of it whatever. About the fifth month it begins to appear in isolated grains under the skin. At the period of birth, it is sometimes accumulated in considerable quantity; but even then, it is in distinct masses in no part of the body excepting beneath the skin; in the internal organs, and in every other part of the body, it is found only in small and separate grains. As the period of maturity passes into that of declining age, it is sometimes very abundant; but as old age advances, the quantity invariably diminishes; and in extreme old age it is very minute: this is one of the chief causes of the thinness so characteristic of this stage of existence. It is remarkable, too, that the situation of the fat in the aged is exactly the reverse of that in the infant. In the infant, as we have seen, there is scarcely any of this substance in the interior of the body, but almost all of it is accumulated immediately beneath the skin; and this is the cause of the plumpness and roundness of the external surface of the infant: in the old, on the contrary, whatever portion of fat remains in the system is almost all deposited in the very substance of the organs, while there is scarcely any on the external surface. 2. The quantity of fat is materially influenced by sex. In general, it is more abundant in the female than in the male. 3. By constitution. There are persons who never become fat at any period of life, however sound the health, however good the appetite, however favourable the circumstances for the formation of this substance. And this habit is often hereditary, being received from the parent and transmitted to the offspring for many successive generations. 4. By diet. Nutritious and abundant diet, consisting especially of animal food and malt liquors, conduces to its formation in large quantities; while high seasoned, spiced, or acid aliments, together with the immoderate use of spirituous liquors, check its production. 5. By the condition of the function of assimilation. If the power of assimilation (that is, the power of converting chyle into blood) be diminished, while the appetite remains unimpaired, a large quantity of chyle is flowing in the circulating stream which cannot be transformed into proper nutriment: this unassimilated, and therefore useless and pernicious chyle, is deposited in the adipose tissue, in the form of fat, and in this manner the circulation is relieved of its load. An excessive accumulation of fat in persons otherwise in sound health should therefore always excite attention; it is often the earliest indication of a diminution of the vital energy, and not, as is often supposed, a sign of vigorous health. 6. By the state of the secretions and excretions. Suppression of the ordinary secretions and excretions leads, in a way which can now be readily understood, to a corresponding and a compensating deposition of fat; while a preternatural increase of the natural evacuations, as in cholera, diarrhœa, diabetes, &c., and a preternatural increase of the discharge from the mucous surfaces, especially from those of the lungs and intestines, will prevent the deposition, and even cause the absorption of the adipose substance. 7. Active and long-continued physical exercise. Walking, running, riding, whatever species of exertion promotes the secretions and excretions, prevents the deposition of fat, as is exemplified in boxers, jockeys, and all who go through a regular system of training, of which vigorous exercise always forms a part. 8. Long-continued and intense mental exercise. Persons whose minds are acute, active, and vigorous, are seldom fat. There is no more certain or powerful means of becoming and keeping thin than hard and continuous mental labour. Among the conditions observable in all the remarkable instances on record of persons who have changed rapidly from a state of enormous obesity to a state of moderate thinness, vigorous mental exertion is one. Persons oppressed with an accumulation of fat, and accustomed to lead an indolent and luxurious life, when placed under circumstances which require great mental exertion, are invariably found to lose many pounds of their weight in a short time, and to undergo a sensible change in their general aspect; and this is owing chiefly to the absorption of the adipose substance. 9. But the accumulation of fat is influenced still more by the character than by the mere activity of the mental state. Cheerfulness and serenity of mind are highly conducive to the deposition of fat, while anxiety of mind not only suspends all further deposition, but causes an active absorption of it. The immediate cause of a sudden change from fatness to leanness is the absorption of the adipose substance. Thinness, too, is usually and justly thought to be the general accompaniment of a sour, fretful, and irritable temper. 10. Excessive sleep, together with the absence of physical and intellectual exertion, and still more, of mental anxiety, is highly conducive to the accumulation of fat. 11. Organic diseases, especially those which impede the formation of chyle, or which impede the conversion of it into blood, diminish the secretion of fat; hence persons who labour under organic diseases of the stomach and of the small intestines are invariably thin, and generally emaciated. This is also the case with those who are afflicted with diseases of the respiratory organs, such as the deposition of tuberculous matter in the lungs, by which the air-cells are choked up, and the air is prevented from coming into contact with the venous blood, and with the chyle contained in it. As the tubercles enlarge, the respiratory portion of the lung diminishes, and part after part of the organ being thus successively obliterated, the emaciation at length becomes extreme. 12. But even long-continued disorder of the system, without any organic disease, generally occasions wasting of the body, from the absorption of the adipose substance; because, in this state of the system, the processes of waste are more active than those of supply. 13. Long and intense heat, whether natural, as during hot summers, or artificial, as the heated temperature produced about furnaces, hot-houses, &c. and, lastly, long-continued abstinence, tend to diminish the quantity of fat.

Sometimes the accumulation of fat is enormous. The average weight of the human body, when well nourished, and of a medium size, is about 160 pounds, or between eleven and twelve stone; yet instances are on record of its attaining, by the deposition of fat, the weight of from thirty-five to forty stone. Dr. Cheyne mentions a case in which the weight was 448 pounds, equal to thirty-two stone. In the Philosophical Transactions are recorded two cases, in one of which the weight was 480 pounds, and in the other 500 pounds. The Breslau Collections contain two other cases, in one of which the weight was 580, and in the other 600 pounds. The inconveniences produced in the system by these enormous accumulations of fat, and the means to be adopted for preventing and removing them (for they can be prevented, and even removed, with absolute certainty, provided the health be in other respects sound), will be treated of under the term Obesity.

ADIT. [See Mining.]

A'DJECTIVE, in Grammar, the name of one of the parts of speech, or one of those great classes into which, for the sake of convenience, grammarians have distributed the words of a language. The term *adjective*, which is of Latin formation, signifies something that *adds to* precision in describing the nature of any object of which we are speaking. An adjective, in our language, is most commonly prefixed to the name of some thing, in order to mark some quality by which it is distinguished from other things belonging to the same class; thus, a *bad* man, a *good* man, a *fat* man, a *troublesome* man, &c.; a *black* horse, a *white* horse, &c. Here the terms *man* and *horse* are the most general or abstract (see Abstraction) terms by which we can express the idea of man or horse; but, by prefixing to them such adjectives as *bad*, *good*, &c., we limit, in some degree, the class of which we are speaking. Thus, when we speak of a *white* man, we exclude the consideration of black men, or men of any other colour. In like manner, when we say an *English* man, we limit the signification still further; and in this way we may descend to a Cheshire man, a Chester man, until we come to individuals indicated by a common name, such as Thomson, Smith, &c. By the aid of other words prefixed, such as John, William, &c., we at last come to some certain individual. It appears, then, that in the expressions John Page, William Smith, &c., John and William may have the names of adjectives as well as the words *black*, *white*, &c. And this leads us to observe that frequently *nouns* or names of things can be used like adjectives; thus we can say, a *silver ring*, a *gold stick*, *salt water*, *sea water*. Many words in English are, in fact, used both as nouns and adjectives. In the expression 'John's book,' *John's* may be considered as an adjective for the reasons just given. Some grammarians have wished to introduce the term *adnoun* instead of *adjective*, but though the word *adjective* is not a very good name, *adnoun* is no better.

There are two ways in which an adjective can stand in a proposition: we can say 'the horse is bad,' or 'a bad horse.' In the first example, *horse* is called the 'subject,' *is* the 'copula,' or connecting link, and 'bad' is the 'predicate' or qualifying term. According to the true idiom of our language, an adjective can stand at the end of any simple proposition, as, he walks *slow*, he rides *quick*, he speaks *loud*. It is true that usage is now beginning to be opposed to this mode of expression, and the adverb in *-ly* is gaining ground; yet there are cases where it is not possible to use the termination in *-ly* without making the spoken language at least very stiff and formal. Some words are used both as adjectives and adverbs.

Many adjectives are simple *roots*, such as *good*, *bad*, *hot*, &c., while others are formed by adding an affix or suffix to a noun.

The following list of adjectives formed by affixes, or by adding a complete word, belong to the Saxon part of our language:—

glad-some
play-ful
weight-y
wood-en
care-less
child-ish
fore-most
fork-ed
for-ward
god-like
man-ly
out-er

The following terminations are of Latin and Greek origin

act-ive
passion-ate
adamant-ine
sulphur-ic
angul-ar
duc-tile
coher-ent
attend-ant
habit-able
aud-ible
luc-id
autumn-al
period-ical
station-ary
transit-ory
Belgi-an
humor-ous
verb-ose

There are other terminations of less importance, such as *ether-eal*, *advent-itious*, &c., which agree with the examples already given, as to the *last* syllable, but differ in having an additional syllable or syllables between the first part of the word and the termination.

ADJUSTMENT, in marine insurance, is the settling and ascertaining the exact amount of indemnity which the party insured is entitled to receive under the policy, after all proper allowances and deductions have been made; and fixing the proportion of that indemnity which each underwriter is liable to bear. The contract of insurance is an agreement to indemnify the insured against such losses as he may sustain by the occurrence of any of the events which are expressly, or by implication of law, contained in the policy. Thus, when a ship is lost, or any of those contingencies arise against which the insurance provides, the owner of the ship or of the goods insured, as the case may be, or an authorized agent, reports the circumstance to the insurers or underwriters. In London, this notice is given by an insertion in a book kept at Lloyd's Coffee-House in the subscription-rooms, where the greater part of marine insurances are effected.

Before any adjustment is made, the underwriters require to be informed of all particulars, that they may be satisfied the loss has occurred through circumstances against which the insurance was effected. In ordinary cases the task of ascertaining these facts, and of examining the correctness of the demand made by the assured, rests with the underwriter who has first subscribed the policy. In complicated cases of partial, or average losses, the papers are usually referred to some disinterested party, who makes a profession of such references, to calculate and adjust the per centage rate of loss. Where the ship is wholly lost, of course little difficulty occurs in this part of the inquiry; but in cases of partial losses, where the insured has not exercised his right of abandonment (see ABANDONMENT), very minute and careful examination often becomes necessary. The quantity of damage being ascertained, the amount which each underwriter has made himself liable to by subscribing the policy is settled; and this being done, it is usual for one of the underwriters, or their agent, to indorse on the policy, 'adjusted a partial loss on this policy of so much per cent.' To this indorsement the signature of each underwriter must be affixed, and this process is called the adjustment of the loss.

After an adjustment has been made, it is not usual in mercantile practice for the underwriter to require any further proof, but at once to pay the loss; and it has been said that the reason for which adjustments have been introduced into the business of maritime insurance is, that upon the underwriter signing an adjustment, and thereby declaring his liability, and admitting that the whole transaction is adjusted, time should be given him to pay the money. As a question of law, however, it is undecided how far the adjustment is conclusive and binding upon the underwriters; the better opinion appears to be that the adjustment is merely presumptive evidence against an insurer, and has only the effect of transferring the burden of proof from the assured to the underwriters; that is, where an adjustment has taken place, and the liability to pay the loss is disputed, the adjustment alone, without further proof, will be sufficient to entitle the insured to recover in an action on the policy, unless the under-writer shows facts which may have the effect of relieving him from liability. It is much to be lamented that a question of such importance in commercial transactions should not have received a solemn decision.—[See Selwyn's *Nisi Prius*, title *Insurance*; Park, on the *Law of Marine Insurance*, and a note to Campbell's *Nisi Prius Reports*, vol. i., p. 276.]

ADJUTANT, a military officer, attached to every battalion of a regiment. The office does not confer a separate rank, but is usually given to one of the subaltern officers. The duties of an adjutant are to superintend (under the major of the regiment, and the adjutant-general of the army) all matters relating to the ordinary routine of discipline in the regiment; to receive and promulgate to the battalion all general, garrison, and regimental orders, signing them in the orderly-book on the part of the commanding-officer; to select detachments from the different companies, when ordered; to regulate the placing of guards, distribution of ammunition, &c.

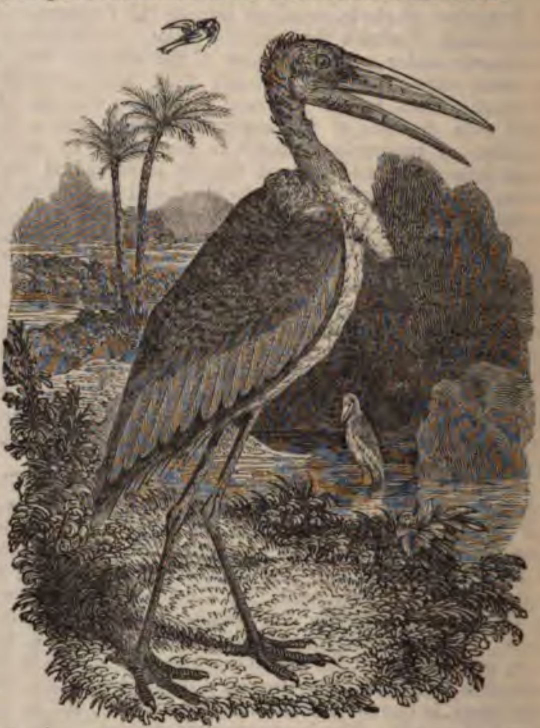
ADJUTANT-GENERAL, a staff-officer, one of those next in rank to the commander-in-chief. He is to the army what the adjutant is to a regiment; he superintends the details of all the dispositions ordered by the commander-in-chief, communicates general orders to the different brigades, and receives and registers the reports of the state of each, as to numbers, discipline, equipments, &c. Though in a large army, the adjutant-general is usually a general officer, yet this rank is not necessary; and in smaller detachments acting independently, the duties are frequently entrusted to an officer of lower rank.

ADJUTANT-GENERAL. Among the Jesuits, this title was given to certain fathers who resided with the general of the order. It was their duty to furnish him with information as to what was going on in the different countries of Europe, which was effected by means of emissaries employed for that purpose. Each country had one of these officers attached to it.

ADJUTANT, or GIGANTIC CRANE, (*Ciconia argala*, TEMMINCK, *Mycteria argala*, VIEILLOT.) A singular bird, not uncommon in travelling menageries, being easily tamed, and hardy, though a native of the warmer parts of India and found near Calcutta. Its size may be inferred from the fact of its wings, from tip to tip, measuring about fourteen or fifteen feet when stretched out; from the tip of the bill to the extremity of the claws it is seven feet and a half, while it is five feet high when standing erect. Its upper parts are ash-grey, the feathers there being stiff and hard; the under parts are white, and there the plumes are long; the head and neck are without feathers, but the red callous skin there is furnished with hairs; a long slightly downy conical bag or pouch, like 'a large sausage,' (to use the comparison of Baron Cuvier) hangs from the middle of the neck. The beak is very large, thick at the base, and the gape is very wide.

Though this does not rank in systematic classifications as a bird of prey, being properly placed with wading birds (*Grallatores*, ILLIGER), it is one of the most voracious and carnivorous birds known. The structure of its digestive organs corresponds with this voracious habit; though what comparative anatomists term the solvent or gastric glands are differently formed from those of any other bird. Their usual position in other birds is round the upper portion of the stomach; but in the adjutant they form two circular figures, about an inch and a half in diameter on the fore and back part of it, each gland being composed of five or six cells, and these opening into one common pipe (*ductus*). The gizzard and digastric muscle are nearly of the same strength with those of the crow, the gizzard being lined with a similar horny membrane.

The adjutant is not only capable of digesting bones, but it seems to be fond of them, swallowing every bone which it can get down its gullet,—a circumstance which has led to its being called the *bone-eater*, or *bone-taker*. It has been stated by Sir Everard Home, that there was found in the craw or stomach of a gigantic crane a land tortoise ten inches long, and a large male black cat entire. [*Ives' Voyage*, p. 184. *Phil. Trans.* 1813, p. 77.] Its great voracity, however, is extremely useful in the countries which it inhabits, as it collects vermin from every quarter, such as snakes, lizards, frogs, and other reptiles, devouring such immense numbers of these as to prevent them from annoying the inhabitants, who, on that account, hold the bird in as great estimation as the Hollanders do the stork.



[Adjutant, Ardea Gigantea. From a specimen in the Zoological Gardens.]

Mr. Smeathman furnished Dr. Latham with an interesting account of the adjutants from personal observations in India. 'They are,' says Dr L., 'met in companies; and when seen at a distance, near the mouths of rivers, coming towards an observer, which they often do with their wings extended, may well be taken for canoes upon the surface of a smooth sea—when on the sand-banks, for men and women picking up shell-fish or other things on the beach. One of these, a young bird about five feet high, was brought up tame, and presented to the chief of the Bananas, where Mr. Smeathman lived; and, being accustomed to be fed in the great hall, soon became familiar, duly attending that place at dinner-time, placing itself behind its master's chair frequently before the guests entered. The servants were obliged to watch narrowly and to defend the provisions with switches; but, notwithstanding, it would frequently seize something or other, and once purloined a whole boiled fowl, which it swallowed in an instant. Its courage is not equal to its voracity, for a child of eight or ten years old soon puts it to flight with a switch, though at first it seems to stand on its defence, by threatening with its enormous bill widely extended, and roaring with a loud voice like a bear or tiger. It is an enemy to small quadrupeds, as well as birds and reptiles, and slily destroys fowls or chickens, though it dares not attack a hen openly with her young. Every thing is swallowed whole; and so accommodating is its throat, that not only an animal as big as a cat is gulped down, but a shin of beef broken asunder serves it but for two morsels. It is known to swallow a leg of mutton of five or six pounds, a hare, a small fox, &c. After a time the bones are rejected from the stomach, which seems to be voluntary, for it has been known that an ounce or two of emetic tartar given to one of these birds produced no effect.’ [*Gen. Hist. of Birds*, ix. 40, 41.]

Lord Valentia (now Lord Mountnorris), after mentioning the amazing flocks of kites and crows which abound on the house tops and in the gardens at Calcutta, and subsist on the remains of the great profusion of food there dressed, which the prejudices of the natives forbid them to touch, adds, that in the office of scavengers the kites and crows are assisted during the day by the adjutant bird, and at night by the foxes, jackals, and hyænas from the jungles in the vicinity. [*Trav.* i. 519.]

Ives calls the bird a monster; but says the natives reverence it so much that they were rejoiced when he was unsuccessful in shooting one. They believe, according to the strange doctrine of transmigration, that the souls of the Brahms possess the birds, and render them invulnerable. [*Ives' Voyage*, London, 1773, p. 183.]

ADMINISTRATION and ADMINISTRATOR. An administrator is a person appointed by the ordinary or bishop of the diocose to make administration of, or to distribute the goods of a person who dies without having made a will. It is said that, in very early times, the king was entitled in such a case to seize upon the goods in his character of general trustee of the kingdom, in order that they might be applied to the burial of the deceased, the payment of his debts, and to making a provision for his family. It would appear that this power of the crown over the effects of intestates was greatly abused, for, by Magna Charta, King John granted that ‘if a freeman should die intestate, his chattels should be distributed by the hands of his near relations and friends, under the inspection of the church.’ This, probably, formed the foundation upon which the prelates afterwards built their right to administer by their own hands the goods of an intestate. There is, at all events, no doubt of the fact, that the power of seizing the goods of an intestate was, at a later period, transferred from the crown to the bishops. The whole property was, in the first instance, placed in the custody of the ordinary, or bishop of the diocese in which the intestate died; and after the deduction of what were technically called ‘*partes rationabiles*,’ that is, two-thirds of the whole, which the law gave to the widow and children, the remaining third part vested in the bishop upon trust to distribute that proportion in charity to the poor, or in what were then termed ‘pious uses,’ for the benefit of the soul of the deceased. This trust was greatly abused by the prelates, who unscrupulously converted the whole residue of the property to the use of their order, without even paying the just debts of the deceased. To remedy this injustice, the statute called ‘the Statute of Westminster the Second,’ which was passed in the reign of Edward I., provided that the debts of the deceased should be paid by the ordinary in the same manner as if he had been an executor appointed by a will. The remainder, after payment of debts, still continued applicable to the same uses as before. To prevent the abuses of the power thus retained by the ordinary, and to take the administration entirely out of his hands, the legislature again interposed, and by the statute of 31st Edward III., cap. 2, the ordinary was directed, in case of intestacy, to depute ‘the nearest and most lawful friends’ of the deceased to administer his goods; and these *administrators* are put upon the same footing with regard to suits and to accounting, as executors appointed by will. This is the origin of administrators; they are merely the officers of the ordinary, appointed by him in pursuance of the statute, which selects the nearest and most lawful friend of the deceased; these words being interpreted to denote the nearest relation by blood who is not under any legal disability. The subsequent statute of 21st Henry VIII., c. 5, enlarges a little more the power of the ecclesiastical judge, and permits him to grant administration *either* to the *widow*, or the next of kin, or to both of them; and, where several persons are equally near of kin, empowers him to select one of them at his discretion.

If none of the kindred are willing to take out administration, a creditor is permitted to do so; and in the absence of *any* person entitled to demand letters of administration, the ordinary may appoint whomsoever he may think proper, to collect the goods of the deceased, for the benefit of such as may by law be entitled to them.

Administrators may be nominated even in a case where a will has been made, if by the will no executors are appointed, or if the persons named refuse, or if they are not legally qualified to act; and in any of these cases the administrator only differs from an executor in the name of his office and mode of his appointment. In practice, when the executor *refuses* to act, it is usual to grant administration to the residuary legatee, *i. e.* to the person to whom, by the will, the remainder of the property, after payment of debts and legacies, is given.

In the case of a complete intestacy, it was formerly much doubted whether an administrator, when appointed by virtue of 31st Edward III., could be compelled to make any distribution of the effects of the intestate which remained in his hands after payment of debts; for though the administration had been transferred from the ordinary to the next of kin of the deceased, the latter stood in much the same position as the former had occupied, and was consequently not legally bound to administer. The spiritual courts endeavoured to enforce distribution by taking bonds from the administrator for that purpose, but these bonds were declared void by the common law courts. These controversies are now at an end, for the statute, commonly called the ‘Statute of Distributions,’ 22 and 23 Charles II., cap. 10, explained by 29 Car. II., cap. 30, enacts that the surplus effects, after payment of debts, shall, after the expiration of one year from the death of the intestate, be distributed in the following manner;—one-third shall go to the widow, and the remainder in equal proportions to the children of the intestate, or, if dead, to their legal representatives, *i. e.* their lineal descendants: or, if there be no children, or children's legal representatives, then one moiety shall go to the widow, and the other moiety to the next of kindred in equal degrees of relationship, or to their representatives: if no widow, the whole shall go to the children or their representatives in equal portions: if neither widow nor children, the whole shall be distributed amongst the next of kin or their representatives.

By the same statute, it is directed that no child of the intestate (except it be his heir at law) on whom he settled in his lifetime any estate in lands or pecuniary portion, equal to the distributive share of the other children, shall have any part of the surplus to be administered; but if the estates thus given him by way of advancement are not equivalent to the other shares, the child so advanced shall have enough to put him on an equality with his brothers and sisters. This is a very reasonable provision; for in the absence of all expression of the father's intention by will, it may be presumed that he had no intention of giving more to one child than to another, unless it be his heir; and as he had advanced to one child his portion, it would not be fair for that child, at the death of his father without leaving a will, to obtain a share of the property equal to that obtained by the other children who had received no advances in their father's lifetime.

The statute of distributions expressly excepts and reserves the customs of the city of London, of the province of York, and of all other places having peculiar customs of distributing intestates' effects. These customs resemble, in some degree, the provisions of the statute, though they differ from them in some respects.

For further information upon the subject of administrator and administration, which will comprise all necessary practical directions, see EXECUTORS.

ADMIRAL, the title of the highest class of naval officers. Various fanciful etymologies of the word have been given; but there can be no doubt that it is merely a corruption of the Arabic *Amir* or *Emir*, a lord or chieftain. The *al* is nothing more than the Arabic definite article *al*, *the*, without the noun to which it belongs. Eutychius, Patriarch of Alexandria, writing in the tenth century, calls the Caliph Omar *Amirol Mumenim*, which he translates into Latin *Imperator Fidelium* (the Commander of the Faithful). To form the word Admiral, the two first terms of some title similar to this have been adopted, and the third has been dropt. From this it appears that the word ought properly to be written, or rather ought at first to have been written, Amiral, or Ammiral, as we find it in Milton's expression:—

> 'The mast
> Of some great Ammiral.'

Milton, holding to this principle of orthography, wrote in Latin *Ammiralatûs Curia* (the Court of Admiralty). The French say *Amiral*, and the Italians *Ammiraglio*. The *d* seems to have got into the English word from a notion that Admiral was an abridgment of *Admirable*. The Latin writers of the middle ages sometimes, apparently from this conceit, style the commander of a fleet *Admirabilis*, and also *Admiratus*. The Spaniards say *Admirante* or *Almirante*.

Under the Greek empire, the term *Emir* or *Amir* (in Greek characters Αμηρ) was used most commonly to designate the governor of a province or district, which was itself called Αμηραδιας. Gibbon states that the emir of the fleet was the third in rank of the officers of state presiding over the navy; the first being entitled the *Great Duke*, and the second the *Great Drungaire*. [*Decline and Fall*, chap. liii.] The holy wars of the twelfth and thirteenth centuries seem to have first introduced the term Admiral into Europe. The Admiral of Sicily is reckoned among the great officers of state in that kingdom in the twelfth century; and the Genoese had also their admiral very soon after this time. In France and England the title appears to have been unknown till the latter part of the thirteenth century; the year 1284 being commonly assigned as the date of the appointment of the first French admiral, and the *Amiral de la Mer du Roy d'Angleterre* being first mentioned in records of the year 1297. The person to whom the title is given in this instance is named William de Leybourne. Yet at this time England, although she had an admiral, had, properly speaking, no fleet; the custom being for the king, when he engaged in a naval expedition, to press into his service the merchant-vessels from all ports of the kingdom, just as it is still the prerogative of the crown to seize the men serving on board such vessels. This circumstance is especially deserving of notice, as illustrating what an admiral originally was. The King of England's admiral of the sea was not necessarily the actual commander of the fleet; he was rather the great officer of state, who presided generally over maritime affairs. Sometimes he was not a professional person at all; at other times he was one of the king's sons, or other near kinsman yet in his nonage, on whom the office was bestowed, as being one of great dignity and emolument; its duties were performed by persons who acted in his name. But these duties were usually, not to command ships in battle, but merely to superintend and direct the naval strength of the kingdom, and to administer justice in all causes arising on the seas. The former of these duties is now executed by the department of government called the *Admiralty*, and the latter by the legal tribunal called the *High Court of Admiralty*.

Anciently, two or more admirals used often to be appointed to exercise their powers along different parts of the coast. Thus, in 1326, mention is made of the Admiral of the King's Fleet, from the mouth of the Thames northward, and of another officer with the same title, commanding from the mouth of the Thames westward. Besides these, there were also Admirals of the Cinque Ports. It is the opinion of some writers that the first admiral of all England was appointed in the year 1387. Even the officer bearing this title, however, was not then the person possessing the highest maritime jurisdiction. Above him there was the King's Lieutenant on the Sea (*Locum tenens super Mare.*) Also before the term Admiral was used at all, there was an officer designated the *Custos Maris*, or Guardian of the Sea.

From the year 1405 (the 6th of Henry IV.) there is an uninterrupted series of Lord High Admirals of England, the office being always held by an individual, till the 20th November, 1632, when it was for the first time put in commission. All the great officers of state were the commissioners. During the Commonwealth, the affairs of the navy were managed by a Committee of Parliament, till Cromwell took the direction of them himself. On the Restoration, the king's brother, the Duke of York, was appointed Lord High Admiral; and he retained the place till the 22d of May, 1684, when Charles took it into his own hands. On the duke's accession to the throne, in the beginning of the following year, he declared himself Lord High Admiral. On the Revolution, the office was again put in commission; and it continued to be held in this form till 1707, when Prince George of Denmark was appointed Lord High Admiral, with a council of four persons to assist him. On his death in November, 1708, the Earl of Pembroke was appointed his successor, with a similar council. The earl resigned the office in 1709, since which time, till now, it has always been in commission, with the exception of the period of about sixteen months, (from May, 1827, till September, 1828,) during which it was held by the present king, then Duke of Clarence. The commissioners, styled the Lords Commissioners of the Admiralty, were formerly seven, and are now six in number; and the First Lord is always a member of the cabinet. It is the First Lord, indeed, who principally exercises the powers of the office.

Till the reign of Queen Anne, the salary of the Lord High Admiral was only 300 marks, the emoluments of the place, which were very large, arising chiefly from perquisites, or droits, as they were called, of various descriptions. Prince George of Denmark resigned all these droits into the hands of the crown, receiving in their stead a salary of 7000*l.* a year. The salary of the First Lord of the Admiralty is at present 4,500*l.* per ann., and that of each of the others 1000*l.*

The title of admiral is also given in modern times to naval officers of the highest rank; of which we have in England three classes, namely, Admirals of the Red, of the White, and of the Blue. Admirals of the Red bear their flag at the main-top-gallant-mast-head; those of the White, at the fore-top-gallant-mast-head; and those of the Blue, at the mizen-top-gallant-mast-head. After the union with Scotland in 1707, the use of the red flag was discontinued, the union jack being substituted for it; but it was resumed at the naval promotion which took place in 1805, after the battle of Trafalgar. There are also vice-admirals and rear-admirals of each flag, the former ranking with lieutenant-generals, and the latter with major-generals in the army. A full admiral ranks with a general, and an admiral who is actually the commander-in-chief of a fleet with a field-marshal. The title of Admiral of the Fleet is merely an honorary distinction. There are also a vice-admiral and a rear-admiral of the United Kingdom, which places are now sinecures, and are usually bestowed upon naval officers of high standing and eminent services. According to the official Navy List for January, 1833, there were, in addition to the admiral of the fleet, who receives sea-pay of 6*l.* per day, forty-eight admirals, with the pay of 5*l.* per day; fifty-eight vice-admirals, with the pay of 4*l.* per day; and sixty-four rear-admirals, with the pay of 3*l.* per day. In addition to this pay, every commander-in-chief receives a further sum of 3*l.* per day while his flag shall be flying within the limits of his station.

ADMIRALTY COURTS, in Law, are courts having jurisdiction over maritime causes, whether of a civil or criminal nature. In England, the Court of Admiralty is held before the Lord High Admiral or his deputy, who is called the judge of the court: when there was a Lord High Admiral, the judge of the Admiralty usually held his place by patent from him; but when the office of admiral is executed by commissioners, he holds his place by direct commission from the crown under the great seal.

The Court of Admiralty is twofold: the Instance Court and the Prize Court; the commissions to hold these courts are perfectly distinct, but are usually given to the same person. Neither of them is a COURT of RECORD.

The civil jurisdiction of the *Instance Court* extends generally to marine contracts; that is, to such contracts as are made upon the sea, and are founded in maritime service or consideration,—as where the vessel is pledged during the voyage for necessary repairs; and to some few others, which, though entered into on land, are executed entirely upon the sea,—such as agreements for mariners' wages. But if part of a cause of action arises on the sea and part upon the land, the courts of common law exclude the Admiralty Court from its jurisdiction; and even in contracts made abroad they exercise in most cases a concurrent jurisdiction. The Admiralty Court has no cognizance of contracts under seal, except where, from the nature of the subject matter, it has exclusive jurisdiction; as in the case of an hypothecation bond, under which a ship is given in pledge for necessaries furnished to the master and mariners: this security, as it only binds the vessel on which the money is advanced, and imposes no personal contract on the borrower, does not fall within the cognizance of the common law. The Instance Court likewise regulates many other points of maritime right, such as disputes between part-owners of vessels, and questions relating to salvage, that is, the allowance made to those who have saved or recovered ships or goods from dangers of the sea. It has also power to inquire into certain wrongs or injuries committed on the high seas, such as collision, or the running foul of one ship against another, and in such cases to assess the damages to be paid to the party injured.

This court is usually held at Doctors'-Commons, like the ecclesiastical courts, to which, in its general constitution, it bears a great resemblance. The law by which its proceedings are governed is composed of such parts of the civil law as treat of maritime affairs, together with the laws of Oleron and other maritime laws, with such corrections, alterations, or amendments as have been introduced by acts of parliament or common usage. [*Blackstone's Commentaries*, vol. iii. pp. 68, 106.]

In criminal matters the Court of Admiralty has, partly by common law, partly by a variety of statutes, cognizance of piracy and all other indictable offences committed either upon the sea or on the coasts, when beyond the limits of any English county; and this (at least since the time of Edward III.) to the exclusion of the jurisdiction of courts of common law. With respect to certain felonies, committed in the main stream of great rivers below the bridges, the common law and the Admiralty have a concurrent jurisdiction.

The mode of proceeding in the Admiralty courts in criminal trials, like that in all other suits there, was anciently according to the course of the civil and marine laws; until, in the reign of Henry VIII., a statute was passed which enacted that these offences should be tried by commissioners of oyer and terminer under the king's great seal, and that the proceedings should be according to the law of the land. In pursuance of this and some later statutes, sessions of oyer and terminer and gaol delivery, called the Admiralty Sessions, are held twice a year, namely in March and October, at the Old Bailey. The acting commissioners are the judge of the Admiralty, (who, in point of form, is the presiding judge,) together with two common-law judges, and one or two civilians. [Blackstone's *Commentaries*, vol. iv. p. 268. Hale's *Pleas of the Crown*, vol. ii. p. 16.] By several recent statutes it is declared that offences committed within the jurisdiction of the Court of Admiralty shall be liable to the same punishment as if committed on land.

The Prize-Court is the only tribunal for deciding what is, and what is not, lawful prize, and for adjudicating upon all matters civil and criminal relating to prize. By '*prize*,' is to be understood every acquisition made *jure belli* (by right of war) which is either itself of a maritime character, or is made, whether at sea or by land, by a naval force. All acquisitions by right of war are by the law of war vested in the sovereign, but are usually, by the municipal regulations of each particular state, (as in England by several acts of parliament,) distributed in certain proportions among the persons who took or assisted in taking them. But the property in the thing captured is held by English jurists, agreeably to the general practice of the law of nations, not to be absolutely taken from the original owners, until, by the sentence of a properly authorized court, it has been condemned as lawful prize. We have, as it should appear, no court authorized to adjudicate on property captured by land-forces, or *booty*, as it is commonly termed by writers on the law of nations; but, when occasion requires, (as, for instance, of late years, when property to an immense amount was captured by the British army in the conquest of the Deccan,) commissioners are specially appointed for the purpose. But property captured by the naval force forms the peculiar province of the Prize-Court of the Admiralty. "The end of a Prize-Court," says Lord Mansfield, "is to suspend the property till condemnation; to punish every sort of misbehaviour in the captors; to restore instantly, if upon the most summary examination there does not appear sufficient ground; to condemn finally, if the goods really are prize, against every body, giving every body a fair opportunity of being heard." [See Douglas's *Reports*, p. 572, &c.]

Every sovereign power has a right to erect Admiralty Courts for the trial of prizes taken by virtue of the commissions which it has granted; but has no power to reverse the sentences given by the tribunals of another state: the only regular method of rectifying their errors is by appeal to the superior court.

The Cinque Ports have an exclusive Admiralty jurisdiction of their own: in Ireland, there has been an Instance Court from time immemorial; and there is an Admiralty Court in Scotland with very extensive civil jurisdiction. In several of our colonies there are courts of Vice-Admiralty, which not only have authority both as Instance Courts and Prize Courts, but have also, in certain revenue cases, concurrent jurisdiction with the colonial courts of record. [Stokes, *On the Colonies*, p. 357.] From the Vice-Admiralty Courts of the colonies an appeal lies, in instance causes, to the Court of Admiralty in England; and from the Court of Admiralty in England an appeal lies, in instance causes, (whether originating in that court or coming before it by appeal) to the king in council. See statute 2 and 3 Will. IV. c. 92. From prize causes, whether in the Vice-Admiralty Courts, or in the Court of Admiralty in England, the appeal lies directly to certain commissioners of appeal in prize causes, who are appointed by the king under the great seal, and are usually members of his privy council, and whose appointment is generally regulated or recognized by treaties with foreign nations.

For the law on the whole of this subject, see Dr. Browne's *View of the Civil Law*, and the *Law of the Admiralty*, and Comyn's *Digest*, tit. *Admiralty*.

ADMIRALTY ISLANDS. A group of islands, consisting of one larger and about 40 smaller, which are generally classed in the division of Australia. They lie south of the equator between the second and third degree of latitude, and between 146° 18′, and 147° 46′ E. long.; and were discovered by the Dutch in 1616. Captain Carteret visited them in 1767, and the Spanish navigator Morello in 1781. d'Entrecasteaux, who was despatched to see if any trace of La Perouse's crew could be found, visited these islands in 1793. The soil and climate are said to be good, but the landing is rendered difficult by reason of reefs and breakers. A number of small islands and reefs form a cordon round the large one, which is difficult of approach, and no landing was made on it by d'Entrecasteaux. Only those islands seemed to be inhabited which had cocoa-nut trees on them. As they are very little elevated above the level of the sea, water must necessarily be scarce. The largest island is about 45 miles long, and like most of them, principally covered with cocoa-nut trees; the inhabitants are of a dark colour with frizzled hair, and they go naked. They are described as good looking and well made. To the French navigator they seemed a tolerably well-disposed people, though Carteret's account of them is unfavourable. They point their lances with a species of hard stone. When the French visited the island, the people showed the greatest eagerness to possess iron, which it is conjectured they first obtained from the Spaniards. [See *d'Entrecasteaux's Voyage*, Paris, 1808, 2 vols. 4to.]

ADMIRALTY ISLAND, on the N.W. coast of North America, in the Archipelago of George III., and within that part of the continent which, since the treaty of 1825, belongs to what we call Russian America. Admiralty Island is about 80 miles long, and, in some parts, 20 wide: it lies between 57° 2′, and 58° 24′ N. lat., and 134° 52′, and 135° 30′ W. long. The island was completely circumnavigated by Vancouver, who considers it to be about 60 leagues in circuit. With the exception particularly of the S.E. coast, the shores are bold, and afford many convenient bays with fine streams of fresh water running into them. The island is moderately elevated and rocky, but covered with forests, especially pine. The natives of the island carry on some little trade with Europeans. [See *Vancouver's Voyage*, vol. iii. p. 277.]

ADO'NIS, a river of ancient Syria, which rises in the mountains of Lebanon. It has the same name with a personage of considerable importance in Pagan mythology, of whose story the following is a brief sketch:—'Adonis, son of Myrrha, daughter of Cinyras, King of Cyprus, was born in Arabia, whither his mother had fled in consequence of certain transactions which it is not necessary to relate. Before the birth of her son she was transformed into the tree which produces the fragrant gum called by her name; this, however, did not hinder his being brought into the world in due season: he grew up a model of manly beauty, and was passionately beloved by Aphrodite (Venus), who quitted Olympus to dwell with him. Hunting was his favorite pursuit, until, having gone to the chase against the entreaties of his mistress, he was mortally wounded in the thigh by a wild boar. After death he was said to stand as high in the favour of Persephone (Proserpine), as before in that of Aphrodite; but the latter being inconsolable, her rival generously consented that Adonis should spend half the year with his celestial, half with his infernal mistress. The fable has been variously interpreted. One explanation makes the alternate abode of Adonis above and under the earth, typical of the burial of seed, which in due season rises above ground for the propagation of its species; another, of the annual passage of the sun from the northern to the southern hemisphere.—In the time of Pausanias, in the second century of our æra, there existed an ancient temple of Adonis and Aphrodite, at Amathus, in Cyprus.

The story of Adonis appears to have been introduced into Greece from Syria. According to Pausanias, Sappho sung of Adonis; and his name, with allusion to his rites, occurs in a fragment of Alcæus. But it is by the Greek poets of later date, and their Latin imitators, Theocritus, Bion, Ovid, that his story has been probably expanded, and invested with the elegance which is the peculiar character of Grecian mythology. The Adonia are mentioned by Aristophanes among the Athenian festivals, and this is (we believe) the earliest mention of them, except some notice in the poems attributed to Orpheus, (the epoch of which is, however, too doubtful to be received as authority,) and the songs attributed to Sappho and Alcæus. The rites began with mourning for the death of Adonis—(thus Ezekiel, viii. 13, 'He brought me to the door of the Lord's house . . . . and behold, there sat women weeping for Thammuz'); then changed into rejoicing for his return to life and to Aphrodite; and concluded with a procession, in which the images of Adonis and Aphrodite were carried, with rich offerings, in separate couches; after which the former appears to have been thrown into the sea. See Theocr. Idyll. xv. In the time of Pausanias, the women of Argos, in the Peloponnesus, lamented Adonis.

In Syria we know the worship of Adonis (if, according to the received notion, he be the same personage as Thammuz) to be probably of much older date. We know, from the passage in Ezekiel already quoted, that the adoration of the latter was one of the abominations of Judah six centuries before Christ. Whatever resemblance there may have been between the early Syrian and Grecian rites, the former were far more deeply polluted by the atrocities of a brutish superstition, to which the natives of Syria were unusually prone. Byblos, a town near the river Adonis, was one of the chief seats of this worship, which was intimately connected with a peculiarity incident to the river. Its waters, at a certain period of the year, assume a deep red, and were said to be discoloured by the blood of Adonis.

> ....'Thammuz came next behind,
> Whose annual wound in Lebanon allured
> The Syrian damsels to lament his fate
> In amorous ditties all a summer's day,
> While smooth Adonis, from his native rock,
> Ran purple to the sea, supposed with blood
> Of Thammuz, yearly wounded.'
>
> *Paradise Lost*, i. 446.

The phenomenon has been observed by modern travellers, and is attributed to the rains, which bring a quantity of red earth into the stream. [See Maundrell's *Travels.*] This, which probably is the true solution, was suggested even in the time of Lucian.—[*De Dea Syria*, § 8.]

ADO'NIS, in Botany, is a genus of plants belonging to the natural order ranunculaceæ, and containing many species of very great beauty. The name is merely poetical. Adonis is distinguished from ranunculus by the want of a little scale at the base of the petals, and from other genera of the order by the numerous hard, dry, sharp-pointed grains of which its fruit consists.

Botanists divide the genus into two sections, the first of which comprehends all the annual kinds, the second all the perennials. Ten species are spoken of as belonging to the first section, inhabiting corn-fields and similar dry exposed places, chiefly in the south of Europe and north of Africa. Some of them have deep crimson flowers, as *A. autumnalis*, the common pheasant's-eye of our gardens; in others the blossoms are yellow; it is not improbable that they are all varieties of the same species.

Of the perennial kinds, *A. vernalis*, which is common in gardens in England, is found in a wild state abundantly on all the mountains of middle Europe. Its flowers have from ten to twelve petals of a yellow colour, and of a brilliancy which is rendered the more dazzling by the deep green tuft of finely divided leaves among which they expand. It is only a few inches high, and is one of the early harbingers of spring. Three others are described, all mountain plants, resembling *A. vernalis* in general appearance, but perhaps still more beautiful. They seem to have been occasionally brought to this country, but to have been soon lost again.

Nothing has been remarked as to the sensible properties of these plants; they doubtless partake of the acridity so prevalent in their tribe.

ADOPTION, (from *adoptare*, Latin,) means taking by choice. By the Roman law if a person had no children of his own he might appoint any other person's, whether related to him or not, to be his children *by adoption*. In order to understand the ordinary mode of adoption and its legal effects, it will be necessary to remember that at Rome the relation of father and son was but little different from that of master and slave, either in the rights and duties attached to it, or in the manner in which it was dissolved. Hence, if a person wished to adopt the son of another, the natural father sold the boy to him by a regular sale before a magistrate, and, in order that he might be so completely emancipated from his father's authority, as never to be liable to fall under it again, it was requisite that this sale should be formally repeated three several times. (See EMANCIPATION.) The father thus conveyed away all his paternal rights, and the child, from that moment, became, to all intents and purposes, a member of the family of his adopter. If the person to be adopted was his own master, the mode of proceeding was by a bill (analogous to our private acts of parliament), proposed to the people in the comitia curiata. This was called ARROGATION, from *rogare*, to propose a bill. In either case the adopted child became subject to the authority of his new father; passed into his family, name, and sacred rites, and succeeded to his property. Clodius, the enemy of Cicero, passed, by this ceremony of a bill, from the patrician to the plebeian rank, in order to qualify him to be tribune. [Cic. *Att.* ii. 7. Suet. *Aug.* 20.]

The history of Rome abounds with instances of adoption. Thus one of the sons of Paulus Æmilius, the conqueror of Macedonia, was adopted by the son of Scipio Africanus the Elder, and thus acquired the name of *Publius Cornelius Scipio;* he was also called *Æmilianus*, to point out the family of his birth; and when he had destroyed Carthage in the third Punic War, he received, like his adoptive grandfather, the appellation of *Africanus*, and is usually spoken of in history as Scipio Africanus the Younger.

Under the emperors the mode of adoption became the subject of legal reform; and that which for so many ages could be effected only by a circuitous course of arbitrary forms, founded upon legal fictions, was allowed to be done by a short and simple process before a magistrate.

There was also a custom in ancient Rome of adopting children by will: thus it was that Julius Cæsar adopted his great nephew Octavius, who was thenceforth called Caius Julius Cæsar Octavianus; but is most generally known under the more pompous appellation of AUGUSTUS, which he afterwards assumed.—[Heineccius, *Antiquitates Romanæ*, lib. i., tit. xi.] In like manner, several of the Roman emperors adopted their successors; for instance, Augustus adopted his step-sons, Tiberius, Nero, and Claudius Drusus, the former of whom afterwards succeeded to the empire. [Tacit. *Ann.* i. 3. Suet. *Aug.* 101.] So also Tiberius, by the order, and during the life-time of Augustus, adopted his nephew Germanicus, who died in the lifetime of Tiberius; and on the death of Tiberius, Caligula, the son of Germanicus, became emperor. At a subsequent period, the emperor Claudius went so far as to adopt his step-son Domitius, afterwards the emperor Nero, to the exclusion of his own son Britannicus. Tacitus remarks, that Nero was the first stranger in blood ever adopted into the Claudian family.—[Tacit. *Annal.* xii. 25.] At various periods of the Roman history, great inconvenience was experienced in consequence of the general disinclination to marriage among the citizens. Before the times of the emperors, it is clear that, in order to remove this inconvenience, rewards were held out for the encouragement of marriage, and penalties imposed upon celibacy. Immunities and exemptions from state burthens were also given to those who possessed many children; and in order to obtain these, the adoption of children became a great abuse. Aulus Gellius complains of the mischievous custom prevalent in his time, that 'an adoptive son should entitle his adoptive father to privileges in the state.'—[Aul. Gel. *Noct. Att.* v. 19.] Under Julius Cæsar, after the wars, laws for the encouragement of population were proposed, but not carried into effect: but in the time of Augustus, the Julian law was proposed, A.U.C. 736, which contained heavy penalties upon celibacy, and proportionate rewards for the possession of children. This law was so extremely unpopular, that, Suetonius says, it could not be executed, on account of the tumultuous opposition raised to it.—[Sueton. *Aug*. 34.] Afterwards, however, a law passed, called from the Consuls who introduced it, 'Lex Papia Poppæa;' by which many privileges were given to those who possessed children; and amongst others, it was declared that, of candidates for prætorships and other offices, those should have the preference who had the greatest number of children. This occasioned an intolerable abuse in the adoption of children. Tacitus says, that in the time of Nero, a 'pestilent abuse was practised by childless men; who, whenever the election of magistrates or the allotment of provinces was at hand, provided themselves with sons by fraudulent adoptions; and then when, in common with real fathers, they had obtained prætorships and provincial governments, they instantly released themselves from their adopted sons. Hence the genuine fathers betook themselves with mighty indignation to the senate,' and petitioned for relief. This produced a decree that in the pursuit of any public employment whatever, no feigned adoptions should be of any avail, nor in taking estate by will.—[See Tacit. *Annal.* xv. 19.]

The eleventh title of the first book of Justinian's *Institutes* is concerning Adoption. By this law it is declared that there are two kinds of adoption, one called *arrogatio*, when by a rescript of the emperor, (*principali rescripto*,) a person adopts another who is independent of parents; the other, when by the authority of the magistrate (*imperio magistratûs*), he who is under the control of his parent is made over by that parent to another person, and adopted by him either as his son, his grandson, or a relation in any inferior degree. Females also might be adopted in the same manner. But when a man gave his child to be adopted by a stranger, none of the parental authority passed from the natural to the adoptive father; the only effect was, that the child succeeded to the inheritance of the latter if he died intestate. It was only when the adopter was the child's paternal or maternal grandfather, or otherwise so related to him as that the right of nature concurred with that of adoption, that the new connection became, in all respects, the same with the original one. It was also ordained that the adopter should in all cases be at least eighteen years older than the person he adopted. Women, according to the Justinian code, were not legally entitled to adopt; but after having lost children of their own by death, they might by the indulgence of the emperor be permitted to receive those of others in their place. A slave, on being named a son by his master before a magistrate, became free, but acquired no filial right.

The German system of adoption is derived from the Roman law, though it cannot be said, according to the proper meaning of the word, to have been in force before the fifteenth or sixteenth century. Any adoption, in order to be strictly and properly a *legal* process, must take place before a court, or be confirmed by the proper authorities. The adopted son retains his family name, and prefixes or adds to it that of his adoptive father; but in case a nobleman adopts a commoner, the son does not succeed to the rank, unless it is confirmed by the sovereign. The more modern German institutes still keep to the *principles* of the Roman system of adoption, though the whole is modified so as to be more in harmony with German usages. The Prussian law does away with all distinction between *adoption* and *arrogation;* and allows the adopted son who is of age to manage his *own* property. The Austrian law does the same. Both also agree in requiring the age of the adoptive father to be fifty at least. The Prussian law, with respect to the adopted son, merely requires him to be younger than the father; while the Austrian code requires him to be eighteen years younger than the adoptive father. [Ersch and Gruber's *Encyclopädie*, Art. *Adoption*.]

The French law of adoption is to be found in the eighth title of the first book of the *Code Civil*. The following are its principal provisions. Adoption is only permitted to persons above the age of fifty, having neither children nor other legitimate descendants, and being at least fifteen years older than the individual adopted. It can only be exercised in favour of one who has been an object of the adopter's constant care for at least six years during minority, or of one who has saved the life of the adopter in battle, from fire, or from drowning. In the latter cases, the only restriction respecting the age of the parties is, that the adopter shall be older than the adopted, and shall have attained his majority, or his twenty-first year. In every case the party adopted must be of this age. The form is for the two parties to present themselves before the justice of the peace (*juge de paix*) for the place where the adopter resides, and in his presence to pass an act of mutual consent; after which the transaction, before being accounted valid, must be approved of by the tribunal of *first instance*, within whose jurisdiction the domicile of the adopter is. The adopted takes the name of the adopter in addition to his own; and no marriage can take place between the adopter and either the adopted or his descendants, or between two adopted children of the same individual, or between the adopted and any child who may be afterwards born to the adopter, or between the one party and the wife of the other. The adopted acquires no right of succession to the property of any relations of the adopter; but in regard to the property of the adopter himself, it is declared that he shall have precisely the same rights with a child born in wedlock, and that, even although there should be other children of the latter description born after his adoption.

Adoption is still practised both among the Turks and among other eastern nations. It is common for a rich Turk, who has no children of his own, to adopt as his heir the child of persons even of the poorest class. The bargain is ratified by the parties going together before the Cadi, and getting their mutual consent recorded; after which the child cannot be disinherited by his adoptive father. D'Herbelot states, that, according to the law of Mohammed, a person becomes the adopted son of another by undergoing the ceremony of passing through his shirt; whence the expression, to draw another through one's shirt, signifies to adopt him for a son. In India the same thing is said to be frequently done by the two parties merely exchanging girdles. In the Code of Gentoo Laws published by Mr. Halhed, the 9th section of the 21st chapter is entitled 'Of Adoption.' The law permits a child under five years of age to be given up for adoption by its father for a payment of gold or rice, if he have other sons, on the parties going before a magistrate and having a *jugg*, or sacrifice, performed. A woman, however, it is added, may not adopt a child without having her husband's consent; and there is even some doubt if she may with that. 'He,' concludes the law, 'who has no son, or grandson, or grandson's son, or brother's son, shall' (may?) 'adopt a son; and while he has one adopted son, he shall not adopt a second.'

ADOU'R, called by the Roman writers Atur, Aturis, and Aturus, a river in France, which rises in the department of Hautes Pyrenées (the Upper Pyrenees). Its course is first in a northerly direction, past the town of Bagnères de Bigorre (just above which there is a fall of one hundred feet); then towards the west, and finally towards the south-west, passing the towns of Tarbes, Aire, St. Sever (where it becomes navigable), Dax, and Bayonne, and describing in its whole course a semicircle, whose diameter, of about 100 miles, lies nearly N.N.W. and S.S.E. The whole length of the river is estimated by Maltebrun at 70 French leagues, or about 170 English miles. Its basin is bounded by the Pyrenees on the south, and on the east by a range of hills, extending from these mountains towards the sandy plains of the department of Gironde. Many streams from the Pyrenees, as the Gabas, Luy de France, Luy de Bearn, Gave de Pau, which receives the Gave d'Oléron and the Bidouze, fall into the Adour on the left bank; the Midouze, and others, on the right. The current is usually rapid, and the melting of the snows on the Pyrenees causes desolating inundations. The Adour falls into the Bay of Biscay, about three miles below the strong and flourishing town of Bayonne, having a bar at the mouth, upon which, at ebb tide, there is sometimes less than three feet water.

ADO'WA, one of the chief places in Abyssinia in the kingdom of Tigré, and in the district of Adowa, which is a part of Tigré proper (N. lat. 14° 12′ 30″, E. long. 39° 5′). It is partly on the side, and partly at the foot of a hill, an uncommon occurrence in Tigré, where most of the towns are on eminences. The houses are all of a conical form, and arranged pretty regularly in streets. The town is well supplied with water from those rivulets which fall into the Mareb, and grapes grow well in the gardens. Adowa from its position is the great mart between the coast and the interior provinces, and carries on a considerable trade, which is mostly in the hands of Mohammedan merchants. The population is probably not under eight thousand. Mr. Bruce informs us that the Jews have the sole privilege of thatching houses at Adowa, which, when rightly interpreted, may mean that they are the only persons who can do it well.

The chief manufactures of Adowa are coarse and fine cotton cloths, made both of native cotton from the low lands on the Tacazzé, and from cotton imported through Massowa on the coast of the Red Sea. Mr. Salt mentions the following as the chief imports which pass through Adowa for the Gondar market: a small quantity of lead, block tin, copper, and gold foil; small and cheap Persian carpets, raw silk from China, some velvets, French broad cloths, and coloured skins from Egypt; Venetian glass ware and beads, and such other small commodities as in various ways happen to be taken to Jidda, the port of Mecca. The commodities which mostly pass through the hands of the Adowa merchants for export, are ivory, gold, and slaves. A large part of the ivory comes from the province of Walkayt, which lies on the Tacazzé, and from the low lands north of Shiré, on the Mareb river, which abound in elephants. The gold is collected in the interior, but as to the amount that passes through Adowa, Mr. Salt is unable to state it with accuracy, owing to this branch of commerce being carried on with great secrecy. He computes the slaves exported at about a thousand annually. (Salt's *Abyssinia*, p. 424, &c.) Mr. Bruce says that the word 'Adowa' signifies 'pass or passage,' which therefore, we presume, he means to assert is the correct interpretation of 'Adowa' in the Tigré language. [See ABYSSINIA.]

ADO'XA *Moschatellina*, is a little inconspicuous plant found in woods and groves in all parts of Europe. It is common in Charlton and Hampstead woods, near London, and in many other spots in England.

From a granular root, which when dry is white as snow, arise, early every spring, a few leaves about four or five inches high, divided into three principal divisions, each of which is also three-leaved, with every lobe deeply cut into roundish segments. The stem that supports the flowers has two opposite leaves, like those of the root, only they have a short stalk, and consist of but three leaflets. The flowers have a musky smell, are pale green, and are collected in little round heads. Each one consists of a superior calyx of five lobes; there are no petals; the stamens are ten; the styles five; and the ovarium contains five cells. This last changes to a succulent berry, having five compressed seeds.

In English this is called moschatel; it is a pretty, interesting plant, much sought after by the curious for the sake of its delicate, modest appearance. No known properties belong to it: but it is remarkable as the only European plant which can be compared to the celebrated ginseng of the Chinese, that potent root, which is fabled to possess the power of even restoring youth to old age.

A'DRIA, formerly HADRIA or ATRIA, an ancient city, situated between the mouths of the Po and the Adige, first belonging to the Etrusci, afterwards a confederate city of the Romans, and a municipium. It was a sea-port town, carried on an extensive trade on the Adriatic, and was a station for the Roman fleet under the emperors. After the fall of the empire, the inundations of the Po and the Adige, in consequence of the neglect of the dykes and the mischief caused by the barbarians, rendered the country around marshy and uninhabitable. The alluvial soil in the course of ages gradually encroached upon the sea along this coast, and thus Adria became first joined to the main land, from which it was previously detached; and the sea receding from it gradually more and more, the town is now fourteen miles inland. The same causes continuing to operate, the ground was raised by the alluvions many feet above the former level, so as gradually to cover the old forests. Adria, however, although in a state of decay, was never totally destroyed. In 430 it was subject to the Greek empire, having its own magistrates. It made part of the Exarchate of Ravenna, and afterwards came with it under the dominion of the Roman See. In the ninth century we find it governed by its own bishops, under the joint protection of the popes and the emperors. It afterwards formed part of the Marquisate of Este and Ferrara. In the war between Hercules, Duke of Ferrara, and the Venetians, in 1482, Adria was besieged and taken by the latter, and then pillaged and burnt. The citizens who had escaped, having made their submission to the Venetian senate, were restored to their lands and houses, which they began to repair or rebuild. After the war of the league of Cambrai, Adria was, by the peace of Bologna in 1529, definitively given up to Venice. The new town of Adria by degrees arose out of the ruins of the old city, a great part of which had been long before buried under the successive alluvions. Its remains lie to the south of the present town towards Ravegnano, where the old massive walls, and the ruins of an amphitheatre, of baths, aqueducts and mosaic pavements, and other Etruscan and Roman antiquities, are found many feet below the surface of the ground. There is an interesting collection of antiquities that have been dug up, in the house of Mr. Bocchi. The present town of Adria is crossed by the Castagnaro, a branch of the Adige; it has about 9600 inhabitants, and is a bishop's see, although, of late, the bishops reside mostly at Rovigo, which is fifteen miles to the westward of it. The territory of Adria borders on the Roman Legation of Ferrara, the town itself being only three miles north of the Po. Pliny the Elder speaks of the wines of Adria with praise; the country still produces some tolerable wine, and the town trades in cattle, grain, silk, flax, firewood, leather, and earthenware. Under the republic of Venice, Adria was annexed to the Dogado or province of Venice proper, and was governed by a patrician with the title of Podestà, having its own municipal councils and statutes, which were printed in 1707. It now forms part of the Lombardo-Venetian kingdom under the crown of Austria. Luigi Groto, called also the 'blind man of Adria,' a learned man of the sixteenth century, was a native of this town. Adria lies 30 miles S.S.W. of Venice, N. lat. 45° 3', E. long. 11° 1'.

ADRIAN. [See HADRIAN.]

ADRIAN I., Pope, born at Rome, succeeded Stephen III. in 772. Like his predecessor, he had to struggle against the power of the Longobards, who had invaded the Exarchate and other provinces bestowed by Pepin, king of the Franks, on the Roman see. Devastating with fire and sword Sinigaglia, Urbino, and other cities, they advanced as far as Otricoli, on the Tiber, and threatened Rome with the same fate. Desiderius, king of the Longobards, had taken under his protection the two sons of Carloman, the deceased brother of Charlemagne, and he wished Adrian to consecrate them as kings of the Franks, in opposition to their uncle. Adrian refused to do this; and hence arose the bitter enmity of Desiderius. Adrian applied to Charlemagne for assistance. The king of the Franks crossed the Alps by the way of Susa, defeated Desiderius, and overthrew the kingdom of the Longobards in Italy, in 774. Charlemagne then went to Rome, where he arrived on Easter eve, and was received by Adrian with great honours. They repaired together to the Basilica of St. Peter, where Adrian acknowledged Charles as king of Italy, and "Patrician of Rome," and the latter renewed the grant of the provinces bestowed on the Roman see by Pepin. The temporal authority of the popes, however, was far from being permanently established for a long time after; and there are repeated letters from Adrian to Charles, complaining that Bologna, the Romagna, and even Sabina, had not been restored to the jurisdiction of St. Peter. Charlemagne paid another visit to Adrian at Rome in 787, when his son Pepin was christened by the pope. In 787, the seventh general council of the church was held at Nicæa, in Bithynia, where Adrian sent his legates, and in which the worship of images was confirmed, and the iconoclasts were excommunicated. In 791, there was a dreadful inundation at Rome, caused by the overflowing of the Tiber, and Adrian exerted himself in supplying with provisions the inhabitants, by means of boats, which plied to the various parts of the city. He also rebuilt the walls and towers of Rome, and was liberal to the poor. He died after a long pontificate of nearly twenty-four years, on Christmas-day, 795. Charlemagne was much grieved at the news of his death, and wrote his epitaph in Latin verses, in which he affectionately calls him "father." Adrian was a man of talent and dexterity; he succeeded in gaining and preserving the friendship of the greatest sovereign of his time, and he used his influence for the security and prosperity of the people of Rome, and its duchy or territory, without at the same time neglecting the temporal interests of his see. Under him Rome began to breathe again after the continual alarms caused by the Longobards, the last of the barbarian invaders of the Western Empire.—[See Anastasius in Muratori's *Rerum Italicarum Scriptores*, tom. iii.]

ADRIAN II., born at Rome, succeeded Nicholas I. in the papal chair, in 867. He had been married, and had a daughter by his wife Stephania, from whom he afterwards separated in order to live in celibacy. After his election, his wife and daughter continued to live at Rome in a separate house, when an unprincipled man, called Eleutherius, carried off the girl by violence, and on the pontiff retaking his child, the ravisher forced his way into the house and murdered both mother and daughter. For this crime he was tried and sentenced to death by the imperial commissioners, who still exercised the high judicature at Rome. During the pontificate of Adrian, the emperor Ludovicus II. was in Southern Italy, warring against the Saracens, who had invaded part of Calabria and Puglia; he defeated them and took the town of Bari, in 871. It was also during Adrian's pontificate, that Photius, patriarch of Constantinople, withdrew from the Church of Rome, from which time the schism between the Greek and Latin churches dates, which continues to this day. Adrian died in 872, and was succeeded by John VIII.

ADRIAN III., born at Rome, succeeded Marinus in 884, and died the following year on his journey to attend the imperial diet at Worms, after a pontificate of only fifteen months.

ADRIAN IV., an Englishman, whose name was Nicholas Breakspeare, succeeded Anastasius IV. in 1154. He had been a monk, and was made bishop of Albano by Eugenius III., who sent him as his legate, or apostle, as it was then called, to Denmark and Norway. On his return he was elected pope much against his inclination. Rome was then in a very disturbed state. Arnaldo of Brescia, a monk and a disciple of Abelard, had begun to preach a reform in the church as early as 1139, but being driven out of Rome by Pope Innocent II., had taken refuge at Zürich. In 1143, however, he was recalled by the Roman people, who had revolted against Innocent, and had proclaimed a Roman republic, which Arnaldo contributed to constitute. The new government consisted of a senate of fifty-six members, who were annually chosen by an electoral body composed of delegates, ten from each of the thirteen districts of the city. This constitution lasted about fifty years. Arnaldo, who was an eloquent man, strongly condemned the temporalities of the church, and wished to restrict the pope's office to mere spiritual matters. Although he preached no dogma in opposition to the canons, he was condemned by the second council of Lateran, his opinions being styled *political heresy*. Arnaldo partook largely of the newly revived classical fanaticism of those times, which mistook recollections for realities; and he seriously maintained that Rome ought to be, and would again become, the mistress of the world. Several successive popes, Celestin II., Lucius II., and Eugenius III. kept up a sort of desultory struggle against this popular reformer. Lucius in an affray was pelted with stones, and died of the injury received. His successor, Eugenius, was obliged to leave Rome and retire into Sabina. During the confusion that prevailed in the city, the populace plundered and afterwards pulled down the houses of many nobles, cardinals, and citizens, and committed other acts of violence. Adrian IV., after his election, placed Rome under interdict on account of these disorders, and caused all religious services to cease; which measure led the citizens to banish Arnaldo, who took refuge with some barons of Campania; and Adrian then came to reside in the Lateran palace. Frederic of Hohenstauffen, known in Italian history by the name of Barbarossa, had lately been elected emperor by the German Diet, and was on his way to Rome to be crowned. The pope's legates met him on the road, and among other remonstrances, requested that the heretic Arnaldo should be given up by the Viscount of Campania, in order to be tried. Frederic assented to this, and issued orders in consequence; others say that Cardinal Gerard took Arnaldo prisoner, after an obstinate resistance. He was brought to Rome, and delivered to the prefect of the city, by whose sentence he was hanged, his body burnt, and the ashes scattered to the winds, in the year 1155. Meantime Frederic approached Rome with his army, and Adrian went to meet him near Sutri, where, on the latter dismounting, Frederic refused to hold his stirrup, a ceremony on which the popes always insisted, as a mark of respect for their spiritual supremacy. The pope, on his side, refused to salute the emperor with the "kiss of peace," upon which the cardinals were terrified and ran away to Cività Castellana. The question of the ceremonial was debated for two days, when Frederic, having ascertained that such had been the practice with his predecessors, agreed to conform to it. They met, therefore, again at Nepi, and Frederic having held the stirrup, Adrian gave him the *osculum pacis*, and both proceeded towards Rome. The senate and Roman people had on their part sent orators to Frederic, offering him, with their allegiance, the imperial crown, but demanding at the same time five thousand lbs. of silver for the expenses of the coronation, and that the temporal government of the city should be left to them, to the exclusion of the pope. Frederic answered, that he came to give and not to receive laws, and with his army he took possession of the Leonine city on the north bank of the Tiber, and of St. Peter's church, where he was crowned by the pope on the following day. The Romans, however, took no part in the ceremony, but after having held a council in the Capitol, sallied out and attacked the German soldiers unawares. A general battle took place, and continued with great slaughter on both sides, till night separated the combatants. The city continuing in a disturbed state, both the pope and emperor withdrew to Tivoli, whence Frederic returned towards Lombardy. Adrian went afterwards to Benevento, where he made peace with William I., king of Sicily, whom he had excommunicated; and upon their reconciliation he agreed to give him the investiture of Sicily, Calabria, and Apulia, in 1156, on condition of the latter paying a yearly tribute to the see of Rome. The pope returned loaded with rich presents of silks, gold, and silver, and passing through Rome, went to reside at Orvieto, which was subject to the Roman see. Frederic now complained that the pope had violated his faith, by receiving ambassadors and entering into treaties with the king of Sicily and the Greek emperor, without his participation. He also resented the pretensions of the pope and his legates, who seemed to assume that the imperial crown was granted as a *beneficium*, or fee of the see of Rome. Adrian, on his part, complained of the exactions of the imperial commissioners who were sent to administer justice at Rome without his participation; he maintained that the patrimony of the church should be exempt from paying *foderum*, or feudal tribute to the emperor; and, lastly, he claimed the restitution of the lands and revenues of Countess Matilda, of the duchy of Spoleti, and even of Corsica and Sardinia. Thus arose that spirit of bitter hostility between the popes and the house of Hohenstauffen, which lasted until the utter extinction of the latter. But the seeds only were sown in Adrian s time. He died in the beginning of September, 1159, in the town of Anagni, and was succeeded by Alexander III. From the above sketch it may be seen that Adrian IV. stretched the papal prerogatives as far as any of his predecessors had done, Gregory VII. not excepted. [See Fleury. *Histoire Ecclésiastique*, and Raumer, *Geschichte der Hohenstauffen und ihrer Zeit*.]

ADRIAN V., a Genoese, succeeded Innocent in 1276, and died five weeks after his election. He was succeeded by John XX.

ADRIAN VI., born at Utrecht in the Netherlands, of an obscure family, advanced himself by his talents to the post of vice-chancellor of the University of Louvain. The Emperor Maximilian chose him as preceptor to his grandson, afterwards Charles V. Ferdinand of Spain gave him the bishopric of Tortosa. After Ferdinand's death he was co-regent of Spain with Cardinal Ximenes. He was elected pope in 1522, after the death of Leo X., chiefly through the influence of Charles V. whose authority was then spreading over Italy. Adrian was a virtuous and austere clergyman; he endeavoured to reform the numerous abuses of the court and clergy of Rome; he practised a severe economy, and lived frugally. By so doing he displeased the Romans, who had been accustomed to the luxury and prodigality of Leo; and when he died, in September, 1523, after a short pontificate, the people could not conceal their joy. They styled his physician 'the saviour of his country.' He was succeeded by Clement VII. Adrian appears to have been an honest, conscientious man, who fell upon evil times, and was unequal to the difficulties which he had to encounter. He was desirous of maintaining peace, and of stopping, if possible, the schism of the Lutherans by reforming the church, but he did not live long enough to effect any thing essential. Burmann published his life at Utrecht, in 1727.

ADRIANO′PLE, called Edreneh by the Turks, the second city in European Turkey, is in the province of Romania or Rumelia, and on the river Maritza, the ancient Hebrus, which is here joined by the Toonja and the Arda, N. lat. 41° 44′, E. long. 26° 34′, and 135 miles N. W. of Constantinople. It takes its name from the Roman Emperor Adrian (properly written Hadrian) who restored and embel lished it, as he did so many other cities of his dominions. Adrianople 'rises gently on the side of a small hill from the banks of the Hebrus and Tunsa,' [Chishull,] and is about five miles in circumference. When Chishull passed through this city (in 1701) it was the occasional residence of the sultan, whose seraglio stood on a low ground near the confluence of the Maritza and Tunja, embosomed in trees: it is now in a state of dilapidation. The streets of the town are narrow and irregular, but it is well provided with mosques, forty in number, and with baths. The number of inhabitants is 130,000, of whom 30,000 are Greeks. Mr. Alexander, a recent traveller, thinks there may be only 100,000. One of the mosques, that of Sultan Mourad I., was once a Christian church, and another has a great quantity of porphyry in its construction; but the great boast of the town is the mosque of Selim II., built chiefly of materials brought from the ruins of Famagosta, in Cyprus. It consists of one great apartment like a theatre, terminating in a cupola, and has four regular minarets, to the highest balcony of which there is an ascent by 244 steps, or, according to other accounts, 380. But one of the most important constructions of Adrianople is the bazaar of Ali Pacha, near the mosque of Sultan Selim: Chishull says, 'the *sharshées* are two long and fair porticos, walled with brick or stone on each side, and securely arched over head so as to resist fire. The shorter of these adjoins Sultan Selim, and is appropriated to the shoemakers: but the other, being about 400 paces long and 6 broad, is filled with shops of various trades.' Chishull mentions also a madhouse, kept very neat and clean, but the unfortunate inmates were fastened close to the ground by an iron chain round their necks. A large aqueduct supplies the baths, mosques, and fountains with water. Many traces of Roman building may be seen at Adrianople; and several inscriptions have been lately discovered, as well as the trunk of a colossal statue about 12 feet high. The river Maritza, being navigable as far as Adrianople for small craft, contributes to the commercial prosperity of the town. The port is Enos, which retains its ancient name, and stands on one side of the bay, into which the Hebrus flows. The manufactures of Adrianople are silk, woollen, and cotton stuffs; it has also establishments for dyeing, and distilling rose-water and other perfumes, and for tanning leather. Among its chief exports are fine wool, leather, wax, &c. Chishull remarked in his time, 'that about Adrianople grows an excellent red wine.' In the campaign of 1829, when the Russians invaded Turkey and crossed the Danube and the Balkan, they advanced under General Diebitsch as far as Adrianople, when peace was concluded in September 1829. [See Balbi, *Abrégé de Géographie*, 1833. Also, Ersch and Gruber.]

ADRIAN'S WALL. [See Roman Wall.]

ADRIATIC SEA, Hadria, or more commonly called by Latin writers the Upper Sea, (*mare superum*,) was the ancient name of the Gulf of Venice. The term Adriatic (or Atriatic, which Pliny says was the earlier form of the name) was derived from the city Adria [see Adria.] The name Adria is used by Herodotus, but he seems to apply it perhaps rather to the country on the coasts of this gulf. The Adriatic Sea is called by Greek writers the Ionian Bay or Gulf, forming part of the Ionian Sea; but whence the epithet Ionian was derived, there is no satisfactory account.

Horace makes the Hadria wash the Calabrian coast, and Thucydides says (I. 24,) that Epidamnus, now Durazzo, lies on your right as you sail into the Ionian Gulf. According to this, the Adriatic and Ionian Sea would appear to be co-extensive, at least towards the north.

The following is Strabo's account (Casaub. Ed. p. 316.)—'After Apollonia come Balliace and Oreon, and its port Panormus, and the Ceraunian mountains (now Cape Linguetta), which are the commencement of the Ionian Gulf and the Adriatic. The mouth or strait indeed belongs to both, but the Ionian is the name of the *first* part of this sea, and the Adriatic of the *inner* part up to its recess; and now it is the name even of the *whole* sea.'

ADULA'RIA is the name given by mineralogists to the ornamental stone called by lapidaries *moonstone*, on account of the play of light exhibited by the arrangement of its crystalline structure. The term is derived from Mount Adula, in the country of the Grisons, in Switzerland. It is a very pure limpid variety of the common mineral, *felspar*, and is composed of 64 per cent. of silica, 20 of alumine, 2 of lime, and 14 of potash, according to the analysis of Vauquelin. It is found abundantly on the Alps, and on Mount St. Gothard; but the best are from Ceylon, and a very fine specimen has been sold for as much as 30*l*.

ADU'LE corresponds to the modern Zulla, on the west coast of the Red Sea [see Abyssinia]. Zulla is in the recess of a small bay, named Annesley's Bay, and in N. lat. 15° 35′. It is a matter of some curiosity to determine with precision what spot corresponds to the Adule of Cosmas, who was a merchant of the sixth century of the Christian era, and has preserved in his book, entitled *Christian Topography*, a copy of a Greek inscription which he found at this place. Adule at this period was the port of Axum, where merchants traded for ivory and slaves, just as they now do at Massowa, on the same coast—so little are things changed, in many parts of the world, after the lapse of centuries. When Mr. Salt was in Abyssinia he was prevented from visiting Zulla; a friend of his who went there was also prevented by the jealousy of the natives from visiting the remains. All however agreed in saying that there were remains at this place. The name Zulla is sometimes pronounced Thulla, and Adule may readily be admitted to correspond so far as to strengthen the probability of their both designating the same place. Mr. Salt adds, that some of the natives pronounced the name Azoole, which is clearly the same as Adule. D'Anville, in his map of the Red Sea, places Adule at Arkeeko on the same coast, and about 22′ farther north than Zulla. The inscription was found, according to Cosmas, partly on a throne of white marble, and also on a tablet which stood behind the chair, and, as far as we can collect, was a different kind of stone. Till Mr. Salt discovered the inscription at Axum, and compared it with the latter part of the inscription of Adule, it had been supposed that the *entire* inscription on the latter monument referred to one and the same personage, whereas it is now pretty certain that Cosmas has made two inscriptions into one, and caused no little difficulty to the learned world. These inscriptions are really curious, considering the *place* where they were found and the language in which they are written: they may be seen in Montfaucon's *Collectio Nova Patrum*, Paris, 1706, folio, vol. ii., p. 141, in Fabricius' *Bibliotheca Græca* tom. ii., and Chishull's *Antiquitates Asiaticæ*.

The first part of the inscription refers to the third Ptolemy, called Euergetes or the *good doer*, King of Egypt, who, according to the testimony of the stone, was supplied 'with elephants from the Troglodytæ and the Ethiopians, which his father (Ptolemy II.) and himself first hunted in these regions, and having taken down to Egypt, adapted to the use of war.' This Ptolemy reigned from B.C. 247 to 222. The second part of the inscription is in the first person (the first part being in the third), and appears to record the triumphs of some Ethiopian king, whose name does not appear, over many of the people of Ethiopia, and as far as the borders of Egypt. This passage alone is sufficient to show that the second part of the inscription cannot refer to the same person as the first part; for Ptolemy's conquests extended from Egypt to Ethiopia, and not from Ethiopia to Egypt. The second part commemorates also the conquests of this Ethiopian king over some of the nations of Arabia; and we find (which tends to confirm the general accuracy of the facts) that several names are mentioned which we can still recognize in Africa. Among others, the stone speaks of the *Semenæ* or Samene, the people of *Samen* [see Abyssinia], 'a nation dwelling beyond the Nile, in mountains difficult of access, and snow-covered, wherein all through the year there is ice and very deep snow, so that a man will sink up to the knees—these, having crossed the river (says the Ethiopian king), I subdued.' The mountains are clearly the Samen, and the river is the Tacazzé. [See Clinton's *Fasti*, part ii., p. 382.]

ADULT-SCHOOLS are establishments for instructing in reading and other branches of knowledge those persons who have not been educated in their youth. They are designed to meet the wishes of people who are no longer contented to remain uninstructed, and who do not think that the privation of an early education should necessarily entail upon them the evil of perpetual ignorance.

It has generally been found that those who are desirous of acquiring knowledge, and of attaining to a higher state of mental improvement, will better understand and practise the duties of the social system. The results of actual experience on an extended scale have shown the advantages of adult-schools to be even greater than could have been anticipated. They have uniformly worked good, by improving the intellectual and moral condition of persons under their influence.

The first school avowedly established for the purpose of instructing adults was formed in 1811, through the exertions of the Rev. T. Charles, a clergyman in Merionethshire. Some grown-up persons had previously attended his parish sunday-school, but they showed a disinclination to learn with children, and this circumstance led to the adoption of more extended views for their benefit. Considerable success both in the number and progress of the pupils, and their improved conduct and character, caused the establishment of other adult-schools throughout Wales.

About the same time, and without any concert or connexion with the schools in Wales, a school was established at Bristol through the instrumentality of W. Smith. This person, 'who collected the learners, engaged the teachers, and opened the two first schools in England for instructing adults exclusively, in borrowed rooms, and with borrowed books[*],' was the door-keeper to a dissenting chapel. He devoted three out of eighteen shillings, his weekly earnings, to defray the expense of giving to his brethren the means of studying the Scriptures, and of obtaining knowledge from other sources. A short time after these first efforts were made, a society was formed for the furtherance of his benevolent views. In the first report of this society, dated April, 1813, it was stated, that 222 men and 231 women were already receiving education. Adult-schools were soon afterwards established in different parts of the kingdom, at Uxbridge, Norwich, Ipswich, Sheffield, Salisbury, Plymouth, and other places.

These institutions are in general conducted in an excellent spirit. The different committees for their management are usually composed of individuals of various religious persuasions. No party feelings are sought to be instilled—no particular creeds are authoritatively imposed; but means are offered to the persons who attend for inquiring and judging for themselves, and their minds are left perfectly unbiassed.

It has been found that many of the uneducated are unwilling to attend the public schools, in consequence of a dislike to expose their ignorance. To meet this difficulty, the plan of *private* schools has been adopted in Bristol and elsewhere. A few individuals living near to each other meet at their own dwellings, or at some more suitable place, where they are instructed by their benevolent teachers. We have had an opportunity of knowing how much pleasure and profit has been gained from this mode of instruction in a school at Bath now conducted by a few ladies, who, on stated evenings in the week, devote two or three hours to teaching some of the uneducated of their own sex. A poor widow woman, sixty-six years of age, distressed in mind and body, earning a precarious subsistence and wholly ignorant even of the rudiments of reading, commenced attendance on this school three years ago; in a few months she learned to read, and is now unable adequately to express her sense of the happiness she derives from this acquisition. This is not, however, a solitary instance where a person has acquired the difficult art of reading in old age. Many verging on the grave have gladly availed themselves, in the last few months of their existence, of the means afforded them of reading for themselves the hopes and promises held out by the Scriptures. In a few years, perhaps, by a system of mutual instruction, these adult-schools may be made the means of continuing the education begun in youth; for there will, it is hoped, soon be but a small number of adults who will not have acquired the art of reading in their childhood. Scarcely twenty years back (1814), it was reckoned that England alone contained 1,200,000 adults who could not read. In the first annual report of the society in Edinburgh for the support of Gaelic schools, it is stated that 300,000 persons in the Highlands and islands of Scotland could not read either Gaelic or English; and that in the islands, among a population of 14,056, only 1836 could read. We are enabled to add the following particulars respecting an experiment in adult education tried with success by Dr. Johnstone, at Edgbaston Hall, near Birmingham. This school was established about 1815; and the only expense incurred by the individual with whom the plan originated, is that of providing a room once a week, with fire and candle. There are now forty members—more than half the labouring population of the parish—of all ages from eighteen to seventy. The teaching is confined to reading and writing; but there is a prosperous and well-conducted benefit society connected with the institution. The management of the school and the benefit society is in the hands of the men themselves. This point has always been a great object with the founder of the school. The men teach each other; and the affairs of the benefit society are directed by a committee chosen by the members generally. The school assemble once a week, on Sunday evening, for two hours; but the men often go on with their lessons at home in the week days. It is found that a man who is quite ignorant of reading will generally acquire sufficient knowledge to enable him to read with pleasure to himself in the course of six months. It may appear somewhat strange that the men are fonder of writing than of reading. In truth, they show wonderful perseverance in plodding through endless copies, from the large text down to the small hand. In many instances the members of the school have been able to turn their acquirements, small as they are, to very good account. A man who has had the office of standing overseer of Edgbaston parish for seven years, was qualified in the adult school. When he entered it he could neither read nor write. The moral effect of the school has been most satisfactory. A man who has been a leading member for several years, was an habitual tippler before he entered the school; he is now always sober. Though the school has been in existence for seventeen years, there have been only three or four cases of members applying for parish relief during the whole time; and these cases happened in the first period of its establishment. One member has been even reclaimed from pauperism. He was formerly a constant burden on the parish; he is now, however, quite independent of assistance, and has lately opened a huckster's shop.

Adult-schools have likewise been established at Philadelphia and New York. In the latter city there is one opened for adults among the black inhabitants.

ADULTERY is the offence of incontinence between two married persons, or between two persons, one of whom is married. In the latter case it is called single, in the former, double adultery.

This crime was punished by the Jewish law with death; but it must be remembered that the kind of adultery which by the Mosaic law constituted a capital crime, was not every violation of chastity of which a married person, whether husband or wife, may be guilty; but only the sexual connexion of a wife with any other man than her husband. This distinction was analogous to the whole system of the Jewish marriage-law; by which the husband and wife had not an equal right to restrain each other from infidelity; for the former might marry other wives, or take concubines and slaves to his bed, without giving his first wife a legal right to complain of any infringement of her matrimonial rights. The punishment, however, of incontinence in a married *woman* with a stranger was, by the Levitical law, death by stoning, both in the case of the stranger and the adulteress. (Levit. xx. 10, and Michaelis' *Mosäisches Recht.*) By the Athenian law, the husband might kill the adulterer, if he detected him in the act of dishonouring him (Lysias's *Oration on the Death of Eratosthenes*). Under such circumstances, the Code Napoleon expressly authorizes the husband to kill both the offenders.

The Roman law corresponds with the Hebrew law respecting the distinction between the infidelity of the husband and the wife. The civilians define adultery to be the violation of another man's bed (*violatio tori alieni*); so that it appears from the definition itself, that the infidelity of the husband could not constitute the offence. The more ancient laws of Rome, which were extremely severe against the offence of the wife, were silent as to that of the husband. By an old law, an adulteress was to be slain by her husband and his relations (*adulterii convictam vir et cognati uti volent, necanto*). At a later period, by the Lex Julia, adultery in the wife was punishable by her banishment or transportation into some remote island; she also forfeited half her dowry and a third part of her goods; and the adulterer forfeited half his goods to the public use. But although by the Julian law adultery was not punishable with death by a legal sentence, the father of the adulteress was permitted to kill both her and her paramour; and in some cases, the husband had the same power. In the reign of Constantine, adultery in the wife became, by the Roman law, a capital offence; and continued to be so until the time of Justinian, who introduced some mitigation of the punishment.

By the canonical law, however, which is now more or less interwoven into the municipal laws of most Christian countries. adultery is defined to be the violation of conjugal fidelity; and, consequently, the incontinency of the wife and husband stand upon the same foundation. Hence arises the distinction above alluded to between a single and double adultery.

---

[*] Pole's History and Origin of Adult-Schools.

Double and single adultery are punishable with various degrees of severity in most of the countries of modern Europe; but it is believed that in none of them, at the present day, is either of these offences capital.

There are some faint traces of the punishment of adultery as a crime in very early periods of the history of English law. Lord Coke says, that in ancient times it was within the jurisdiction of the sheriffs' tourns and courts-leet, and was punished by fine and imprisonment (3 Inst. 306): but at the present day, adultery is not the subject of a criminal prosecution; and in the temporal courts, this offence is exclusively confined to the cognizance of the Ecclesiastical Court, according to the rules of the canon law. Instances of criminal prosecutions in the spiritual courts for adultery are extremely rare; and if instituted to the conviction of the parties, the infliction of a slight fine or penance 'for the benefit of the offender's soul' (*in salutem animæ*), as it was termed, would be the only result. In the year 1604 (2 James I.) a bill was brought into parliament 'for the better repressing the detestable crime of adultery.' This bill went through a committee in the House of Lords; but, upon being reported, it was suggested to the House that the object contemplated by the measure was the private interest of some individuals, and not the public good; whereupon the bill was dropped. [See *Parl. History*, vol. v. p. 88.] During the Commonwealth, adultery, in either sex, was made a capital felony [see Scobel's *Acts*, part ii. p. 121]; but at the Restoration, this law was discontinued.

Adultery, however, comes under the cognizance of the temporal courts in England as a private injury to the husband, though not as a public wrong. Thus a man may maintain an action against the seducer of his wife, in which he may recover damages as a compensation for the loss of her services and affections in consequence of the adultery. For the particular rules and limitations by which this action is governed, see Selwyn's *Nisi Prius*, title 'Adultery.'—[See DIVORCE.]

ADVENT, literally, the approach or coming, is the space of four weeks preceding Christmas, appointed in the English and other christian churches to be kept holy in celebration of the approach of our Saviour's nativity or manifestation. Anciently, the season of Advent consisted of six weeks, and, commencing therefore about Martinmas, used to be called the *Sancti Martini Quadragesima*, or the Forty Days' Lent of St. Martin. It is still of this duration in the Greek church. The first Sunday in Advent, commonly called Advent Sunday, is now the Sunday, whether before or after, which falls nearest to St. Andrew's day (the 30th of November). Marriages are not allowed to be solemnized from the commencement of Advent to the end of the octaves of Epiphany, that is the 14th of January, except by special license.

ADVENTURE BAY, is situated on the south-east coast of New Holland, in latitude 43° 21′ south, and longitude 147° 29′ east. This bay was first discovered by Captain Furneaux in 1773, and was named by him after the ship which he commanded, and which formed part of the expedition under the orders of Captain Cook. The anchoring ground is good and well sheltered, and the neighbouring shore furnishes abundance of wood and water which are easily procured. At the head of the bay is a beautiful sandy beach, two miles long, formed by particles continually washed by the sea from a very fine white sand-stone that bounds the shore. Behind this beach is a level plain, containing a lake with brackish water, where abundance of bream and trout are found. The shores of the bay in other parts, are hilly, and the whole district is very thickly wooded, presenting to view in every direction, a perfect forest of tall trees, with thickets of shrubs beneath, which render it almost impassable. The soil is not deep but rich, consisting of black, vegetable mould. No considerable stream has been discovered in the neighbourhood of the bay. Several small rivulets trickle between the hills, and uniting together form brooks. The spot is occasionally visited by some of the wandering aborigines of the island, who never remain long in one place, but move about in quest of food, having not yet adopted the arts of cultivation or of domesticating animals. The animal principally found in these wilds is the kangaroo, in hunting which the natives show considerable activity. Brown hawks, crows, paroquets, pigeons, and a variety of small birds, frequent the woods, which are also infested by large black snakes and lizards. Insects are very numerous and troublesome; among these are musquitoes and a large black ant, the pain of whose bite is intolerable for a short time. The bay is visited periodically by an abundance of fish of various kinds. Adventure Bay was visited by Captain Cook in 1777, and subsequently (in 1788 and 1792) by Captain Bligh, for the purpose of obtaining wood and water (see *Cook's Third Voyage*, vol. i., p. 93—117. *Flinder's Voyage*, vol. i., introduction. *Bligh's Voyage to the South Seas*, p. 45—54. *Voyage D'Entrecasteaux*, redigé par M. de Rossel, tom. i., p. 48.

ADVENTURE, BILL OF, is a writing signed by a merchant, stating that the property of goods shipped in his name belongs to another, the adventure or chance of which the person so named is to stand, with a covenant from the merchant to account to him for the produce. In commerce, an adventure is defined a speculation in goods sent abroad under the care of a supercargo, to dispose of to the best advantage for the benefit of his employers.

ADVERB, in grammar, the name given to a class of words employed with verbs, adjectives, &c., for the purpose of qualifying their meaning, just as the adjective itself is attached to substantives. In the English language a very large majority of adverbs are distinguished by the termination *ly*, which in the Anglo-Saxon has the fuller form *lice*, and in German, *lich*. Our own language possesses the same suffix in the form *like*, as *godlike*, *gentlemanlike*. These, however, and many other words in *ly* are adjectives, as *manly*, *ugly*; and it is difficult to draw the line between these two classes, many words, especially in the older writers, being used indifferently for both [see ADJECTIVE]. The word to which the adverbial suffix *ly* is added is generally an adjective, but occasionally the adjective has become obsolete in the present form of our language, and must be sought in the Anglo-Saxon. Thus *early* is derived from the Anglo-Saxon *aer*, which indeed still appears in the now poetical forms *ere*, and the superlative *erst*. But though the termination *ly* is derived from the Teutonic portion of our language, it has been applied most freely to adjectives of Latin origin, as *publicly*, *privately*; and with these may be classed the adverbs from adjectives in *ble*, as *horribly*, *agreeably*, in which the liquid belongs at once to the adjective and the suffix. An important class of adverbs are formed by prefixing the old Saxon preposition *an* or *on* to nouns, in which a careless pronunciation afterwards left nothing but the vowel *a*, as *on fote*, now *a-foot*. Lastly, we have an interesting though ludicrous formation depending upon alliteration, *helter-skelter*, *hurry-skurry*, *pell-mell*, *higgledy-piggledy*, &c. The same love of alliteration, which is said to have formed an important element in Anglo-Saxon versification, has also given rise to some adjectives and substantives, as *hum-drum*, *slip-slop*, *tip-top*, *tittle-tattle*, *hurly-burly*.

ADVE'RTISEMENT. In the English, Scotch, and Irish newspapers, and other periodical works, there are annually published more than a million of announcements, which, whatever be their peculiar character, are known by the general name—Advertisement. Each of these Advertisements now pays a duty of 3*s.* 6*d.*; and the gross produce of the tax is about 170,000*l.* The charge for an Advertisement necessarily depends upon its length, and most newspapers have a scale per line. The price of the shortest advertisement, and the increasing price according to length, are regulated, or ought to be, by the number circulated of the work in which it is printed. Advertisements, generally, supply a fund by which newspapers are supported; for, in most cases, the price at which the newspaper is sold is insufficient to pay the cost of the stamp, the paper, the printing, and the expenses of management. Many newspapers have greatly enlarged their size of late years, to allow of the insertion of a large number of Advertisements. Thus one copy of the Times in the whole of the year 1831 contained 4,588 square feet, while one copy of the Star contained only 2,882 square feet;—the Times is a great advertising paper, and the profits of Advertisements allow the proprietors to make their paper nearly twice as large as the Star, although the price is the same. In the greater number of Advertisements the duty of 3*s.* 6*d.* constitutes a tax of 100 per cent. upon the price received for their own benefit by the proprietors of a newspaper;—and there is no doubt that if the tax were materially reduced, the number of Advertisements would be greatly increased. The increase would, however, demand greater attention to classification; and particular publications would, probably, adapt themselves to particular classes of Advertisements. If it were not so, the increase would have an injurious operation upon the efficiency of Advertising as a means of commercial information. The first English Advertisement which can be found, is in the "Impartial Intelligencer," for 1649, and relates to stolen horses. In the few papers published from the time of the Restoration to the imposition of the Stamp Duty, in 1712, the price of a short Advertisement appears seldom to have exceeded a shilling, and to have been sometimes as low as sixpence. [See Nichols's *Literary Anecdotes*, vol. iv.]

ADVICE, in its legal signification, has reference only to bills of exchange. The propriety of inserting the words 'as per advice,' depends on the question whether or not the person on whom the bill is drawn, is to expect further directions from the drawer. Bills are sometimes made payable 'as per advice;' at other times 'without further advice;' and generally without any of these words. In the former case the drawer may not, in the latter he may, pay before he has received advice.

Advice, in commercial language, means information given by one merchant or banker to another by letter, in which the party to whom it is addressed is informed of the bills or drafts which have been drawn upon him, with the particulars of date, &c., to whom payable, &c., and where.

ADVOCATE, from the Latin *advocare*, to call in aid. Among the ancient Romans, an advocate was a person skilled in the laws. The origin of advocates in Rome was derived from an early institution, by which every head of a patrician house had a number of dependants, who looked up to him as a protector, and in return owed him certain obligations. This law established the relation of *advocate*, or patron, and client. As it was one of the principal and most ordinary duties of the patron to explain the law to his client, and to assist him in his lawsuits, the relation was gradually contracted to this extent.

In early periods of the Roman republic, the profession of an advocate was held in high estimation. It was then the practice of advocates to plead gratuitously; those who aspired to honours and offices in the state taking this course to render themselves distinguished amongst the people. As the simplicity of ancient manners gradually disappeared, the services of Roman advocates became venal. At first it appears that presents of various kinds were given as voluntary acknowledgments of the gratitude of clients for services rendered. These payments, however, gradually assumed the character of debts; and at length became a kind of stipend periodically payable by clients to those of the patrician order who devoted themselves to pleading. In this form, it became a heavy oppression, and was always considered to be an abuse. At length the Tribune Cincius, about 200 years before Christ, procured a law to be passed called from him Lex Cincia, prohibiting advocates from taking money or gifts for pleading the causes of their clients. At the time of Augustus, this intended prohibition seems to have become inefficient and obsolete; and a decree of the senate was then passed by which the Cincian law was revived, and advocates were commanded to plead gratuitously, under a penalty of four times the amount of the fee they received. Notwithstanding these restrictions, it clearly appeared that the constant tendency was to recur to a pecuniary remuneration; for in the time of Claudius we find a law restraining advocates from taking exorbitant fees, and fixing as a *maximum* the sum of 10,000 sesterces for each cause pleaded, which would be equivalent to about 80*l*. sterling. [Tacit. *Ann.* xi. 5.] Some years afterwards, Pliny mentions a decree passed in his time, that all litigants in courts of justice, previously to the hearing of their causes, should take an oath that they had neither given, promised, nor secured any reward or money to any person employed as their advocate.

In later periods, as the Roman law diffused itself over great part of Europe, these restrictions upon the pecuniary remuneration of advocates, which must always have been liable to evasion, entirely disappeared in practice; and the payment of pleaders for conducting causes in courts of justice resembled in substance the payment of any other services by those who derived benefit from them. In form, however, the fee was merely an honorary consideration (*quiddam honorarium*), and was generally, but not necessarily. *pre-numerated*, or paid into the hands of the advocate before the cause was pleaded. It was a rule, that, if once paid, the fee could never be recovered, even though the advocate was prevented by death or accident from pleading the cause; and where an advocate was retained by his client at an annual salary (which was lawful and usual), the whole yearly payment was due from the moment of the retainer, though the advocate died before the expiration of the year. [See Heineccii *Elementa Juris Civilis*, p. 132.] Manifest traces of this practice are still to be found in all countries into which the civil or Roman law has been introduced; and are also clearly discernible in the rules and forms respecting fees to counsel at the present day in England.

In countries where the Roman law prevails, the pleaders in courts of justice are still called advocates; their character, duties, and liabilities, being extremely various under different governments. In Scotland, the faculty of advocates consists of pleaders or counsel, admitted, upon an examination, to practise before the Courts of Session, Justiciary, and Exchequer; they are also entitled to plead in the House of Lords in England upon appeals from the Scotch courts.

Advocates in English courts are usually termed *counsel*, and we therefore refer to that title for a particular account of their history, privileges, and duties.

The *Lord Advocate*, or *King's Advocate*, is the principal crown lawyer in Scotland. Previously to the Union, he was one of the great state officers, and sat in parliament by virtue of his office, without election. His duty is to act as a public prosecutor, and to plead in all causes in which the crown is interested, and particularly in criminal cases. Originally this officer had no power to institute criminal prosecutions, except at the instance of injured parties; but in the year 1597, he was expressly empowered to prosecute crimes at his own discretion.

ADVOCATES' LIBRARY. The idea of establishing a library, for the use of the Faculty of Advocates in Scotland, seems first to have been entertained a few years before the Revolution. The author and active promoter of the plan was Sir George Mackenzie of Rosehaugh. Although we have before us that gentleman's inaugural oration, which he pronounced when the library was first opened, as well as several other papers relative to the subject, we cannot well fix the precise date when Sir George's scheme was first approved and adopted by the faculty as a body. In the Latin inaugural oration, which is said to have been delivered in 1689, is the following passage:—'This is the fifth year since the Faculty of Advocates resolved, from gifts of benefactors, and from subscriptions of candidates, to found and establish a library, consisting merely of the works of lawyers, and such other works as tended to the advancement of jurisprudence.' We may conclude from this that the idea was adopted by the faculty in 1684 or 5; but Mr. Alexander Brown, who was librarian to the Faculty of Advocates in 1772, says in the preface to *Ruddiman's Catalogue*, which he edited, 'The plan of forming a public library appears to have been adopted by the Faculty of Advocates about the year 1680.'

At first, the Advocates' Library had no fixed fund, but subsisted and increased by means of donations, not from advocates only, but also from other individuals, and from such sums as the faculty, from time to time, placed at the disposal of the curators. Thus then it happened that although the Advocates' Library, strictly speaking, belonged to the Faculty of Advocates as an exclusive body, it still was early considered as a public library, and was open to the public. This characteristic has rendered the institution very popular, and at the same time promoted its increase. In the year 1700 the greater part of the collection was consumed by fire. During the first nine years after its restoration the library must have increased considerably, since, in the eighth year of Queen Anne's reign, it obtained the privilege of receiving a copy of every new book which, by chapter nineteen of the acts of parliament of that year, was conferred on it, with eight other libraries. Of these, five were Scotch libraries; and the disproportionate privilege may have originated in the desire of the legislature to grant some benefit to Scotland at the time of the Union. Shortly after the Union with Ireland, the same privilege was granted to two Irish libraries.

The whole number of volumes now contained in the library is estimated not to exceed 150,000. Still the Advocates' Library is by far the largest, and also the most valuable in Scotland. In Great Britain there are probably only two libraries, viz., the British Museum and the Bodleian, that out-number it. As might be expected, the collection of law books is very large, but far more complete in ancient than in modern works. Many important modern works of foreign jurisprudence are still wanting. The historical collection is exceedingly valuable, containing almost every work of importance that has been published in England, France, Italy, Spain, Portugal, Denmark, and Sweden: the historical department alone comprises upwards of 20,000 vols. The collection of Greek and Roman classics is choice and extensive; the same may be said of that of modern poetry and *belles lettres;* there is also a very considerable divinity collection, and one of voyages and travels. Science has been much neglected in this library, and this department is insignificant. A collection of Spanish books containing nearly 3000 vols., was, in the year 1824, bought from a London bookseller, at very great expense. There is also a collection of MSS., by no means a large one; several of them are said to be important and available for Scottish history. They are, however, chiefly of local interest. In the year 1825 about 100 vols. of Icelandic MSS. were purchased from Professor Magnuson of Copenhagen. In the following year Mr. Erskine, late of Bombay, made a donation to the library of a few valuable Persian and Sanscrit MSS. There are also a few MSS. of Latin classics, but of no great importance. There is a beautiful MS. of the Hebrew Bible lately purchased in Germany: it is in two large folio volumes: the Pentateuch has, besides the Original, also the Chaldaic paraphrase.

The building which contains the Advocates' Library is not only very confined, but also dark and inconvenient. The historical department is at present separated from the rest, and placed in a very large room built about twelve years ago for the use of the Advocates, but subsequently bought by the writers to the signet, whose library is situated immediately below. A new structure is now building for the reception of the historical department. As far as concerns this department, the building will be unobjectionable in most respects; but the rest of the Advocates' Library is distributed in *eleven* rooms, being for the most part vaults or cellars below the old parliament-house, in which the court of session is now held. Some of these rooms are completely dark, and lighted by lamps; others have only borrowed light; and only three are properly lighted. In addition to the rooms we have mentioned, there is a warehouse belonging to the Faculty of Advocates situate underground in the north-west corner of the Royal Exchange: amongst other things this warehouse contains a very valuable collection of German Dissertations, for the most part productions of distinguished scholars, amounting to upwards of 100,000. This collection was bought at a cheap rate for the library by Sir William Hamilton, professor of history in the University of Edinburgh.

The Advocates' Library is governed by five curators, of whom one goes out of office by rotation every year, and one is chosen in his stead from among the body of the Faculty of Advocates. Under the curators there are, a keeper of the library, an assistant keeper, and two or three assistants. When the funds of the Faculty had somewhat increased, by raising the fees of entrants, the Faculty during a considerable period set apart 100*l.* from the fees of each entrant, and placed the amount at the disposal of the curators. The average of entrants each year has been stated to be seventeen; and thus the annual income of the library at the period here alluded to, along with some additional fees, amounted to 1780*l.* In the year 1728 this system was altered, and the treasurer of the Faculty was ordered to pay 600*l.* annually out of the Faculty's income to the curators for the use of the library. This system still continues.

As to *ease of access*, there is no public institution in Great Britain, and very few in Europe, managed with greater liberality than the Advocates' Library; but we ought in candour to admit that this is a somewhat equivocal compliment. It is, however, surprising, that, although it has become almost a sort of bazaar, or a common lounging-place for a number of idle people, the library has suffered very little in consequence. Any stranger arriving in Edinburgh is admitted without introduction; but some introduction is required for habitually resorting to, and reading in the library. Even borrowing of books is subject to very slight restriction. Each advocate enjoys the privilege of borrowing twenty volumes (formerly twenty-five) at a time; if he wishes to favour an individual, who is not a member of the Faculty of Advocates, with the loan of a book, he has only to sign the initials of his name in the journal or receipt-book, as a security. As there commonly are about two hundred Advocates residing in Edinburgh, and as they are, almost without exception, remarkably liberal in lending books, it is in that city by no means difficult to obtain a free use of a very extensive library.

Of the librarians, or, as they are called in Scotland, 'Keepers of the Advocates' Library,' the two first only deserve to be mentioned as men of literary attainments, viz., Thomas Ruddiman and David Hume. The great philosopher and historian succeeded Ruddiman in the year 1757, but resigned in 1757, and seems to have been but indifferently pleased with his situation. The place of assistant-keeper of the Advocates' Library was, in the year 1825, offered to the eminent philologist, the late Professor Rask, of Copenhagen, with a salary of 150*l.* a-year. This offer was declined. It was likewise offered to several other persons, amongst whom was Professor Benecke, of Göttingen.

While the court of sessions sits, the Advocates' Library opens at nine o'clock in the morning, and shuts at four o'clock, p.m.: during vacation it is open from ten till four.

ADVOWSON. The right of presenting a fit person to the bishop, to be by him instituted to a certain benefice within the diocese which has become vacant. The person enjoying this right, is called the *patron* of the church, and the right is termed an advowson (*advocatio*), because he is bound to advocate or protect the rights of the church, and of the incumbent whom he has presented.

As this patronage may be the property of laymen, and is subject to alienation, transmission, and most of the changes incidental to other kinds of property, it is obvious that it would be liable to be misused by the intrusion of improper persons into the church, if the law had not provided a check upon abuse, by giving to the bishop a power of rejecting the individual presented, for just cause. The ground of his rejection is, however, not purely discretionary, but is examinable at the instance, either of the clergyman presented, or of the patron, by process in the ecclesiastical and temporal courts. [See DUPLEX QUERELA. QUARE IMPEDIT.]

According to the best authorities, the appointment of the religious instructors of the people within any diocese formerly belonged to the bishop: but when the lord of a manor, or other considerable landowner, was willing to erect a church, and to set apart from his possessions a sufficient portion of land or tithe for a perpetual endowment of it, it was the practice to give to the founder and his heirs, in acknowledgment of his beneficence, the right of nominating a person in holy orders to be the officiating minister, as often as a vacancy should occur, while the right of judging of the spiritual and canonical qualification of the nominee was reserved, as before, to the bishop.

This seems to be the most satisfactory account of the origin of *advowsons* and *benefices*, and it corresponds with many historical records still extant, of which examples may be seen in Selden's *History of Tithes*. It also serves to explain some circumstances of frequent occurrence in the division of parishes, which might otherwise appear anomalous or unaccountable. Thus the existence of detached portions of parishes, and of extra-parochial precincts, and the variable extent and capricious boundaries of parishes in general, all indicate that they owe their origin rather to accidental and private dotation, than to any regular legislative scheme for the ecclesiastical subdivision of the country. Hence, too, it is frequently observable, that the boundaries of a parish either coincide with, or have a manifest relation to, manorial limits. The same connexion may, perhaps, have suggested itself to those who have had opportunities of noticing the numerous instances to be seen in different parts of England, in which the parochial place of worship is closely contiguous to the ancient mansion of its founder and patron, and within the immediate inclosure of his demesne.

As an illustration of the respect inculcated in early ages to the patron of a church, we find that the canons of the church permitted him alone to occupy a seat within the chancel or choir, at a time when that part of the building was partitioned off from the nave, and reserved for the exclusive use of the clergy. [See Kennett's *Paroch. Antiq. Glossary*, tit. "Patronus."]

An advowson which has been immemorially annexed to a manor, or to other land, is called an *advowson appendant*, and is transmissible by any conveyance which is sufficient to pass the property in the manor or land itself. It may, however, be detached from the manor, and is then termed an *advowson in gross*, after which it can never be re-annexed, so as to become appendant again.

An advowson is regarded by the law in the double light of a temporal property, and a spiritual trust. In the former view, it is a subject of lawful transfer by sale, by will, or otherwise, and is available to creditors in satisfaction of the debts of the patron. It may be aliened for ever, or for life, or for a certain term of years; or the owner may grant one, two, or any number of successive rights of presentation on future vacancies, subject always to certain restrictions imposed by the law, for the prevention of corrupt and simoniacal transactions.

On the other hand, the spiritual trust which is attached to this species of property is guarded and enforced by very jealous provisions. We have already seen, that the appointment of a duly qualified incumbent is secured, as far as the law can secure it, by requiring the sanction of the bishop to his admission; and although this sanction is, in fact, very rarely withheld, yet it cannot be doubted that the existence of such a check is essential to the well-being of the church. In order more effectually to guard against the danger of a corrupt presentation, the immediate right to present is absolutely inalienable, as soon as a vacancy has actually occurred; and on a similar principle, a purchase of it during the mortal sickness of the incumbent is equally prohibited. [See SIMONY.]

We have seen, that when the proprietor of an advowson exercises his patronage, three persons are immediately concerned: the proprietor, the clergyman who is presented, and the bishop in whose diocese the living is situate; or (in the language of lawyers) the *patron*, the *clerk*, and the *ordinary*. The presentation is usually a writing addressed to the bishop, alleging that the party presenting is the patron of a church which has become vacant, and requesting the bishop to admit, institute, and induct a certain individual into that church, with all its rights and appurtenances. A period of time, limited to twenty-eight days, is then allowed to the bishop for examining the qualification and competency of the candidate, and at the expiration of that time, he is admitted and instituted to the benefice by formal words of institution read to him by the bishop, from an instrument to which the episcopal seal is appended. A mandate is then issued to the archdeacon or other officer to *induct*, *i. e.*, to put the new incumbent into the actual possession of the church and its appurtenant rights; and then, and not before, his title as legal *parson* becomes complete.

It sometimes happens, that two of the three characters of patron, clerk, and bishop, (or ordinary,) are united in one person. Thus the bishop may himself be the patron; in which case it is evident, that presentation is superfluous, and institution alone is necessary. The bishop is then technically said to *collate* the clergyman to the benefice, and the advowson under these circumstances is said to be *collative*.

So the clerk may be the patron, in which case, though he cannot regularly present himself, yet he may pray to be admitted by the bishop; or he may transfer to another the right of presentation, *pro hâc vice*, before the vacancy occurs, and then procure himself to be presented.

Another instance in which the patronage and the parsonage are often found united is in *appropriations*, where, by the concurrence of all parties interested, the advowson, together with the church, its revenues and appurtenances, have in former times been conveyed to some ecclesiastical body, who thus became both the patrons and perpetual incumbents of the living, and by whom the immediate duties of cure are devolved on a *vicar*, or a stipendiary *curate*. The nature and different sorts of appropriations are treated of under that title.

There are instances of advowsons, the patrons of which have power to appoint an incumbent without any previous resort to the bishop for his aid or approbation. These are called *donative* advowsons, because the patron exercises a direct and unqualified privilege of *giving* his church to a clerk selected by himself. The only check upon the conduct of the incumbent in such cases is the power of the patron to visit, and even to deprive him, when the occasion demands it; and the right still residing in the bishop to proceed against him in the spiritual court for any ecclesiastical misdemeanour. It is the opinion of the most eminent lawyers, that donatives had their origin in the king, who has authority himself to found any church or chapel exempt from the episcopal jurisdiction, and may also, by special licence, enable a subject to do the same.

Sometimes the *nomination* is distinct from the right to present: thus, the owner of an advowson may grant to another the right to nominate a clergyman, whom the grantor and his heirs shall be thereupon bound to present. Here it is obvious that the person to whom the right of nomination is given is substantially the patron, and the person who presents is merely the instrument of his will. So, where an advowson is under mortgage, the mortgage creditor is bound to present any person who shall be nominated by the mortgagor.

It is sufficiently apparent that this species of property is coupled with a trust, in the faithful performance of which the public are deeply interested. If, therefore, upon the vacancy of a living, no successor, or an insufficient one, shall be presented, it is put under *sequestration* by the bishop, whose care it then becomes to provide for the spiritual wants of the parish by a temporary appointment, and to secure the profits of the benefice, after deducting expenses, until another incumbent shall be duly inducted. After a vacancy of six months, occasioned by the default of the patron, the right to present *lapses* to the bishop himself. On a similar default by him, it devolves to the archbishop, and from him again to the king as paramount patron; the period of six calendar months being allowed to pass in each case before the right is forfeited to the superior. A donative advowson, however, is excepted from the general rule; for there the right never lapses by reason of a continued vacancy, but the patron is compellable to fill it up by the censures of the ecclesiastical court.

When the incumbent of a living is promoted to a bishopric, it is thereby vacated, and the king, in virtue of his prerogative, has a right to present to it in lieu of the proprietor of the advowson. This singular claim on the part of the crown appears to have grown up since the Reformation, and was the subject of complaint and discussion down to as late a period as the reign of William and Mary. It is difficult to reconcile it to any rational principle, although it has been urged by way of apology, that the patron has no ground to complain, because the king might, if he pleased, enable the bishop to retain the benefice, notwithstanding his promotion, by the grant of a *commendam*: so that the patron sustains no other injury than what may result from the substitution of one life for another. It is, however, certain that, by successive promotions, the crown may, in fact, deprive the patron of his right for an indefinite time, and an instance is known to have actually occurred wherein the patron of the metropolitan parish of St. Andrew was prevented by several such exertions of the royal prerogative, from presenting to his own living more than once in 100 years. [See the arguments in the case of the vicarage of St. Martin's, reported by Sir B. Shower, vol. i. p. 468.] So that, as was truly observed by the counsel in that case, the safest course that could be adopted by an unconscientious patron, with a view to retain in his own hands the future enjoyment of his right, would be to present a clergyman whose qualities are not likely to recommend him to higher preferment.

The following cases may be selected as best illustrating the peculiar nature of this sort of property.

If a man marries a female patron, and a vacancy happens, he may present in the name of himself and wife.

Joint tenants and tenants in common of an advowson must agree in presenting the same person; and the bishop is not bound to admit on the separate presentation of either. Co-heiresses may also join in presenting a clergyman; and if they cannot agree in their choice, then they shall present in turn, and the eldest shall have the first turn.

When the patron dies during a vacancy, the right to present devolves to his executors and not to his heir: but where the patron happens also to be the incumbent, his heir, and not his executor, is entitled to present.

Where the patron is a lunatic, the lord chancellor presents in his stead; and he usually exercises his right in favour of some member of the lunatic's family, where it can with propriety be done.

An infant of the tenderest age may present to a living in his patronage, and his hand may be guided in signing the requisite instrument. In such a case it is needless to say that the guardian or other person who dictates the choice or directs the pen is the real patron; but the court of chancery would doubtless interfere to prevent any undue practice.

It is believed that the following table presents a tolerably accurate synopsis of the distribution of ecclesiastical patronage in this country.

Rectories and Vicarages in the patronage of	
The Crown	1048
Bishops	1301
Deans and Chapters	982
Universities	597
Other Colleges	146
Private Persons	6619
Chapels in private patronage	649
Total number of benefices in England and Wales	11,342

[See further, Burn's *Eccles. Law*, tit. *Advowson, Benefice, Donative.* Selden's *History of Tithes.* Gibson's *Codex*, vol. ii.]

ADVOWSONS, VALUE OF. The following plain rules for estimating the value of advowsons may be of use. The bargains which are usually made with respect to advowsons are, either for the advowson itself, *i.e.*, the right of presentation for ever, or for the right of presenting the next incumbent, *i.e.*, the next presentation. In both these cases there may be circumstances peculiar to the living itself, which fall under no general rule, but which must be considered and allowed for in valuing the advowson as a property. For example, a curate may be necessary; the parsonage-house may be in a state which will entail expenses on the next incumbent; and so on. Again, the property itself is of a nature more likely to be altered in value by the act of the legislature than the fee-simple of an estate. The following rules, therefore, give the *very highest value* of the advowson, and any purchaser should think twice before he gives as much as is found by them.

To find the value of the perpetual advowson of a living producing 1000*l.* a year, the present incumbent being forty-five years of age, and money making four per cent., we must first find how many years' purchase the incumbent's life is worth, and here we should recommend the use of the government, or Carlisle tables, (see ANNUITIES,) in preference to any other. Taking the latter, we find the annuity on a life of forty-five at four per cent., to be worth fourteen and one-tenth years' purchase; but at four per cent. any sum to be continued annually for ever is worth twenty-five years' purchase. The difference is ten and nine-tenths years' purchase, or for 1000*l.* a year, 10,900*l.*, which is the value of the advowson.

In finding the value of the next presentation only, other things remaining the same, the seller will presume that the buyer means to make the best of his bargain by putting in the youngest life that the laws will allow, that is, one aged twenty-four. The value of an annuity on such a life at four per cent. according to the Carlisle tables, is seventeen and eight-tenths years' purchase. And as we are giving the highest possible value of the advowson, omitting no circumstance which can increase it, we will suppose the next incumbent to come into a year's profits of the living immediately on his taking possession. The present value of the next presentation is the value of an annuity for 17·8 years, beginning from the present year. The rule is this: take four per cent. of the value of the present incumbent's life, or 14·1 × ·04, which gives ·564; subtract this from 1, which gives ·436; divide by 1 increased by the rate per cent., or 1·04, which gives ·419; add one year's purchase to the presumed value of the next incumbent's life, (17·8,) which gives 18·8, multiply this by the last result, ·419, which gives 18·8 × ·419, or 7·88 nearly—the number of years' purchase which the next presentation is now worth—which, if the living be 1000*l.* a year, is 7880*l.*

For the Carlisle Table of Annuities, see Milne *On Annuities*, vol. ii. p. 595. For the Government Tables, see Mr. Finlaison's *Report to the House of Commons*, ordered to be printed 31 March, 1829, page 58, column 6.

A'DYTUM, a Greek term signifying a place that may not be entered, and applied to the innermost and secret chamber of a temple.

In the ancient Egyptian temple, the Adytum is placed at the end of a series of propylæa, porticoes, and vestibules, and surrounded by galleries and chambers, which afforded every facility for concealing the mysteries of the interior. In the temples of the Greeks there is nothing corresponding to the Adytum of the Egyptian temples, unless it be the chamber which, in the Parthenon at Athens, has been called the Treasury, but which is not commonly found in other structures of the same character. The temples of the Romans, also, are without obvious adyta, though the exhumation of Pompeii has discovered to us, in the temple of Isis there, a small chamber behind and under the altar and statue of the goddess, with means of secret access, from which probably the oracular responses were delivered. We may fairly conclude that something of the same kind existed wherever oracles were delivered and the deity was not supposed to speak through an inspired representative, as in the case of the Pythia at Delphi; but no discoveries have been made in the ordinary temples of the Greeks and Romans to confirm the opinion, beyond the instance we have just mentioned.

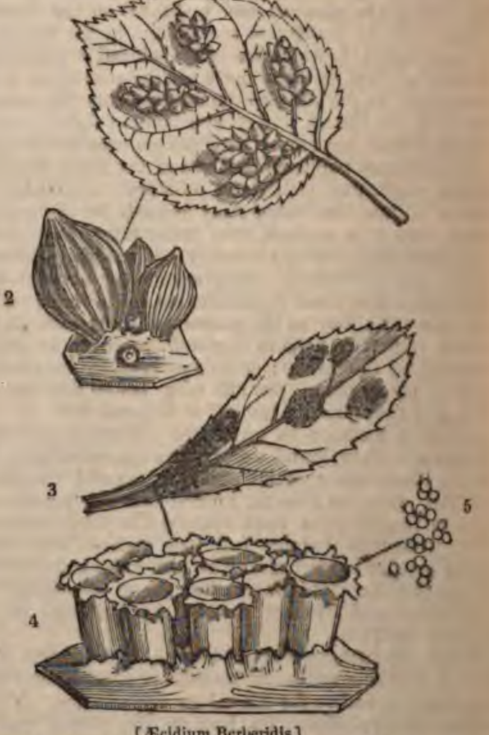
The 'most holy place,' or the Sanctum Sanctorum, the holy of holies, was the adytum of the temple of Solomon at Jerusalem, which may reasonably be believed to have been built in the form and after the manner of the temples of the Egyptians.

ÆCI'DIUM, a genus of minute parasitic plants belonging to the natural order Fungi, found in great abundance in this and other northern countries. By some modern writers it has been combined with Uredo and others; but it appears distinctly characterized by its peridium, or enveloping membrane, having a tubular form, and being altogether distinct from the cuticle of the plant on which it grows.

The species are universally parasitic upon the leaves, or flowers, or bark of living plants, where they are generated beneath the cuticle. Their structure is of the most simple kind; consisting of nothing more than a little mass of excessively minute sporules, or reproductive particles, much smaller than the finest sand, inclosed in a thin bag, of either a fibrous or reticulated structure, which in time pierces the cuticle under which it lies, gradually assumes a tubular appearance, and finally bursts at the apex for the purpose of enabling the sporules to escape.

A great many species are found upon the weeds and trees of Europe, varying in colour, size, and form. Of these the two following are among the most common.

Æcidium cancellatum, the Pear Æcidium (*Pers. Synops.* 205). This plant is often very common, in the latter months of autumn, on the back of the leaves of the cultivated pear-tree, to which it gives a singularly warted aspect. It makes its appearance crowded in little patches of a pale brown colour, which, when examined with a microscope, are seen to consist of numerous oval bodies, about a line long, rather the broadest towards the upper end. These bodies are, when young, slightly furrowed, but at a more advanced



[Æcidium cancellatum.]

[Æcidium Berberidis.]

period they divide into tough parallel fibres, which open at the sides, but do not separate at the apex. Through the passages thus formed between the fibres fall the sporules, or seed-like particles.

To inaccurate observers this species would appear an aggregation of the nests of some minute insect, for which we know it to be often mistaken. It probably does not produce any injurious effect upon the plants it attacks, for it generally makes its appearance late in the season, when the leaves have nearly completed their office for the year.

Fig. 1. in the accompanying wood-cut, represents the appearance of this species, of the natural size. Fig. 2. exhibits four of the peridia in different states of growth, and very highly magnified.

Æcidium Berberidis, the Barberry Blight (*Pers. Synops.* 209. *Greville, Scott. Crypt. Fl.* t. 97). The bright orange powder that collects upon the leaves and flowers of the common barberry consists of the sporules of this species, which are discharged from thousands of little tubular apertures, that spread in patches over all the tender parts. These apertures are the open ends of the peridia in a state of maturity, and are bordered at first by a ragged toothed membrane, which finally falls away. Among the many beautiful objects that are to be met with in the lower and more imperfect tribes of plants, it is difficult to find one more worth an attentive examination than this, which has been well illustrated by Dr. Greville in his *Scottish Cryptogamic Flora;* in that work we find the following remarks upon the popular opinion, that barberry bushes blight corn.

'This minute gastromycus has given rise to the vulgar opinion that the neighbourhood of barberry bushes is extremely detrimental to fields of wheat. It is well known that the disease called the *rust* in corn is highly injurious; but the colour of the rust and that of the present plant constitutes the only similarity between them. They belong, in fact, to two different genera, and of course cannot propagate each other. I have, nevertheless, heard creditable people affirm that they have seen the corn fail for a considerable distance round a barberry bush, while it was strong and fertile in the rest of the field. If this is in reality owing to the barberry (which I do not think), it must be attributed to some other cause than this parasitic plant.' For an account of the species which really infests corn, see PUCCINIA *graminis*.

Fig. 3. is the appearance of Æcidium Berberidis to the naked eye. Fig. 4. is a patch of the peridia very highly magnified; Fig. 5. shows the sporules still more magnified.

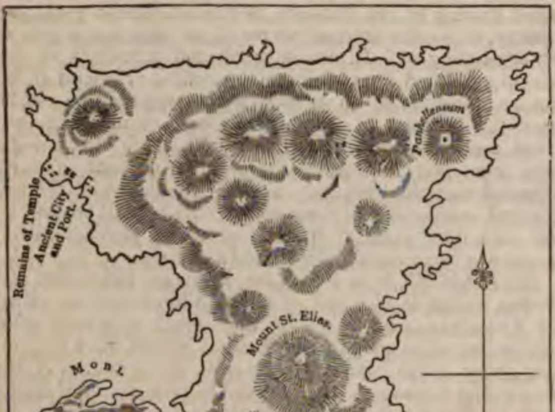
ÆDI'LES, from *ædes*, a building; the name given to certain magistrates in ancient Rome. They were four in number, two entitled *curule* ædiles, and two *plebeian*. It is difficult to mark the limit between the duties of these magistrates. The former, however, must have been originally connected with the patrician order, and elected by the *comitia curiata*. Their insignia of office were the same as those of the kings had been, viz., the purple robe called the *toga prætexta*, and the chair ornamented with ivory, or *sella curulis*. They had the care of the temples, baths, porticoes, aqueducts, sewers, and roads of the city. They presided at the religious celebrations, of which theatrical exhibitions formed an important part; and, in performing this duty, the ædiles, under the republic, were often guilty of the most lavish expenditure with the view of acquiring popularity, and thus paving their way to the higher offices of the state. The plebeian ædiles were, as their name imports, specially magistrates of the *plebes* or commonalty. They were subordinate to the tribunes of the *plebes*, and acted as judges in such causes as were referred to them by their superiors. The temple of *Ceres*, which constituted the treasury of the commonalty, was under their peculiar guardianship. They here received the fines paid for offences against the plebeian magistrates, and made a distribution of bread among the poor of their order. In the same temple, too, they preserved the public records connected with their own body, and the decrees of the senate. The care of the public buildings and streets on Mount Aventine and in the immediate neighbourhood, which in early times formed the chief residence of the commonalty, and was without the limits of the city, must have been, we may infer from their title, entrusted to the plebeian ædiles. Their persons, like those of the tribunes, were inviolable. There were other duties connected with the office of ædile, whether curule or plebeian, such as the inspection of the markets, and the superintendence of the corn trade, the examination of weights and measures, the registration of courtezans, and perhaps the general management of all matters of police in Rome and the suburbs: they had, of course, their courts for inquiring into and punishing offences connected with their office. The curule ædileship was the second in the series of honours through which the Roman candidate proceeded to the consulship; and the laws required an interval of a whole year after the close of the quæstorship, before any one could be a candidate for the ædileship. The title of ædile was known also in the municipal towns of Italy.

ÆGA'GRE (CAPRA AEGAGRA), a wild species of Ibex, called Paseng by the Persians, and believed, with great probability, to be the original source of at least one variety of the domestic goat. In the stomach and intestines of this animal are found those peculiar concretions or calculi called Bezoar stones, to which European physicians of the middle ages, the disciples of the Arabic school of medicine, imputed such wonderful properties; and which still enjoy a high reputation throughout the east, on account of their supposed medicinal virtues. For an explanation of the nature and composition of these concretions, as well as the history and description of the animal which produces them, we must refer to the articles BEZOAR and GOAT.

ÆGE'AN SEA is the name given by the Greek and Roman writers to that part of the Mediterranean now called the ARCHIPELAGO. We shall here speak of it with reference to the terms used by the classical writers when they allude either to the sea itself, the coasts that bound it, or the islands that it contains. The Ægean Sea was bounded on the north by Macedonia and Thrace, on the west by Greece, on the east by Asia Minor, and comprised between the 41st and 36th degrees of latitude. The origin of the name is doubtful; geographers derive it from different islands, or places on its shores, as Ægæ, Æga, Ægæa; or, more fabulously, from Ægæa, Queen of the Amazons, who perished there; or from Ægeus, the father of Theseus, who threw himself into it; or it may be derived, according to some, from the Greek word *αἰγὶς*, a squall, from the violent and sudden storms which render it dangerous to sailors even in the present improved state of nautical science. But the true origin of the name is unknown, and we should rather refer it to old King Ægeus than to any one else. It contains numerous islands, many of which are undoubtedly of volcanic origin. Of these the more southern are divided into two groups; one called the Sporades, or scattered islands, lying along the coast of Caria and Ionia; the other called the Cyclades, or circling islands, lying off the coasts of Attica and Peloponnesus, from which they were separated by the Myrtoan Sea, and occupying a large part of the southern Ægean. Another portion of the Ægean, lying about Icaria, one of the Sporades, was also called the Icarian Sea. The northern part of the Ægean contains fewer, but larger islands; the principal were called Chios, Lesbos, Lemnos, Thasos, and Eubœa. At the north-east corner, it communicates with the Propontis (Sea of Marmara) by the narrow strait called the Hellespont, now the Dardanelles; the Turks call it the White Sea, to distinguish it from the Black Sea; it must not, however, be confounded with the White Sea in the north of Russia. [See ARCHIPELAGO.]

ÆGI'NA, an island in the gulf of E'ghina, which retains its ancient name, with a very slight alteration. The 37° 47′ of latitude passes through the northern extremity of the island; its extent may be estimated by the scale attached to the accompanying plan, from Captain Copeland's recent survey.

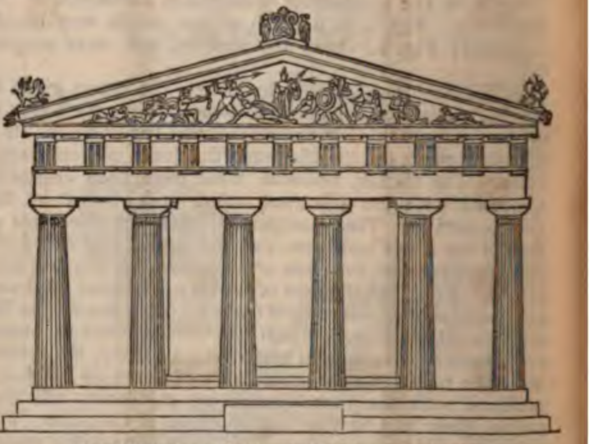
Strabo reckons Ægina to be 180 stadia in circumference, which, allowing nine stadia to a mile, will fall considerably short of the truth, if we reckon the numerous windings of the coast. The western part of the island is a plain, which, though stony, produces corn. A hill, called Mount St. Elias, or Oros, with its offsets, occupies the southern part of the island, and in the north-eastern we find a ridge, which, on one of its eminences, has the remains of the ancient temple of Jupiter Panhellenius, as it is commonly called. In the north-west part of the island there stand two columns, one of which is entire, marking the site of an ancient temple, with whose name we are unacquainted. To the south of these columns the site of the ancient town is distinctly shown by the remains of two artificial harbours, which have been formed, as was usual with the Greeks, by projecting moles, with a narrow entrance between them. The walls on the land side, which were about ten feet thick, can be traced through their whole extent. There were probably three principal gates, the central one leading to the eminence in the eastern part of the island, on which the remains of the ancient temple stand. This temple is situated amidst pine trees, on the summit of a mountain, and separated by a narrow valley from the hill on which the modern town of Eghina stands. The position of this edifice is striking. Placed in the middle of the gulf of Eghina, it offers a panoramic prospect of the whole bay. Athens and its Acropolis are eighteen miles distant N.N.E., and the towering Acropolis of Corinth thirty-seven miles to the N.W. (Leake's *Morea*, 3 vols. 8vo. 1830.)



On casting our eyes on this little island, we should almost doubt the stories of its ancient importance, if they were not as well authenticated as any part of remoter history. We know nothing worth mentioning here of its inhabitants before it was occupied by the Achæi (*Homer's Iliad*, ii. 562), and afterwards by some Dorians from Argos—a nation that spread over a large part of the Peloponnesus, and sent out colonies to Italy and Sicily, and formed in fact one of the chief component parts of that people known to general history under the name of the Greeks. Like some small republics of modern times, such as Genoa and Venice, Ægina owed its importance entirely to its naval superiority. It would however be difficult to see how so small an island could become a formidable naval power, if we did not know that its approach was rendered difficult by numerous rocks, and that at an early period it became a place of security for persons and their property. It is impossible that a place like Ægina could ever rise to importance except as an emporium or mart, which offered the advantages of security and a central position. Wealth being once introduced, would, by industry and perseverance, be increased, and a navy once established, would perpetuate itself by the profit derived from a carrying trade. As early as B.C. 563, in the reign of Amasis, before any town of European Greece had acquired great commercial wealth, we find that Ægina had a factory established in Lower Egypt for its merchants, which is exactly the same kind of thing that we have seen so often repeated in modern times, where the commercial towns of Europe have, by force or fraud, succeeded in establishing themselves in remote countries. In this century, according to the testimony of Aristotle, this little spot contained 470,000 slaves. This number is certainly extravagant; but we may consider it as indicating a very large population. Ægina was then one of the great centres of the Mediterranean commerce, and in all probability a considerable slave market.

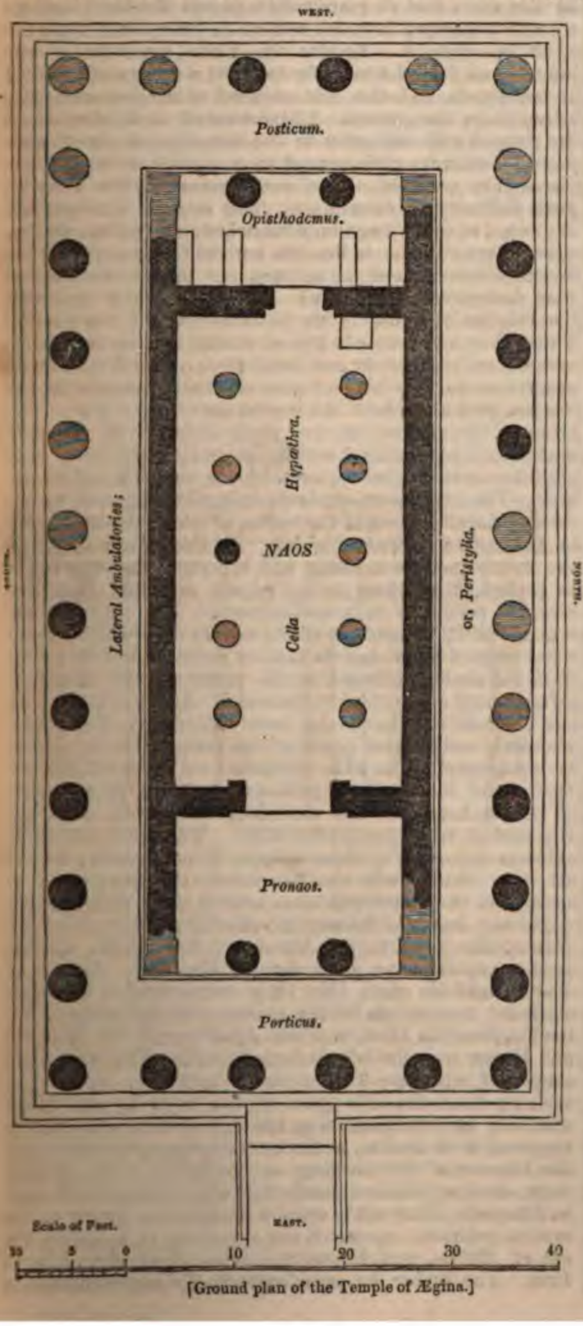
When Xerxes was on the banks of the Dardanelles in the year B.C. 480, with his enormous army, previous to crossing over into Europe, he saw, says Herodotus, the corn-fleet sailing by, carrying the harvests of the fertile regions on the Black Sea to the Peloponnesus and Ægina. Ægina had very early a silver coinage, and many of its coins still exist, though we are not aware what is the remotest epoch to which they belong. The most common type or figure on one side is the sea-tortoise. The story is that Pheidon, King of Argos, who also possessed Ægina, made a mint of silver in that island about B.C. 894; and it certainly was a tradition among the Greeks that, as early as that period, Ægina was the centre of an extensive commerce. [See an *Essay on Money*, Hatchard and Son. 1833.] When Xerxes invaded Greece B.C. 480, the people of Ægina took a brilliant part in the great sea-fight of Salamis. They sent thirty ships, besides those which guarded their own island, and were allowed to have acquitted themselves better than any other Greeks; which tended to wipe off the disgraceful imputation of previous treachery to the common cause, of which they were apparently not altogether guiltless. This event may be fixed as the latest period of their great prosperity, which had probably lasted for more than a century; and we must therefore assign the building of the great temple of Jupiter Panhellenius to some period in the sixth century before our æra. We may indeed almost with certainty fix it before B.C. 563, when the Æginetans built a temple to their great national god, Jupiter, in Egypt; which they would scarcely have done before they had erected one at home. After the Persian wars, the old jealousies of Athens and Ægina again broke out, and finally resulted in the more powerful state taking possession of the island, B.C. 430, and expelling the Æginetans. A remnant of them was restored by Lysander at the close of the Peloponnesian war, B.C. 404; but Ægina never after recovered its importance. Sulpicius, one of Cicero's friends, when consoling the illustrious orator for the loss of his daughter, enumerates Ægina among the instances of the vicissitudes of fortune, and as an example of fallen greatness. (Cicero's *Letters to various Persons*, iv. 5.)

Of late years the situation of Ægina, as a secure and central position, has made it the occasional meeting-place of the Senate of Greece, and residence of the governor; and several schools have been established here. The latest report that we have seen of their condition is not favourable. In the central school of Ægina, at the time of Professor Thiersch's late visit, nothing beyond Greek and a little mathematics were taught. (See *Journal of Education* No. 6.) The orphan asylum established here by the late President Capo d'Istrias, in the little town of Eghina, is described by the German professor as a failure. A previous account said there were 1500 pupils in this island, and an extensive Greek printing-house. But till Greece is in a more settled state, it is impossible to give anything like accurate information on the present condition of this island. Some accounts say that the island has 4000 inhabitants. It is known for the good almonds which it produces.



[Front Elevation of the Temple of Ægina, as restored.]

Ægina Temple. The temple of Jupiter Panhellenius, before referred to, or the Panhellenium of Ægina, as it is often called, was of the Greek Doric style or order, and of the arrangement which is technically termed hexastyle, peripteral, and hypæthral; that is, it had a portico of six columns at each end, and ranges of twelve columns along each side, the columns on the angles being counted both in flank and in front; and internally it was divided into what may be termed nave and aisles, by two ranges of columns, the space between which was uncovered. The cell or body of the temple was a regular parallelogram, inclosed by four walls: access was given to the interior by doors in the cross-walls, from inner porticoes formed by the longitudinal extension of the flank walls, the projecting shoulders of which are termed antæ, and between which two columns stand, thus forming what are distinguished as the pronaos and opisthodomus. The columns of the peristyle on the sides stand nearly as far from the walls as they do from each other; and on the fronts, the space intervening between the outer columns of the porticus and posticum (to use the technical terms by which the front and rear-front porticoes are respectively distinguished), and the inner ones and their antæ, of the pronaos and opisthodomus respectively, is somewhat more than a single intercolumniation. Thus, a kind of gallery was formed on the floor of the peristyle around the body of the temple, and this was raised by three deep steps from a nearly level platform called a *peribolus*, in the midst of which the temple stood; this was partly hewn out of the native rock, and partly constructed, and a low wall or parapet girded it on all sides. The temple fronted east and west, the east being the entrance front before which the peribolus extended itself more than 100 feet, while on the west it was not more than 50 feet wide. The extreme length of the temple in front, measured on the face of the lowest step of the regular stylobate, is 49 feet 10·2 inches, and in flank 100 feet 7·7 inches; and on the floor of the peristyle, that is, at the edge of the upper step on which the columns rest, the corresponding dimensions are, 45 feet 2·2 inches, and 96 feet. The columns of the peristyle are a very small fraction less than 3 feet 2·9 inches in diameter, and including their capital, they are 17 feet 9·4 inches in height; the entablature, without the crowning moulding of the pediments, is rather more than two diameters of a column in height, and the stylobate is 3 feet 7·7 inches high, or an eighth more than one diameter. The height of the tympana of the pediments to the soffit of the corona was, as nearly as it can be determined, one diameter and four-fifths, and that of the pediments to their apices, two diameters and two-sixths; making the whole height, from the floor of the peribolus to the summit of the pediments, 35 feet 8 inches, above which the acroterium rose nearly one diameter, or about three feet more. Both the tympana were highly enriched with sculptures, but it does not appear that there were any in the metopes of the outer entablature, or on any part of that of the inner ordinance of the pronaos and opisthodomus, as in the cases of the Parthenon and the temple of Theseus at Athens. It is true that Dr. Chandler discovered a sculptured fragment among the ruins, which, from some indications, he fancied to have belonged to one of the friezes; but later examinations make it probable that what he found belonged rather to the sculptures of the eastern pediment.



[Ground plan of the Temple of Ægina.]

The columns of the Panhellenium are within a small fraction of five diameters and a half in height, and they diminish, with an imperceptible entasis, in the length of the shaft, considerably more than one-fourth,—from 3 feet 2·9 inches to 2 feet 4·6 inches. In the peristyle, and in the pronaos and opisthodomus, the columns have twenty flutes, while those of the inner hypæthral ranges had but sixteen.

The annexed plan and elevation will convey a clear idea of the arrangement of the structure. The darker tint on the plan indicates the portions of the walls which remain, or whose places are not obliterated, and also the sites of the still remaining columns; the lighter tint shows the restorations. The ends of the walls forming the antæ are restored from analogy, and from displaced fragments discovered among the ruins;—the places of the deficient columns of the peristyle admit of no doubt, and those of the internal ranges are tolerably certain. Only *one* column remains of the internal ranges, but this determines the diameter and the distance from the walls of all the rest, and consequently the breadth of the hypæthral part or nave; but the number of columns in each range, and therefore their distances from each other, cannot be determined with certainty. However, the authority of the second volume of the Antiquities of Ionia would decide this, as its authors profess to have ascertained the position of five of the columns of these inner ranges, of which three were in continuous succession. The principal front of the temple would be sufficiently indicated by the greater depth of the inner portico or pronaos, even if the greater extent of the peribolus, and the superior merit of the sculptures at the east end, did not determine it. The meaning of the rectangular blocks of stone in the opisthodomus, and of that within the cella in the hypæthral range by the western door, is not obvious; nor does any reason offer itself for the place of that door being out of the middle, though its narrowness may mark its inferiority. Possibly, however, these irregularities and discrepancies may have been occasioned at some period during the middle ages, when, according to the belief of some writers, the old ruined temple was used as a church. A more graduated ascent than the regular gradus to the floor of the peristyle has been made, for more convenient access to the eastern portico; for it may be noticed that the steps of the stylobate are so deep as to make them inconvenient for use; probably, however, this too was the work of the later period before referred to. The elevation here given is applicable to either of the two fronts, though the sculptures indicated are those of the western pediment. The structure was built of the fine white limestone of the island, but through long exposure it has assumed a rich brown colour; the tiles used in covering were of the same material, but the sculptures appear to be of Parian marble. It may be remarked, too, that the surfaces of the tympana were painted of a light-blue colour to give the statues greater relief; and the statues themselves were also partially painted for the same purpose. The mouldings also appear to have been painted.

The style of the architecture of the Æginetan Panhellenium would of itself indicate an earlier date than that of the Athenian temples of the age of Pericles, but it would hardly lead us so far back as the early part of the sixth century before Christ; though it is not at all inconsistent with that period, which for another reason has been assumed for it. Some antiquaries have referred the execution of the sculptures which belonged to the Panhellenium to the latter part of the same century; but there is nothing in the reasoning by which they come to that conclusion that will not admit of these sculptures being referred to a remoter period. The great diminution of the columns; the great comparative depth of the capital, and its peculiar boldness of character; the greater comparative heights also of the stylobate and entablature, carry it back from the date of the Parthenon and the style of that period; while the height of the columns in proportion to their diameter, and the beauty of contour of the mouldings, and of other details, sufficiently remove it from the time of the heavy proportions and comparative rudeness of the older remains of Corinth. It differs too from all the Grecian temples of later date in the number of columns on its flanks.

It is unknown when the Panhellenium fell into ruins. Becoming neglected, and being exposed to the ravages of time and the shocks of earthquakes, one part after another must have fallen away until its dislocated joints offered to view portions of metal cramps, which would induce barbarian spoilers to rack it into pieces, till at length it became the ruin it now presents.

The subjoined sketch is a view of the temple in its present state. It is taken on the west front, looking eastward and northward; the walls are thrown down, though their site is not obliterated. A reference to the plan will show that the two columns in the foreground are the only remaining of the west portico, and that the two couples which appear within the external peristyle are those of the opisthodomus and pronaos. In the distance the view embraces the Saronic Gulph and the mountains of Attica.

[Ruins of the Temple of Ægina.]

This sketch, with the foregoing plan and elevation, were kindly furnished by Mr. W. Jenkins, Jun., architect, who made the original drawings and actual measurements of the remains on the spot, in October, 1820.

It is understood that Mr. Cockerell intends to publish a work on the Panhellenium, to which we must refer for more particular information than can be given here, and to the second volume of the *Antiquities of Ionia*, published at the expense of the Society of Dilettanti.

The sculptures which occupied the tympana of the pediments of the Panhelleniun were discovered in May, 1811, by a party of English and German travellers, among whom were Messrs. J. Foster, of Liverpool, and C. R. Cockerell, of London, who were pursuing their studies as architects. They were found buried under the ruins of the building and accumulations of rubbish, nearly as they had fallen from their places, especially those of the western front, the whole of which were recovered; but unfortunately not more than half of those of the eastern front could be determined. They are at present at Münich, having been allowed by the English government at that time, to fall into the hands of the present king of Bavaria (then the Prince Royal), who had them transported to the capital of Bavaria. Thorwaldsen was engaged to restore the statues. The Æginetan, added to the Athenian, and Phigaleian marbles which we possess in the British Museum, would have formed a complete specimen of Grecian sculpture, as applied to the decoration of temples. The Museum has not even a set of casts of the Ægina marbles, the only one in England accessible to the public being deposited in the Royal Institution at Liverpool. Even the Academy of the Fine Arts at Venice possesses a set of these casts, which the metropolis of the British empire is without.

ÆGINETAN STYLE OF ART. Several ancient writers, particularly Pliny and Pausanias, make frequent mention of Æginetan works of art; and in such a manner, as to show that the productions of the school of Ægina, to use a modern and well-understood phrase, were highly esteemed. Many names of Æginetan sculptors had thus come down to us as almost synonymous with excellence in their art, but the works of none of these could be recognized among those which had escaped the ravages of time and the desolation of barbarism; so that their merits and reputation rested on report alone. The discovery of the sculptures which adorned the tympana of the Panhellenium, the national temple of the Æginetans, has furnished us with undoubted specimens of Æginetan art, and of that period too, as some suppose, in which the most celebrated Æginetan sculptors flourished. The latter conclusion has, we think, been too hastily adopted. That the sculptures of the Panhellenium are of great beauty and merit, and are for many reasons highly interesting, will be admitted by all; but that they are of the class and date from which the school of Ægina derived its celebrity, may fairly be doubted.

These principally consist of perfect statues, or statues in the round as they are termed, somewhat smaller than life, of men armed with spears, swords, shields, and bows; the bowmen have quivers of arrows suspended from their waists; most of the figures are helmed or bonneted, some with greaves on the legs, and two or three with armour on the body, or close-fitting garments on the body and limbs; but for the most part they are naked, except the head, and all are either engaged in active combat or have fallen from the effect of wounds. Besides the male combatants, one helmed and draped female figure, with a spear and a shield in her hands, and the helmed head of another, evidently belonged to the groups. These were all so distributed on the ground with reference to the temple, and are of such peculiar attitudes with respect to one another, and to the places they occupied, that there appears to have been no great difficulty in determining their original arrangement in groups, after the fragments into which many of the figures were broken, were once brought together; especially as the frames which inclosed the pictures they formed, were otherwise determinable, and thus assisted materially in fixing the relative positions of the parts composing the groups. Thus, the perfect female figure, evidently a statue of Minerva, standing upright and in full face, occupied the central position under the highest part of the tympanum of the western pediment; and the combating warriors of that end arranged themselves on her right and left, in attitudes upright and advancing, kneeling, stooping and falling, until the inner acute angles terminated in the wounded and recumbent. The goddess stands in quiet dignity, prepared, nevertheless, for action, while the battle, of which she appears to be the umpire, rages around her. Of this picture or group, the arrangement is so fitting and complete, and the action so perfect, that there is no reason to think, that any essential portion of it is undiscovered. But unfortunately it is not so with the group of the eastern or principal front; a few only of these figures can be restored, and it is only from the analogy afforded by the western group, that their arrangement can be aptly determined. As far as the figures can be made out, the persons seem to be nearly, if not quite, identical, and another period of the same action appears to be represented. The helmed female head is that of Minerva again, and Mr. Cockerell restores her figure as in the act of raising her spear and extending her vest, as if to stop the contest, or to protect the fallen. The exact subject, or subjects intended by these groups, is not known; though all the critics who have offered opinions seem to agree that they represent some actions of the distinguished Æginetan family of heroes, the Æacidæ, or descendants of Æacus, the mythological founder of the nation. Colonel Leake's opinion, as given by Mr Cockerell, *Journal of Science and the Arts*, [No. 12, p. 334—Note] is that they represent two periods in the contest over the body of Patroclus, from the Iliad, in which Ajax (one of the Æacidæ) and Hector were the principal combatants. That something connected with the Trojan war is intended, seems very evident, from the Phrygian bonnet worn by one of the warriors; and the greaves on the legs of those who may be supposed to be Greeks, in the eastern group, especially, and the absence of this covering on the figures of the opposite party, seem to intimate clearly that some national difference is intended. Thiersch's opinion is, that the group on the eastern pediment represents the expedition of Telamon, the son of Æacus, and Hercules, against Laomedon, king of Troy. The archer he considers to be the representation of

Hercules. The other group, he thinks, may represent the death of Achilles, and the struggles of Ajax to save his body from the Trojans. (See Thiersch's *History of Greek Sculpture*, p. 249, note.)

There is nothing in the combination of sculpture and architecture more admirable than the manner in which the various actions and attitudes, in the more perfect group of the figures, have been adapted to the situations which they occupied; and this too, without the slightest appearance of constraint; they are all natural and graceful, and in perfect keeping with the design of the subject, and the character of the architecture. The energy of action, the grace of attitude, and the truth of proportion displayed in these works, are also admirable, and the expression of many of the figures is excellent. Nevertheless, there is a degree of dryness and rigidity observable in the bodies and limbs, which give the works an archaic character, whilst the countenances, the hair, and the draperies, clearly betoken their near approach to, if not absolute connexion with, the archaic period. The faces are entirely devoid of expression, the hair is formally laid in tiers with convoluted ends, and the draperies, though not devoid of grace, are heavy and monotonous: to use the words of the writer before referred to in the *Journal of Science and the Arts*, p. 340, describing the sculptures,—'A smile is seen on all the mouths, the cheeks are rather hollowed, the lips are thick, the nose is short but angular and prominent; the eyes are protruded, the forehead is flat and retiring, and the chin is remarkably long and rather pointed; the hair and drapery are arranged with the greatest precision.' Now these are peculiarities which could not have existed in the works of men whose names are mentioned with those of Phidias and his compeers and immediate successors; but they clearly mark a more remote period. Nevertheless the comparative fulness of form, and freedom of action of the bodies and limbs, equally indicate a date not far removed from excellence.

To the period when the archaic era was passing into that which succeeded it, and not to the perfection of the latter, we must then refer the Panhellenian sculptures; they are to the more advanced works of the Grecian schools what the works of Giotto, Cimabue, Ghirlandaio, Pietro Perugino, Giovanni Bellino, and others, are to the perfection of the art of painting under Michael Angelo, Raphael, and Titian. No one in describing the schools of Florence, Rome, and Venice, would make reference to the simple and beautiful, but still imperfect works of the earlier, but to the almost perfect productions of the latter masters; nor would Pliny and Pausanias refer to the archaic sculptures of the Panhellenium as the best specimens of the school of Ægina, but to such works as could be classed with the sculptures of the Parthenon, and many of the statues and busts which now adorn the galleries of the Vatican and the Capitol, or are distributed among the various European capitals.

ÆLFRIC, an eminent Saxon prelate. He is said to have been the son of an Earl of Kent, but at an early age he embraced a devotional life, and assumed the habit of the Benedictines, in the monastery of Abingdon. In 963, when Athelwold, the abbot of that house, became Bishop of Winchester, he took Ælfric along with him, and made him one of the priests of his cathedral. Here he remained till 987, when he removed to Cerne Abbey. Next year he was made Abbot of St. Alban's, and soon after was promoted to the Bishopric of Wilton. Finally, in 994, he was translated to the Archbishopric of Canterbury, over which see he presided with great ability till his death, on the 16th of November, 1005. Ælfric was one of the most learned ecclesiastics of that age, and distinguished himself, throughout his life, by a very praiseworthy zeal and activity in the diffusion of knowledge. The following are the principal works which have been attributed to him: 1. A Latin and Saxon Glossary, printed by Somner at Oxford, in 1659: 2. A Saxon translation of most of the historical books of the Old Testament, part of which was printed at Oxford, in 1698: 3. A charge to his clergy, in articles, commonly called his Canons, which was published, by Spelman, in the first volume of his *English Councils*: 4. Two volumes of Saxon Homilies, translated from the Latin fathers: and 5. A Saxon Grammar in Latin. There were, however, other Saxon ecclesiastics of his name, and it has been doubted if all the works enumerated were the productions of the Archbishop of Canterbury.

ÆGINHARD. [See Eginhard.]

ÆGYPT. [See Egypt.]

Æ'LIA CAPITOLI'NA, a name given to Jerusalem in the time of the Emperor Hadrian, who, finding the Jews very restless and unruly subjects, treated them as revolted people, and took possession of the capital, Jerusalem, from which the Jews were excluded under pain of death. Some Roman colonists were sent to Jerusalem, which received the name of Ælia Capitolina; Ælia, from Ælius, one of the names of Hadrian; and Capitolinus, from the temple of Jupiter Capitolinus, which was built on, or near, the Holy Mount.

The history of all this transaction is very obscure. It would seem, according to some opinions, that the attempt to establish a Roman colony in Jerusalem, and the introduction of heathen rites into the city, was the *cause* of the disturbances which led the emperor to treat Jerusalem as a conquered city. The founding of a new town, and the desecration of the holy places, led, probably, to the wars in which Barchochebas headed the Jews, and which were as destructive to the nation as their former resistance to Titus. The name of Ælia Capitolina continued in common use among the Greeks and Romans till the time of the Christian Emperors. [See Mannert, *Syrien*. p. 216. Schlosser, *Universal History*, vol. iii. part 1.] Several coins of Hadrian still exist, which refer to the colony established by the Emperor. They bear on one side the head of Hadrian, and on the other, a Jupiter seated between two figures, or an eagle perched upon a thunder-bolt, with an inscription, Col. Ael. Cap. (See Vallant's *Numismata*.)

ÆLIA'NUS, CLAU'DIUS, a Roman citizen and a native of Præneste (Palestrina), probably lived about the middle of the third century of the Christian era. Like Cicero, Atticus, and many other Romans, he made himself so completely master of the Greek language, as to write it with ease and correctness. There is extant a work of his in fourteen books, entitled, *Various or Miscellaneous History*, which is a compilation or collection of extracts made by the author in his extensive reading. This work may be considered as one of the earliest collections of Ana. The value of it does not consist in what the compiler has written, but in the passages of lost writers that he has been the means of preserving. An edition of this work was published at Paris in 1805, 8vo. with Heraclides of Pontus and Nicolaus of Damascus, by the learned Greek *Coray*. There is a French translation of Ælian's work, by M. B. T. Dacier, Paris, 1772, 8vo. with notes.

Another work of Ælian's, in sixteen books, also written in Greek, is entitled *On the Peculiarities of Animals*. Though the author cannot claim the merit of being a scientific naturalist, like Aristotle, he has preserved to us in this work a number of curious facts, which he had collected from such works as he had read. Each of the sixteen books is subdivided into small chapters or sections, like the Miscellaneous History. Some critics are of opinion that the two works belong to different authors. [Schoell, vol. ii. *Greek Lit.*] J. G. Schneider published an edition of the work on animals in 1784; but the latest edition of the Greek text is by F. Jacobs, *Jena*. We are not aware that there is any English translation of this work. There are also twenty Greek letters extant attributed to a person of the name of Ælian.

ÆLIA'NUS, another person of this name, wrote a book on Tactics, which he dedicated to the Emperor Hadrian. There are several editions and translations of this work. A German translation, by A. H. Baumgärtner, appeared in his complete collection of the Greek writers on military tactics, *Frankenthal* and *Mannheim*, 1779, 4to. There is a French translation by B. de Bussy, Paris, 1757, 2 vols. 12mo. [*Schoell.*]

ÆMI'LII, the name of a patrician gens or clan in ancient Rome, who pretended to derive their origin from Mamercus, the son of Pythagoras. Of the different families included in this gens, the most distinguished were the Pauli, or Paulli, the Lepidi, and the Scauri. [For the two latter, see Lepidus and Scaurus.] Among the Paulli, the most worthy of notice was Lucius Æmilius Paullus, the son of the consul bearing the same name, who fell in the battle near Cannæ (B. C. 216), after using his utmost efforts to check the rashness of his colleague. Young Æmilius was a mere boy at the death of his father, yet by his personal merits, and the powerful influence of his friends, he eventually attained to the highest honours in his country. His sister Æmilia was married to Publius Cornelius Scipio, the conqueror of Hannibal, who was consul for the second time, B. C. 194; and this very year Æmilius, though he had held no public office, was appointed one of three commissioners to conduct a colony to Croton, in the south of Italy, a city with which he might claim some connexion on the ground of his descent from the Pythagoreans. Two years after, at the age of about thirty-six, he was elected a curule ædile in preference, if we may believe Plutarch, to twelve candidates of such merit that every one of them became afterwards consuls. His ædileship was distinguished by many improvements in the city and neighbourhood of Rome. The following year (191 B.C.) he held the office of prætor, and, in that capacity, was governor of the south-western part of the Spanish peninsula, with a considerable force under his command. The appointment was renewed the following year, but with enlarged powers, for he now bore the title of proconsul, and was accompanied by double the usual number of lictors. In an engagement, however, with the Lusitani, 6000 of his men were cut to pieces, and the rest only saved behind the works of the camp. But this disgrace was retrieved in the third year of his government by a signal defeat of the enemy, in which 18,000 of their men were left upon the field. For this success a public thanksgiving was voted by the senate in honour of Æmilius. Soon after, he returned to Rome, and found that he had been appointed, in his absence, one of the ten commissioners for regulating affairs in that part of western Asia which had lately been wrested by the two Scipios from Antiochus the Great. Æmilius was a member also of the college of augurs from an early age, but we do not find any means of fixing the period of his election. As a candidate for the consulship he met with repeated repulses, and only attained that honour in 182 B.C., nine years after holding the office of prætor. During this and the following year he commanded an army in Liguria, and succeeded in the complete reduction of a powerful people called the Ingauni (who have left their name in the maritime town of Albenga, formerly Albium Ingaunum). A public thanksgiving of three days was immediately voted, and, on his return to Rome, he had the honour of a triumph. For the next ten years we lose sight of Æmilius, and at the end of this period he is only mentioned as being selected by the inhabitants of Farther Spain to protect their interests at Rome, an honour which at once proved and added to his influence. It was at this period (171) that the last Macedonian war commenced, and though the Romans could scarcely have anticipated a struggle from Perseus, who inherited from his father only the shattered remains of the great Macedonian monarchy, yet three consuls, in three successive years, were more than baffled by his arms. In 168 a second consulship, and with it the command against Perseus, was entrusted to Æmilius. He was now at least sixty years of age, but he was supported by two sons and two sons-in-law, who possessed both vigour and ability. By Papiria, a lady belonging to one of the first families in Rome, he had two sons and three daughters. Of the sons, the elder had been adopted into the house of the Fabii by the celebrated opponent of Hannibal, and, consequently, bore the name of Quintus Fabius Maximus, with the addition of Æmilianus, to mark his original connexion with the house of the Æmilii. The younger, only seventeen years of age at this period, had been adopted by his own cousin, the son of Scipio Africanus, and was now called by the same name as his grandfather by adoption, viz., P. Cornelius Scipio, with the addition of Æmilianus, as in his brother's case. The careless reader of Roman history often confounds these two persons, and the more so, as the younger also eventually acquired the same title of Africanus. By the marriage of his daughters again, Æmilius was father-in-law to Marcus Porcius Cato, son of the censor, and to Ælius Tubero. These four young men accompanied Æmilius to the war in Macedonia, and all contributed in a marked manner to his success. Perseus was strongly posted in the range of Olympus to defend the passes from Perrhæbia into Macedonia, but he allowed himself to be outmanœuvred. Æmilius made good his passage through the mountains, and the two armies were soon in view of each other near Pydna. On the evening before the battle, an officer in the Roman army, named Sulpicius, obtained the consul's permission to address the troops upon a point which was of no little importance in those ages. An eclipse of the moon, it was known to Sulpicius, would occur that night, and he thought it prudent to prepare the soldiers for it. When the eventful moment arrived, the soldiers went out indeed to assist the moon in her labours with the usual clamour of their kettles and pans, nor omitted to offer her the light of their torches; but the scene was one of amusement rather than fear. In the Macedonian camp, on the other hand, superstition produced the usual effect of horror and alarm; and on the following day the result of the battle corresponded to the feelings of the night. In a single hour the hopes of Perseus were destroyed for ever. The monarch fled with scarcely a companion, and on the third day reached Amphipolis. Thence he proceeded to Samothrace, where he soon after fell into the hands of the conqueror. The date of the battle of Pydna has been fixed by the eclipse to the 22d of June. Livy, indeed, assigns it to a day in the early part of September; but it is not impossible that the difference may be owing to some irregularity in the Roman calendar, which, prior to the Julian correction, must often have differed widely from the present distribution of the year. The Romans were careful in recording the day of every important battle. After reducing Macedonia to the form of a Roman province, Æmilius proceeded on his return to Epirus. Here, under the order of the senate, he treacherously surprised seventy towns, and delivered up to his army 150,000 of the inhabitants as slaves, and all their property as plunder. On his arrival in Rome, however, he found in this army, with whom he was far from popular, the chief opponents of his claim to a triumph. This honour he at last obtained, and Perseus with his young children, some of them too young to be sensible of their situation, were paraded for three successive days through the streets of Rome. But the triumphant general had a severe lesson from affliction in the midst of his honour. Of two sons by a second wife, (he had long divorced Papiria,) one aged twelve died five days before the triumph, the other, aged fourteen, a few days after; so that he had now no son to hand down his name to posterity. Æmilius lived eight years after his victory over Perseus, in which period we need only mention his censorship, B.C. 164. At his death, 160 B.C., his two sons, who had been adopted into other families, Fabius and Scipio, honoured his memory in the Roman fashion by the exhibition of funeral games; and the Adelphi of Terence, the last comedy the poet wrote, was first presented to the Roman public on this occasion. The fact is attested by the inscription still prefixed to the play. Æmilius found in his grateful friend Polybius one willing and able to commemorate, perhaps to exaggerate, his virtues. Few Romans have received so favourable a character from history. (See Polybius, Livy, Plutarch.)

ÆNE'AS, a Trojan prince of the royal blood, son of Anchises and Venus. According to Homer he commanded the Dardanians; and his name occurs frequently in the Iliad, but not in the first rank of heroes. He owes his celebrity to those stories which make him the reputed founder of the Roman empire in Italy, and to his being the hero of Virgil's poem. According to the Latin poets, on the night when Troy was taken, or, as others say, before its capture, Æneas quitted the city, bearing on his shoulders his aged father, and the images of his household gods; accompanied by his wife Creusa, who perished by the way, and his son Iulus, also called Ascanius. The older authors do not speak of the multitude of followers and number of ships with which Virgil has adorned his narrative. According to them he quitted the Trojan shores in a single ship to seek his fortune in the unknown regions of the west. After many wanderings he reached the coast of Latium with one hundred followers, and was favourably received by Latinus, king of the country, who assigned a small tract of ground as a settlement for the Trojans. But war soon broke out between the strangers and the natives. Turnus, prince of the Rutuli, joined Latinus to expel the foreigners; but the allied princes were defeated, and Latinus was slain in the first battle. Lavinia, his daughter, became the bride of the victor, and the citadel of Laurentum fell into his hands. Æneas now built the city of Lavinium, which was hardly completed, when Turnus again appeared in arms, assisted by Mezentius, king of Cære. Another battle ensued, in which Turnus fell; but the Latins were defeated, and Æneas was drowned, or at least disappeared, in the river Numicius. He was afterwards adored as Jupiter Indiges: a temple was raised to him on the bank of the river; and the Latins, and in later ages, the consuls of Rome, offered yearly sacrifices to him under that name. Iulus, his son by Creusa, succeeded to the throne, and founded a city, celebrated in the history of Latium, called Alba Longa. He was succeeded by Sylvius, son of Æneas and Lavinia, from whom a long line of Latin kings descended. Iulus, however, left progeny, though their claims seem to have been set aside in consequence of the maternal title of Sylvius:

since the Julian family, and among them the imperial house of Cæsar, boasted their descent from the former. Such is a sketch of the chief traditions about this reputed Trojan prince and his settlement in Italy. [See Niebuhr's *Roman History*, vol. i., p. 176. Hare and Thirlwall's translation.]

The only allusion in Homer to the history of Æneas after the Trojan war is, a prediction that he and his children shall reign for centuries over the Trojans: nothing is said of the place of their settlement. Some have supposed that he remained in the Troad, and that the story of his emigrating to Italy is entirely destitute of foundation.

Æ'NEID. The most celebrated epic poem of antiquity, after the Iliad and Odyssey. It was written by Virgil in the time of Augustus Cæsar; and relates the wanderings of Æneas after the siege of Troy; his arrival in Italy, and his adventures previous to his marriage with Lavinia, with his final establishment in Latium. The poem, however, does not carry its hero so far as this, but closes with a single combat between Æneas and Turnus, and the death of the latter. In some respects Virgil has deviated from the legend related in the article Æneas. He has multiplied the Trojan ships and increased the number of the Trojans; he has carried his hero to Carthage, though we do not know whether Carthage existed at the supposed date of Æneas' wanderings; he has made the death of Turnus precede the marriage of Æneas and the foundation of Lavinium, and has allowed Latinus to survive, instead of making his daughter wed the author of her father's death. The poem consists of twelve books, of which the six first are occupied in relating the wanderings of Æneas, and seem to be modelled on the Odyssey; the six last contain his descent into Italy, and the war which ensued between the Trojans and the natives, and seem to be modelled on the Iliad. In the minute details of ornament as well as in the general notions of his work, Virgil has borrowed largely from Homer. This poem was written later than his other works, the Eclogues and Georgics. It was commenced about the year A.U.C. 724, or B.C. 30; and the author continued to labour on it till his death, in B.C. 20; at which time he was so little satisfied with the state of his production that, it is said, he gave earnest injunctions on his death-bed that it should be burnt, as too imperfect to advance his fame. The order was not fulfilled, at the desire of Augustus, who intrusted the publication to two learned friends of the author, Tucca and Varus. Many lines are left imperfect; some suppose this to be one proof that the finishing hand of the master was never applied; but we doubt whether it is, and think it possible that they were purposely left so. It called forth the enthusiastic admiration of his contemporaries. Propertius wrote—

> Yield, Roman poets; lords of Greece, give way;
> The Iliad soon shall own a greater lay;

and some writers, even in modern times, have expressed the same opinion. The merits of these poets will be better discussed under their respective names. It is enough to say that, compared with the Iliad, the Æneid is wanting in originality and power: it is evidently the laboured performance of a learned man, possessed of an elegant mind, who has availed himself freely of the labours of those who have preceded him. Virgil is characterized by Niebuhr as possessing 'a genius barren for creating, great as was his talent for embellishing.' The characters of the Æneid are deficient in the individuality and freshness which mark the descriptions of those who have mingled in scenes, and been familiar with characters such as they portray. The brave Gyas, and the brave Cloanthus are hardly distinguishable, except by name: Achates, the friend of Æneas, is a mere shadow, always attending on his chief; and, indeed, with the exception of Dido, no character is well defined. Æneas himself, though the hero of the poem, neither excites any strong interest nor leaves any powerful impression. In this respect Virgil is immeasurably inferior to Homer. The former, from his own imagination, or from the writings of older authors, had to create characters and describe manners such as he had never seen; the latter was familiar with men and actions such as he described them, or at least he embodied the vivid traditions of an early and poetical age. The strength of Virgil lay in the pathetic rather than in the sublime; and many passages of the Æneid, which admitted of the former quality, are exquisitely beautiful.

The Æneid has been frequently translated into most European languages. In our own, we may notice one peculiarly interesting to the literary antiquary; a translation, by Gawin Douglas, bishop of Dunkeld, of the whole Æneid into the old Scottish dialect, about 1512; and said by Mr. Warton to be the first translation of a classic into the language of Britain. The Earl of Surrey translated the second and fourth books, printed in 1577. There are complete translations by Ogilby, Pitt, &c., but the energetic version of Dryden has nearly superseded all others.

ÆNI'GMA, a Greek term for what is commonly called a riddle. It is the description of a thing by certain of its qualities selected and disposed, with the object of hiding what the thing is, and of occasioning its discovery to come as a surprise.

An ænigma differs from a definition or other direct statement, not in being false, but only in being obscure and misleading. The one is an instance of the application of language to make known our thoughts, and the other of its application to the purpose of concealing them: but the words of a good ænigma, when properly understood, are as true as those of a good definition. It is also an indispensable quality of the latter, as well as of the former, that it shall be intelligible, in its whole import, only in one sense.

The object of a direct statement is to convey information; that of an ænigma is to exercise the ingenuity. The former, in its simplest and most legitimate form, has only to be *received* by the mind; the latter demands to be *solved.* An ænigma, therefore, may be regarded as one of the complex or ornamented modes of composition, that is to say, one of those which do not merely appeal to the apprehension, but excite and gratify other intellectual faculties.

In very ancient times, accordingly, the ænigma was a common and favourite medium for the conveyance even of truths of the highest importance. Formal composition in the earliest state of society, that it might be the better distinguished from ordinary speech, naturally affected an elaborately artificial character; and the ænigma or riddle presented itself among other devices for that end. It had, besides, the peculiar recommendation of giving an air of mystery to the sentiment which it involved, and so making it seem to be something still more remote than it might really be from common experience and speculation. The term ænigma, indeed, was probably used originally to describe any short composition, such as an apologue, or fable, or other portable sample of wisdom or entertainment. Ænigma is something *dark* and *obscure*, and the corresponding verb (*αἰνίττεσθαι*) always means to speak *ænigmatically*, according to our meaning of the word, or to speak with a certain degree of mystery and obscurity.

In the progress of civilization and literature, it came to be felt that obscurity and difficulty were qualities, which, whatever pleasure they might convey to those who tried to master them, were inconsistent with all the higher and more appropriate objects of speaking and writing. Whether the purpose be simply to communicate information, or whether it be to appeal also to the imagination and the passions, a style is good exactly in proportion as it is expressive, that is to say, as it conveys directly and completely the thoughts of the writer or speaker. The ænigma, therefore, the very end and nature of which is the reverse of this, instead of being an ornament, must be regarded as one of the worst faults of style. Whatever *approaches* towards the ænigmatical, is, for the same reason, a fault in writing—whatever figure, for example, is introduced in poetry or rhetoric more in order to surprise the reader by its ingenuity than for any other purpose. Amongst those writers who have vitiated their works by what may be called an ænigmatic turn of phraseology, Young is an instance, in his *Night Thoughts.*

ÆO'LIAN HARP, a musical instrument, the sounds of which are drawn from it by a current of air acting on the strings; hence it is named after *Æolus*, to whom in the heathen mythology is given the command of the winds.

Rather before the middle of the last century, the Æolian Harp was brought forward in London as a newly-invented instrument; and Dr. Anderson, in a note to Thomson's *Ode on Æolus's Harp*, ascribes the invention of it to Mr. Oswald, (the composer of Scottish songs, we presume,) adding, 'its properties are fully described in *The Castle of Indolence.*' However, it is possible that an instrument of the kind was very anciently known, for the Talmudists say that the *Kinnor*, or harp of David, sounded of itself when the north wind blew on it. But the merit of the invention in the form it now takes, is due to Athanasius Kircher, who, in his *Musurgia Universalis*, (lib. ix. 352,) thus describes it: 'As the instrument is new, so also is it pleasant and easy to construct, and is heard in my museum to the admiration of every one. It is silent as long as the window in which it is placed remains closed, but when this is opened, a sudden harmonious sound breaks forth which astonishes the hearers, for they neither perceive whence it proceeds, nor what kind of instrument is before them, for the sounds do not resemble those of a stringed or of a pneumatic instrument, but partake of both. The instrument is made of pine wood, is five palms long, (fifteen inches,) two broad, and one deep: it may contain fifteen or more strings, all equal, and of catgut. The method of tuning it is not, as in other instruments, by 3ds, 4ths, 5ths, &c., but all the strings are to be in unison or in octaves, and it is wonderful that such different harmony should be produced from strings thus tuned.'

A modern writer gives the following more detailed directions for the construction of the Æolian harp, and such as we know, from experiment, are better calculated to produce the intended effects. Let a box be made of as thin deal as possible, of a length exactly answering to the window in which it is intended to be placed, four or five inches in depth, and five or six in width. Glue on it, at the extremities of the top, two pieces of wainscot, about half an inch high and a quarter of an inch thick, to serve as bridges for the strings; and withinside, at each end, glue two pieces of beech about an inch square, and of length equal to the width of the box, which is to hold the pegs. Into one of these bridges fix as many pegs, such as are used in a pianoforte, though not so large, as there are to be strings; and into the other, fasten as many small brass pins, to which attach one end of the strings. Then string the instrument with small catgut, or *first* fiddle-strings, fixing one end of them, and twisting the other round the opposite peg. These strings, which should not be drawn tight, must be tuned in unison. To procure a proper passage for the wind, a thin board, supported by four pegs, is placed over the strings, at about three inches distance from the sounding-board. The instrument must be exposed to the wind at a window partly open; and to increase the force of the current of air, either the door of the room, or an opposite window, should be opened. When the wind blows, the strings begin to sound in unison; but as the force of the current increases, the sound changes into a pleasing admixture of all the notes of the diatonic scale, ascending and descending, and these often unite in the most delightful harmonic combinations, producing

"A certain music, never known before,"

says Thomson, in his *Castle of Indolence*, who goes on describing the instrument as one

"From which, with airy fingers light,
Beyond each mortal touch the most refined,
The God of Winds *draws* sounds of deep delight;
Whence, with just cause, the harp of Æolus it hight.
Ah me! what hand can touch the string so fine?
Who up the lofty diapason roll
Such sweet, such sad, such solemn airs divine,
Then let them down into the soul?

* * * * *

Wild-warbling nature all, above the reach of art!"

The learned Matthew Young, B.D., formerly of Trinity College, Dublin, has entered deeply into the nature of the Æolian harp, in his *Enquiry into the principal Phænomena of Sounds*, &c., and as his work is rare, we shall here avail ourselves of his remarks on this subject:—

'The phænomena of the Æolian lyre may be accounted for on principles analogous to those by which the phænomena of sympathetic tones are explained.' [See Sympathetic Sounds.] 'To remove all uncertainty in the order of the notes in the lyre, I took off all the strings but one, and on placing the instrument in a due position, was surprised to hear a great variety of notes, and frequently such as were not produced by any aliquot part of the strings: often, too, I heard a chord of two or three notes from this single string. From observing these phænomena, they appeared to me so very complex and extraordinary, that I despaired of being able to account for them on the principle of aliquot parts. However, on a more minute enquiry, they all appear to flow from it naturally and with ease.

'But let us consider what will be the effect of a current of air rushing against a stretched elastic fibre. The particles which strike against the middle point of the string will move the whole string from its rectilineal position; and as no blast continues exactly of the same strength for any considerable time, although it be able to remove the string from its rectilineal position, yet, unless it be too rapid and violent, it will not be able to keep it bent: the fibre will, therefore, by its elasticity, return to its former position; and, by its increased velocity, pass it on to the other side, and so continue to vibrate and excite pulses in the air, which will produce the tone of the entire string. But if the current of air be too strong and rapid, when the string is bent from the rectilineal position, it will not be able to recover it, but will continue bent and bellying like the cordage of a ship in a brisk gale. However, though the whole string cannot perform its vibrations, the subordinate aliquot parts may, which will be of different lengths in different cases, according to the rapidity of the blast. Thus when the velocity of the current of air increases, so as to prevent the vibration of the whole string, those particles which strike against the middle points of the halves of the string, agitate those halves as in the case of sympathetic and secondary tones; and as these halves vibrate in half the time of the whole string, though the blast may be too rapid to admit of the vibration of the whole, yet it can have no more effect in preventing the motion of the halves, than it would have on the whole string were its tension quadruple; for the times of vibration in strings of different lengths, and agreeing in other circumstances, are directly as the lengths; and in strings differing in tensions, and agreeing in other circumstances, inversely as the square roots of the tensions. and, therefore, their vibrations may become strong enough to excite such pulses as will affect the drum of the ear; and the like may be said of other aliquot divisions of the string. In the same manner as standing corn is bent by a blast of wind, and if the wind be sufficiently rapid, it will have repeated its blast before the stem of corn can recover its perpendicular position, and therefore will keep it bent. But if it decays in rapidity or strength, the stem of corn will have time to perform a vibration before it is again impelled; and thus it will appear to wave backwards and forwards by the impulse of the wind. Those particles which strike against such points of the string as are not in the middle of the aliquot parts, will interrupt and counteract each other's vibrations, as in the case of sympathetic and secondary tones, and, therefore, will not produce a sensible effect.' With regard to those notes which cannot be produced by any exact submultiple of the string, but which, notwithstanding, are sometimes heard on the Æolian harp, Mr. Young observed that they were always transitory, gradually rising or falling to such notes, above or below them, as would be produced by exact aliquot parts of the whole string.

Mr. Young follows the principles here laid down, by a series of experiments, which are of a very satisfactory nature, but for these we must refer the reader to the work itself.

ÆO'LIAN ISLANDS, the ancient name of the eleven small islands north of Sicily, now generally called the Lipari Islands.

ÆO'LIAN MODE, in ancient music, one of the five principal modes of the Greeks, which derived its name, not from the Æolian isles, but from Æolia, a country of Asia Minor. What this mode was, it is now difficult, if not impossible, to determine. Writers of all times and kinds differ most essentially from each other on the subject. Rousseau says it was grave: the Abbé Feytou contradicts him. Sir F. Stiles tells us that this mode was the same as our E flat: Dr. Burney makes it F minor; and Rousseau says F, meaning, of course, F major. See Mode.

ÆO'LIANS, the name of one of those various peoples, whom we are accustomed to class under the general appellation of Greeks. We trace the name of Æolians to Thessaly, their primitive abode, as far as we know, where they appear to have been closely related to the Phthiotic Achæans of the same country. What was the nature of their relationship to the Dorians who dwelt successively in Phthia, Olympus, Pindus, Dryopis and the Peloponnesus, we cannot determine; but undoubtedly their languages were very closely allied. The Achæi of the Peloponnesus (the Achæi of Homer) were also kinsmen, and, in fact, part of the Æolians; and the great emigration, commonly called the Æolian, was an emigration of Achæan people. It seems probable that the emigration from the Peloponnesus commenced before the Dorian invasion, or return of the Heraclidæ, as it is often called, which caused so great a revolution in the Peninsula; but it cannot be doubted that this event contributed still further to the Achæan or Æolian emigration under Penthilus the son of Orestes, and others of Agamemnon's descendants. This great revolution in the Peloponnesus, caused by an invasion of hardy mountaineers and conquerors from Northern Greece, took place, as the best-informed Greek historians believed, eighty years after the war of Troy, or B.C. 1104; and apparently caused a retrogression in the condition of southern Greece, and drove out a more civilized race. Strabo says that the Æolian settlements in Asia were four generations prior to those called the Ionian. The Æolian colonies on the Asiatic main land were widely spread, extending at least from Cyzicus along the shores of the Hellespont and the Ægean to the river Caicus, and even the Hermus. Many positions in the interior were also occupied by them, as well as the fine island of Lesbos, with Tenedos, and others of smaller importance. Homer mentions all these parts as possessed by a different people; which would be a proof, if any were wanting, that the race of new settlers came after his time. There were twelve cities or states included in the older settlements in that tract of Asia Minor on the Ægean, which was known in Greek geography by the name of Æolis, and formed a part of the subsequent larger division of Mysia. Smyrna, one of them, which early fell into the hands of the Ionians, the neighbours of the Æolians, still exists nearly on the old spot, with exactly the same name, thus adding one to the many instances of the durable impression made by Greek colonists wherever they settled.

But besides these twelve states, to which we have alluded, (most of which were near the coast,) there were many Æolian towns founded by the new comers along the Hellespont, the range of the Ida mountains, and on the coast of Thrace.

The name Æolic is often applied to a branch or dialect of the Greek language; but as we do not possess any entire work written in this dialect, we cannot satisfactorily compare it with the Attic, or that variety of the Greek language in which the tragedies of Æschylus, Sophocles, and Euripides, the histories of Thucydides and Xenophon, and the orations of Æschines and Demosthenes are written. There is no doubt, however, that it approached nearest to the Doric dialect of the Greek language, such as it was spoken in most parts of the Peloponnesus after the great Dorian invasion already mentioned.

ÆOLIPYLE, ÆOLIPILE, *Aeoli pila, the ball of Æolus*, an instrument made use of formerly in experimenting, consisting of a hollow ball, with a small orifice in which a tube might be screwed. It served to boil water in, for the purpose of creating steam. This instrument is mentioned by Des Cartes, in his treatise on *Meteors*, chap. iv., as used in his time. It is now entirely out of use, unless we choose to consider the boiler of a steam-engine as an æolipile. This is by no means the first instance in which a philosophical toy has been made of use to the arts.

ÆRA, a point of time from which *subsequent* years are counted, and in some instances *preceding* years, as in the Christian æra. The origin of the word *æra* is very doubtful.

All nations who have any history to record have fixed their æra at some remote period, in order to embrace in their annals as large an extent of time as practicable. The creation of the world would most naturally present itself to those who might have any means of ascertaining the time of its occurrence, and the Bible would be the source from whence the information might be obtained. But, unfortunately for chronology, the Bible is not sufficiently explicit on this subject; and, although the Jews and some Christian nations do date from the Creation, their computations of the period at which this event took place differ to the extent of nearly two thousand years. Those whom this uncertainty has deterred, or who have had no knowledge of the Scriptures, have contented themselves with more recent periods. The ancient Romans adopted the epoch of their first supposed political existence, and the Greeks that of the first celebration or revival of the Olympic Games, which were with them an important national festival. Many nations have assumed some event closely connected with their religious faith: thus, the early Christians of the East dated from the persecution under the Emperor Diocletian, and those of Europe and America, at the present day, from the birth of Christ. All the followers of Mohammed have adopted, as an æra, the retreat of their prophet from Mecca to Medina, which they call the Hegira.

Many of these æras are arbitrarily and incorrectly fixed, and even our own is erroneous by four years. But an error at the commencement will not invalidate the dates of events recorded subsequently, as any æra once assumed will be sufficient to show the succession of time, however incorrectly assigned to the period whose name it bears.

With one or two exceptions, all nations have reckoned time in accordance with the course of the seasons; they have always begun their year at the same season, sometimes perhaps a little earlier, and sometimes later, but invariably keeping near the original commencement.

Here follows a list of the æras which have been or are most in use among the civilized nations of the world, with the year of the Christian æra in which they began:—

1. The year of the world according to the reckoning of Constantinople, which was used in Russia until the beginning of the eighteenth century, and is still employed by the Greek church - - - - - - - - - - - - - - B.C. 5509
2. The year of the world as reckoned at Antioch, now used in the Abyssinian church - - - B.C. 5492

[The church of Alexandria originally assumed the year B.C. 5502 as the year of the Creation, but in the year 285 A.D. they discarded ten years, and thus acceded to the computation of Antioch.]

3. The year of the world used by the Jews - - B.C. 3761
4. The Caliyuga, employed by the learned throughout India, may be called an æra of the Creation, being considered by the Hindoos as the commencement of the present state of the world, or 'Iron Age' - - - - - - - - B.C. 3102
5. The Olympiads; the æra of the victory of Corœbus at the Olympic games, used chiefly by the Greek historians after the age of Alexander - - - - - - - - - - - - - B.C. 776

[N.B. An Olympiad is a period of four years.]

6. The building of Rome: this is generally called the Varronian æra - - - - - - - - - - - B.C. 753
7. The Catonian æra of the building of Rome is* B.C. 752
8. The æra of Vicramaditya, in common use throughout India - - - - - - - - - - - B.C. 57
9. The Spanish æra, from the conquest of Spain by Augustus, was employed in Spain, Portugal, Africa, and the South of France. In some provinces this æra was in use until the middle of the fifteenth century - - - - - - B.C. 38
10. The æra of Salivahana, in common use through the southern and western states of India - - A.D. 78
11. The æra of Martyrs, or of Diocletian, so called from the persecution of the Christians in the reign of that emperor, was much used by the early Christians, and is still employed in the churches of the East - - - - - - - - - - A.D. 284
12. The Hegira, used by all Mohammedans, dates from the flight of Mohammed to Medina - - A.D. 622
13. The Christian æra dates from the birth of Christ; the year in which he was (erroneously) supposed to be born is called 1 B.C., the following year 1 A.D. Many authors call the year of our Lord's birth 0, and consequently make the dates of all preceding events one year less than by the common practice.

The following rules will serve to show the year of the Christian æra corresponding with that of any given æra:—

1. When the commencement of the given æra precedes the birth of Christ, subtract from the given year the number affixed to the æra in the above list, and the remainder will be the year of Christ in which the given year began.

If the given year be less than the affixed number, subtract it from that number, adding one; the result will be the date before Christ.

Examples.—Required the Christian date answering to the year of Rome 1754.

From 1754
Deduct 753

The year 1001 A.D. corresponds with the year 1754 A.U.C.

Required the year B.C. answering to 707 A.U.C.

From 753
Deduct 707

46
Add 1

The year 47 B.C. coincides with 707 A.U.C.

The reason is this: A.U.C. 707 means that an event took place *in* that year; and therefore 753—706 or 47 years B.C. remain, and as all the years B.C. *before* B.C. 47 have expired, the event must take place *in* the year B.C. 47.

---

* See Ideler's *Chronology*, p. 334.

Required the year of Christ in which the year of the Jews 5591 began.

From 5591
Deduct 3761

Answer A.D. 1830

2. When the commencement of the given æra follows the birth of Christ, add to the given year the number affixed to the æra in the list, less one. The sum will be the year of Christ in which the given year began.

Example.—Required the Christian year in which 1031 of Martyrs began.

To the given year 1031
Add the number in the list less one 283

The year A.D. 1314 answers to the year 1031.

All the above dates may be reduced to the Christian æra by the same formula, except that of the Hegira, as the Mohammedans allow only 354 days to the year. Mohammedan reckoning is thus at variance with the course of the seasons; their year now begins in May, changes to March in 1840, and to December in 1850, and thus gains at the rate of a little more than three years in a century. It will, therefore, be necessary to prepare any given date from the Hegira by subtracting three years for every hundred, before reducing it to the Christian æra.

Required the year of the Hegira 1245
Subtract 3 years for every hundred 37

1208
Add the number in the list less one 621

1829

The year of the Hegira 1245 began in the year 1829 A.D.

3. The computation by Olympiads may be thus explained: for instance, Ol. lx.3 means that an event took place *in* the *third* year of the *sixtieth* Olympiad, and consequently *in* the year that followed the expiration of 59 Olympiads (or 59 periods of 4 years each), and 2 more years belonging to the sixtieth Olympiad; or after the expiration of 238 years, and therefore *in* the year B.C. 538.

AERIAL PERSPECTIVE, a term in painting, implies, in its simple definition, the receding of objects into distance, as seen through the medium of air. In its general application, however, it is to be understood in a more enlarged sense. Linear perspective may be considered the material guide of the artist, originating in, and governed by, mathematical science; but aërial perspective is, in whatever relates to *effect*, amenable to no positive law or established rule, and depends for its application on the perceptions and capacity of the artist. Although entering into every variety of subject, in graphic representation, it is in open scenery that aërial perspective is exhibited in its proper sphere. To feel this, it will only be necessary to recollect in how different an aspect the same scenery may present itself under different modifications of the atmosphere. A prospect, which at noon day, or in a clear and bleak morning, appears tame and uninteresting, shall assume an ideal character, and start into combinations of beauty, if seen at sunrise or at sunset, or under any temperature of the sky favourable to the development of picturesque effect.

It is, of course, in those schools of painting, wherein the study of external nature, especially of landscape, has been most cultivated, that we are to look for the finest examples of aërial perspective. The Roman and Florentine masters, whose object, almost exclusively, was human form and character, seem to have felt or understood but little of it. The Dutch and Flemish painters exhibit high excellence in this particular, as is shown in the works of Rubens, Rembrandt, Teniers, Ostade, Cuyp, Ruysdael, Wouvermans, Vanderveldt, &c. France, however, has the glory of having produced the artist Claude Lorraine, who, in this great quality of art, has borne off the palm from all competitors. He rarely painted any other effects than those of the rising or the setting sun, well knowing their picturesque superiority; but whatever be his subject, an ancient port, or ruins, or temples, the great and presiding charm of Claude is his consummate skill in aërial perspective. If there be any artist who, in the treatment of aërial perspective, can compete with Claude, that competitor, perhaps, is Cuyp. His pictures are direct portraits of the scene before him,—the willowy lake, the marsh, the meadow, the drowsy shepherd, and the ruminating cow. But, in spite of the simplicity of these materials, and an horizon, in general, perfectly flat, he communicates to his works an effect of air and distance, and consequently of reality, which must rank them among the most astonishing efforts of art. To these may be added a third, the English Wilson, whose breadth and brilliancy of style, and whose conspicuous mastery in the practice of aërial perspective, give him a right to rank with Claude and with Cuyp in this quality.

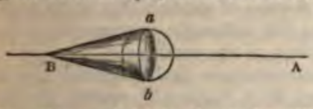
AERO-DYNAMICS, signifies the science which treats of the motion of the air, or of the mechanical effects of air put in motion. In its widest sense, it might be taken to include the effects of the motion of any gaseous substance or vapour; and even the properties of steam might be considered as a part of the science. We shall, however, confine ourselves to the explanation of the few general principles which can be relied upon; the applications of which will be found in the articles WIND, WINDMILL, AIR-GUN, SAIL, BELLOWS, RESISTANCE, GUNNERY, &c.

The air is an elastic fluid,—that is, any portion of it can be confined in a smaller, or expanded into a larger space, than it would naturally occupy. In either case a force or pressure is to be overcome; the air itself resists compression; and the pressure of the superincumbent air is to be overcome before any expansion can take place. The natural state of the air to which we have alluded, varies, as indicated by the rise or fall of the BAROMETER, which, at the level of the sea, is usually between twenty-eight and thirty-one inches in height, that is, the flat bottom of any vessel is pressed by a weight, arising from the air, such as would be obtained by filling it with mercury to a height of from twenty-eight to thirty-one inches. This pressure is estimated at from fourteen to fifteen pounds avoirdupois on every square inch. [See AIR.]

As soon as we begin to move, we feel, more or less, the resistance of the air. At an ordinary rate of motion, this is not very perceptible; but the jockey, who rides at the rate of from thirty to forty miles an hour, feels it sensibly, and is obliged to wear a cap which may *cut* the wind, as the bow of a ship *cuts* the water, or otherwise it would be blown off his head, though, in the common sense of the word, there might be no *wind* stirring at the time. Whenever we attempt to put any matter in motion, we feel what is denominated pressure or resistance, which is the greater the greater the quantity of matter we attempt to move, and the velocity we attempt to communicate to it. Thus, two violent pressures, of equal force, applied for an instant to weights of ten and twenty pounds, will make the weight of ten pounds move twice as fast as that of twenty; or, if we would have the two move equally fast, we must apply twice as much pressure to the twenty pounds weight as we do to that of ten pounds. If we now conceive a number of equal balls placed in a line, along which we move the hand uniformly, so as to set them all in motion one after the other, we might at first imagine that if we move the hand at the rate of two feet in a second, and afterwards at the rate of four feet in a second, that we exert twice as much force, and encounter twice as much resistance, in the second case, as in the first. Because, we say, we move each ball in the second case twice as fast as in the first. But there is another consideration: we not only move each ball twice as fast, but we meet with twice as many balls in a second, so that not only the velocity we communicate in a second is doubled, but also the quantity of matter to which we communicate that velocity is doubled, or, there is four times as much resistance to twice the velocity, as there was to the single velocity. Similarly, at three times the rate of motion, we meet with three times as much matter, and communicate to each portion three times the velocity: whence we meet with three times three, or nine times the quantity of resistance. If we transfer this reasoning to the case of a body moving through the air, we should infer, that the resistance is, to speak mathematically, as the SQUARE of the velocity: that is, if the velocity be suddenly made ten times as great, the resistance is made ten times ten, or a hundred times as great. And this, which was the first theory proposed on the subject, is sufficiently near the truth for practical purposes, when the velocities are not very great; for example, up to eight or nine hundred feet in a second.

But one circumstance has been neglected. The succes sive particles of air which the moving body strikes, instead of being moved out of the way completely, are forced upon those in front, so that there is a condensation of air before the moving body; which condensation, as we have seen in ACOUSTICS, is propagated onwards at the rate of about 1125 feet in a second. In the meanwhile, the space through which the body moves, or has moved, is, or has been, entirely cleared of air; and though the air is forced with great rapidity into the vacant space, yet this is not done instantaneously, as we shall presently see from experiment. Therefore though, when at rest, the atmospheric pressures before and behind the body counterbalance each other, yet when in motion, there is an increase of the pressure before the body, and a diminution of that behind it; both which circumstances increase the resistance.

From theory, tolerably well confirmed by experiment, it appears, that if air of the ordinary pressure be allowed to rush into a *vacuum*, or space entirely devoid of air, it will be driven in at first with a velocity of about 1340 feet per second; or, to avoid an appearance of accuracy of which we are not actually in possession, we may say between 1300 and 1400 feet per second. If now, instead of rushing into a vacuum, the air which comes through the orifice meets with other air of a less density, say one-fourth of its own density, the velocity above-mentioned will be diminished in the proportion of 1 to the square root of $1-\frac{1}{4}$, or of 1 to $\sqrt{\frac{3}{4}}$, or of 2 to $\sqrt{3}$, or of 100 to 87, very nearly. By a similar process any other case may be computed. Let us now imagine a ball, *a b*, made to move forward in the direction B A, with an initial velocity less than 1000 feet per second. Let B be the last point of its track at which the air has completely recovered its former state. The air in the cone B*a b* will not have entirely recovered its state, but will all be more or less rarefied; so that in addition to the loss of motion arising from communication to the particles of air, there is a part of the atmospheric pressure on the front of A B, uncounterbalanced from behind. The condensation in front of A B is propagated, as in ACOUSTICS, quicker than the ball moves; so that the air in front continues, if not entirely, at least very nearly, in its natural state. We cannot say that the cases of air rushing through an orifice into a vacuum, and filling up the space left by a ball, have any decided similarity; nor can we say the contrary, owing to the very imperfect state of the mathematical analysis of this part of the subject. We may, however, conjecture that when the ball moves with a velocity greater than that of sound, thereby condensing the air before it, and leaving a perfect vacuum behind it, or nearly so, the resistance will be much greater than the theory in the first part of this article would lead us to expect. And this proves to be the case at even less velocities than the one just specified; for though up to 1000 feet per second, or thereabouts, the resistance increases very nearly with the square of the velocity, yet from that point it increases in a much quicker ratio; so that to a ball moving at the rate of 1700 feet per second, it is three times as great as we should obtain from our first hypothesis. The resistance to an iron ball of twelve pounds weight, moving at the rate of twenty-five feet per second, is equivalent to a pressure of half an ounce avoirdupois; if we increase twenty-five feet per second to 1700 feet per second, or multiply the first sixty-eight times, the square of which is 68×68 or 4624, we might, from the first part of this article, expect a resistance of 4624 half ounces, or 144½ pounds; instead of which, it is found to be 433½ pounds; about three times the preceding, as we said. At a velocity of 1600 feet per second, the resistance was found to be more than twice that given by the theory. Without entering further into details, for which the reader may consult the article GUNNERY, to which they particularly apply—and also without considering the effect which the different forms of bodies have upon the RESISTANCE, (to which refer)—we give some of the conclusions to which Dr. Hutton was led by a long and careful repetition of the experiments of Mr. Robins, his celebrated predecessor in the same track. For the method of conducting these experiments, see WHIRLING MACHINE, BALLISTIC PENDULUM.



1. The resistance is nearly in the same proportion as the surface exposed, but a little greater than this proportion on the larger surface. That is, if we take two bodies of the same figure and material, (two iron spheres for example,) the surface of the second being twice that of the first, the resistance to the larger sphere is a little more than twice that of the smaller, the velocities being the same in both.

2. The round ends and sharp ends of solids suffer less resistance than the flat ends of the same. Thus, the sharp end or vertex of a cone is less resisted than the flat end or base.

3. Two solids, having the parts presented to, or which push the air, the same, are not equally resisted unless the hinder parts are also the same.

Though we have hitherto considered the resistance offered to a body moving against still air, and the pressure which is necessary to maintain it at a given velocity, yet the problem is exactly the same, if we suppose the body to remain still, and the air, or as we now call it, the wind, to move against it with the same velocity. Suppose the body to move 100 feet in a second, and that the spectator is carried along without his knowledge at the same rate. He will, therefore, always be in the same place with respect to the body, and will at the same time imagine that the air or wind is coming towards him at the rate of 100 feet per second. The force which, when he imagined the body moving, he called the pressure necessary to maintain its velocity, he will now say is the pressure necessary to steady it against the wind.

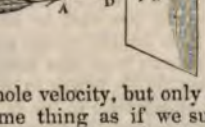
If we suppose both the wind and the body in motion, the resistance is variously modified, according to the direction of the motions of the two. If the wind and the body move in the same direction, with the same velocity, there is no resistance, for no air is displaced by the body. If the wind move 50 feet per second, and the body 100 feet, the pressure on the body is the same as if it were at rest, with a *contrary* wind of 50 feet per second blowing on it. If the wind and the body move in contrary directions, with velocities of 100 feet, the resistance is that of a wind of 200 feet per second; and so on. If the spectator move with the body unknowingly, the magnitude and direction which he will assign to the wind is that which will produce such a pressure on the body *at rest*, as it really sustains when in motion. [See APPARENT MOTION.]

The following well-known table, first given by Mr. Smeaton in the *Philosophical Transactions* for 1759, and confirmed by the experiments of Dr. Hutton, shows, in pounds avoirdupois, the pressure which different winds will exert upon a square foot of surface exposed directly against them. The first column is a rough representation of the second.

Velocity of Wind.		Force on one square foot in pounds avoirdupois.	Character of the Wind.
Miles per Hour.	Feet per second.		
1	1·47	·005	Hardly perceptible.
2	2·93	·020	Just perceptible.
3	4·40	·044	
4	5·87	·079	Gentle, pleasant wind.
5	7.33	·123	
10	14·67	·492	Pleasant, brisk gale.
15	22·00	1·107	
20	29·34	1·968	Very brisk.
25	36·67	3·075	
30	44·01	4·429	High winds.
35	51·34	6·027	
40	58·68	7·873	Very high.
45	66·01	9·963	
50	73·35	12·300	Storm or tempest.
60	88·02	17·715	Great storm.
80	117·36	31·490	Hurricane.
100	146·70	49·200	Destructive hurricane.

For the method of obtaining these results see ANEMOMETER.

Let us suppose the square foot of surface placed obliquely, so as to make an angle A B C, with the direction A B of the wind. Let D B represent the velocity of the wind per second. Then, if D E be drawn perpendicular to B C (see COMPOSITION OF VELOCITIES) the wind which strikes the plane at B does not strike it directly with its whole velocity, but only with the velocity D E; it being the same thing as if we supposed the wind to be carried direct against the plane with the velocity D E, and at the same time shifted on the surface from C towards B with the velocity E B. This last will only make different particles of air strike the point B, but not with different forces. This line D E is in



trigonometry proportional to the *sine* of the angle D B E. Again, if we draw E F perpendicular to D B, the whole of the velocity D E is not in the direction of the wind, A B, but only the part of it D F; the other component, F E, being employed in moving the plane in a direction perpendicular to that of the wind. This line, D F, which represents the *effective* velocity of the wind in the direction A B, is, as the square of the sine of the angle A C B. The line, D F, is a third proportional to D B and D E, so that if we suppose the wind to move at the rate of 100 feet in a second, and the plane to be so inclined that it strikes the plane directly with only eighty feet of velocity, we have, for the real effective velocity 100 : 80 :: 80 : 64; or we must consider this plane as resisting a wind of only 64 feet of velocity. This theory is liable to the objections of the former one, as it does not allow for any condensation, but supposes the particles to disappear after they have struck the plane. Nevertheless, it is found in practice to answer well enough when the plane is not very oblique to the wind. For the mathematician, we may state that the following empirical formula is found from Smeaton's experiments to be much nearer the truth, which, as he will see, is nearly equivalent to the square of the sine of the angle of inclination, when the latter is nearly a right angle. Let the angle of inclination of the surface be θ, and the velocity of the wind V, then the effective velocity is

$$V \sin \theta^{1\cdot842 \cos\theta} \text{ nearly.}$$

For further information, we should recommend the treatise on Pneumatics, written for the *Encyclopædia Metropolitana*, by Professor Barlow, in which the experiments referred to in this article will be found clearly detailed: and also to the articles RESISTANCE, WIND, ANEMOMETER, in Dr. Hutton's *Mathematical Dictionary*.

AEROLITES, called also METEORIC STONES, are bodies which have fallen on the earth from the atmosphere, and are named from ἀήρ (*aer*), atmosphere, and λίθος (*lithos*), a stone. We possess historical records from very remote antiquity, and numerous writers in all ages have mentioned instances, of the remarkable phenomenon of stony bodies having been seen to fall from the sky; yet, till within the last thirty years, all such accounts were treated as tales of the ignorant and superstitious. The history of aërolites affords a most useful lesson how cautious we ought to be not to reject too hastily the narratives either of early authors or of living witnesses, however extraordinary they may be, solely on the ground that they are inconsistent with our experience of the laws of nature. When the official notice from the local authorities, of the shower of stones at L'Aigle in Normandy, in 1803, was received at Paris, it afforded a subject of merriment to the wits of that day; and the newspapers expressed their compassion for the good people of L'Aigle, who were governed by a mayor so silly as to give credit to such nonsense as that stones had fallen from the clouds. The first man of science who directed attention to the subject of aërolites was Chladni, a German philosopher, who, in a tract published at Riga and Leipzig, in 1794, upon the mass of native iron found by Pallas in Siberia, maintained the credibility of the traditions of that and other stony bodies having fallen from the air. His sagacious inductions, although they failed at the time to make any great impression, prepared philosophers for a more willing reception of the evidence as to two instances of the same extraordinary event, which were shortly afterwards brought under their notice. In 1796, a stone was exhibited in London, weighing fifty-six pounds, which was said to have fallen in Yorkshire, in December of the preceding year; but, although the fact was attested by several credible witnesses, the possibility of such an occurrence was still doubted. It was remarked, however, by Sir Joseph Banks, that there was a great resemblance between the Yorkshire stone and one in his possession, sent to him from Italy, with an account of its having fallen from the clouds, along with many others of a similar nature, near Sienna, in July, 1794. In the year 1799, Sir Joseph Banks received a circumstantial account, accompanied by specimens, of a fall of stones from the atmosphere, which was said to have taken place near Benares, in the East Indies, in the preceding December; and as these specimens were also nearly identical with the Yorkshire stone, incredulity began to give way. It was not, however, until the appearance of the celebrated paper of Howard, in the *Philosophical Transactions* for 1802, giving an account of his analysis of the Benares stone, that men of science declared their belief in the phenomenon, supported, as the evidence then was, by the researches and opinion of so cautious and accurate an inquirer; and the fall of stones at L'Aigle, above alluded to, which took place in the following year, at the time the memoir of Howard was in the hands of the public, removed all doubt. The Institute of France deputed the celebrated Biot to examine, on the spot, the whole circumstances attending this remarkable event; and the result of his labours will be found in his report, in the seventh volume of the *Mémoires de l'Institut*. He satisfied himself of the authenticity of the facts which had been narrated; and the specimens he collected on the ground, being analysed by Vauquelin and Thenard, yielded the same result as the analysis of the Benares stone by Howard. Thus was the ingenious induction of Chladni, in 1794, confirmed beyond dispute; and Cuvier, in his Report, in 1809, of the Progress of Science during the preceding ten years, states 'that the phenomenon of stones fallen from the atmosphere, known both in antiquity and during the middle ages, had only been established as truths in physical science, during that period, by the conjectures of Chladni, the analyses of Howard, Vauquelin, and Laugier, and the researches of Biot.' Chladni was entitled to far more honourable mention than to have his sound inductions designated as conjectures. By this series of observation and experiment, not only was the truth of the recent occurrences established, but the instances recorded by the writers of past times, which had been rejected as the delusions of a credulous and ignorant age, received so high a degree of probability, as to entitle them to be classed among the authentic documents of past events in the physical history of the earth.

An account of the circumstances that attended the fall of stones at Benares and at L'Aigle will convey the best idea of the phenomenon, not only as it occurred in these two cases, but in most other instances of which a circumstantial description has been preserved. They are always accompanied by a meteor, which at night appears like a burning fiery ball, surrounded by a brilliant vapour, and with a tail like a comet; in the day, on account of the strong light of the sun, and the smoke and vapour evolved, the meteor looks more like a small cloud of different colours, and of a singular form, which, after a powerful explosion, seems to burst and scatter its contents.

At a short distance from Benares, on the 19th of December, 1798, about eight o'clock in the evening, in the form of a large ball of fire; it was accompanied by a loud noise, resembling that of thunder, which was immediately followed by the sound of the fall of heavy bodies. On examining the ground, it was observed to have been newly torn up in many places, and in these stones were found of a peculiar appearance, most of which had buried themselves to the depth of six inches. At the time the meteor appeared, the sky was perfectly serene, not the smallest vestige of a cloud had been seen since the 11th of the month, nor were any observed for many days after. It was seen in the western part of the hemisphere, and was only a short time visible. The light from it was so great, as to cast strong shadows from the bars of a window upon a dark carpet, and it appeared as luminous as the brightest moonlight. Many of the stones were collected, and some of them weighed two pounds each.

On the 26th of April, 1803, at one o'clock in the afternoon, the sky being clear, with the exception of a few light clouds, a ball of fire was observed in Normandy, in many places far distant from each other—namely, Caen, Falaise, Alençon, Verneuil, and Pont Audemer, which moved rapidly from south-east to north-west; and about the same time, in the district of L'Aigle, loud explosions were heard, which lasted from five to six minutes, resembling the sound of cannon and musketry, and were followed by a long-continued noise, like that of many drums. The meteor from which the noise proceeded appeared not so much like a ball of fire, but rather like a small rectangular cloud, which, during the phenomenon, seemed not to move; but the vapour of which it consisted, was sent out, after each explosion, in all directions. It seemed to be about half a league north-west from L'Aigle, and must have been at a very considerable elevation, at it appeared to the inhabitants of two villages more than a league distant from each other, to be immediately over their heads at the same instant. Throughout the whole district over which the cloud hung, there was heard a hissing noise, like that of a stone from a sling, and a vast number of stones fell to the ground. The space on which they fell formed an ellipse of two leagues and a half long by one broad, the larger diameter being from south-east to north-west, the direction in which the meteor moved: the largest stones were found at the south-east end of the ellipse, and the smallest at the opposite extremity. Above two thousand were collected, and they varied in weight from two drams to seventeen pounds and a half.

Aërolites, when taken up soon after their fall, are extremely hot. They are generally angular, of prismatic and pyramidal forms, the angles being rounded; their broken irregular surface is coated with a fused black crust, like varnish, seldom exceeding a quarter of a line in thickness. When broken, they differ a little in appearance; but they are, for the most part, composed of a collection of small spherical bodies, of a grey colour, imbedded in a gritty substance, and often interspersed with yellow spots. One of the most remarkable circumstances is the great similarity of composition of all the meteoric *stones*, on whatever part of the earth they have fallen. Iron is found in all, and in a considerable proportion, partly in a malleable state, partly in that of an oxide, and always in combination with a greater or less proportion of the rare metal called nickel: the earths silica and magnesia and sulphur constitute the other chief ingredients; but the earths alumina and lime, the metals manganese, chrome and cobalt, together with carbon, soda, and water, have also been found in minute and variable quantities, but not in the same specimens. The variations discovered by analysis are never, however, sufficient to destroy that affinity of external character by which they are instantly recognized. No new substance, nothing with which we were not already acquainted, has ever been discovered in their composition. But, although all the constituent elements are found in different mineral substances, no combination of them, similar to that in meteoric stones, has ever been met with, either among the stratified rocks of any period of formation, or among the unstratified rocks, or among the products of any volcano, extinct or in activity. Their specific gravity is about 3.50, but varies according to the proportion of iron which they contain. They are sometimes very friable, sometimes very hard; and some that are friable when they first fall, become hard afterwards. In size they vary from two drams weight to three hundred pounds. One of the stones which fell at L'Aigle yielded by the analysis of Thenard,—

Silica	46 per cent
Magnesia . . .	10
Iron	45
Nickel	2
Sulphur . . .	5

and Laugier afterwards discovered the presence of chrome in it. Frequently small detached portions of malleable iron are disseminated through the mass, and the black crust acts powerfully on the magnet.

The appearance of these bodies is not periodical, nor connected with any particular state of the atmosphere, nor of the weather; and they have fallen in all climates, on every part of the earth, at all seasons, in the night and in the day.

Chladni has compiled a very copious catalogue of all recorded instances, from the earliest times: of which twenty-seven are previous to the Christian era; thirty-five from the beginning of the first to the end of the fourteenth century; eighty-nine from the beginning of the fifteenth to the date of the fall at L'Aigle at the beginning of the present century; and it appears from Chladni's list, and Van Hoff's continuation, that during the last thirty years, since the attention of scientific men has been directed to the subject, above sixty different cases have been recorded. Numerous as these may appear, they can form but a small proportion of the whole amount, when we compare the small extent of surface occupied by those capable of keeping a record of such events, with the wide expanse of the ocean, the vast uninhabited deserts, mountains, and forests, and the countries possessed by savage nations. Many of those which occur in the night must also escape observation even in civilized countries.

Among the more remarkable instances to be met with in ancient authors, the following may be mentioned. Livy states that, in the reign of Tullus Hostilius (about 654 years B. C.), a shower of stones fell on the Alban Mount, not far distant from Rome. Plutarch, in the Life of Lysander, describes a stone that fell at Ægos Potami, in the Hellespont, near the modern Gallipoli, about 405 B. C., which is also mentioned by the elder Pliny (Book II.), who says that it was to be seen in his time, that is, five hundred years afterwards, and that it was as large as a waggon, of a burnt colour, and its fall was accompanied by a meteor. It is also recorded in the Parian Chronicle. The mother of the gods was worshipped at Pessinus, in Galatia, under the form of a stone, which was said to have fallen from heaven; and that stone, in consequence of a treaty with Attalus, king of Pergamus, was solemnly brought to Rome by Publius Scipio Nasica, about 204 years B. C., and placed in the Temple of Cybele. The sun was worshipped at Emesa, in Syria, under the form of a large, conical, *black* stone, which, as the people about the temple reported, fell upon the earth. It was afterwards brought with great pomp to Rome by Elagabalus, who had been high-priest of the temple; and the description of it, given by Herodian, (Book V.) accords with the appearance of a meteoric stone.

One of the cases of more modern date, most circumstantially described, is that of the stone which fell at Ensisheim, in Alsace, in 1492. The Emperor Maximilian being there at the time, ordered an account of the event to be drawn up. It weighed 270 pounds; and was afterwards suspended by a chain in the church at Ensisheim for three centuries. During the French revolution, it was carried off to Colmar, and many pieces were broken from it. One of these is in the museum at the *Jardin des Plantes*, near Paris; it is identical in composition with other meteoric stones, and contains native or malleable iron. What remained of the precious relic has since been restored to the good people of Ensisheim, and it now stands near the great altar in their church.

Besides aërolites properly so called, masses of malleable iron, often of vast size, have been found in situations, which, together with their composition, leave no doubt as to their being of meteoric origin. An immense mass, seen by Pallas in Siberia, which forms the subject of Chladni's tract in 1794 above alluded to, was found quite insulated, at a great elevation on a mountain of slate near the river Jenesei, removed from everything that could excite suspicion of its being a production of art, and totally different from any ore of iron seen either before or since that time. The tradition was, that it had fallen from heaven, and, as such, was held in veneration by the Tartars; but it was removed in 1749 to the neighbouring town of Krasnojarsk by the inspector of the iron mines there. The mass, which weighed about 1400 lbs., was of an irregular form, not solid, but cellular like a sponge, the cells containing small granular bodies of a glassy nature, afterwards found to be the simple mineral olivine, so common in basalt. The iron was tough and malleable, and, according to the analysis of Howard, yielded 17 per cent. of nickel, but Klaproth and John found a much smaller proportion of nickel, and Laugier found by another analysis silica, magnesia, sulphur, and chrome. The disagreement of such skilful operators shows that the mass was not uniform in its composition. Another vast mass of meteoric iron was found in South America, in the jurisdiction of Santiago del Estero, about 500 miles north-west from Buenos Ayres, and is described in a memoir in the Spanish language, printed in the Philosophical Transactions for 1788, by Don Rubin de Celis, who was sent by the governor of the province to examine it. It lay in a vast plain of above a hundred leagues in extent, half sunk in the ground, and the size was such as, estimating it by the specific gravity of iron, would give a weight of more than thirteen tons. According to the analysis of Proust and of Howard, it contains 90 per cent. of iron, and 10 of nickel. Specimens of this mass, which were sent to the Royal Society by Don Rubin de Celis, are in the collection of the British Museum. A mass of meteoric iron at the Cape of Good Hope, mentioned by Barrow in his Travels in Africa, as an artificial production, is described by Van Marum in the Haarlem Transactions, a large portion of it having been sent to the public museum there by the governor of the colony. The mass, when found, was equal to about 177 lbs., but much had been carried away. The specific gravity is 7.604. Tennant found it to contain 1.10 per cent. of nickel, and a trace of carbon, and Stromeyer detected cobalt in it, which last metal has also been found by Dr. Turner in some meteoric iron from Buenos Ayres. Another mass was found in Brazil, about fifty leagues from Bahia, the weight of which was estimated at 14,000 lbs.; a fragment of this, analysed by Dr. Wollaston, yielded 4 per cent. of nickel. Many other instances of similar masses of iron might be mentioned, which are evidently of meteoric origin; but the only instance on record of iron having been actually seen to fall from the atmosphere, is that which took place at Agram, in Croatia, in 1751. On the 26th of May, about six o'clock in the evening, the sky being quite clear, there was seen a ball of fire, which shot along with a hollow noise from W. to E., and after a loud explosion, accompanied by a great smoke, two masses of iron fell from it, in the form of chains welded together.

Aërolites and meteoric iron are not the only products of meteors which have fallen upon the earth after explosion. Numerous instances are mentioned of black and red dust, which has covered great tracts of land; and it is remarkable that such dust has generally been found to contain small hard angular grains resembling augite. There have also been cases of the fall of a soft gelatinous matter of a red colour like coagulated blood, which have given rise to the stories of the sky having rained blood. Such appearances have not unfrequently accompanied the fall of stones. On the 15th November, 1755, rain of a red colour fell around Ulm and the Lake of Constance, and on the same day in Russia and Sweden. The red water was of an acid taste, probably from the presence of sulphuric acid; and the precipitate, which was flaky like snow, when dried, was attracted by the magnet. In the night of the 5th March, 1803, a red dust, in some places accompanied by rain, fell in different parts of Italy. In Apulia, there was first a very high wind with much noise, and then a reddish black cloud appeared coming from the S.E., from which there fell a yellowish-red rain, and afterwards a quantity of red dust. It continued the whole of the following day and part of the succeeding; the dust was examined, and was not found to be volcanic. Fabroni, in the Annales de Chimie, tom. lxxxiii, says, that near Arezzo, in March, 1813, the ground being then covered with snow, there was a shower of fresh snow of a red colour, which continued for many hours, accompanied the whole time with a sound like that of the violent dashing of waves at a distance; the greatest fall was accompanied with two or three explosions like thunder. The red snow being melted, a precipitate was obtained of a nankeen colour, which yielded silica, lime, alumina, iron, and manganese.

The origin of this remarkable class of natural phenomena is involved in great obscurity, and many different theories have been proposed to account for them. By some they have been supposed to be bodies ejected from distant volcanos belonging to our earth,—a conjecture which is refuted by every circumstance connected with them. No substance in the least resembling aërolites has ever been found in or near any volcano; they fall from a height to which no volcano can be supposed to have projected them, far less to have given them the horizontal direction in which meteors invariably move for a considerable part of their course. Another hypothesis is, that meteoric bodies are formed in the atmosphere, which is equally untenable; for, in the first place, there is no ground for supposing, from any discoveries yet made in chemistry, that the elements of which they are composed exist in the atmosphere; and even if they did, the enormity of the volume of the atmosphere, attenuated as it is at the great height from which the meteors fall, which would be required to produce a solid mass of iron of thirteen tons weight, places the conjecture beyond all credibility. But even granting so extravagant a proposition, and supposing the mass to be formed, what force could exist in the atmosphere to project it with the velocity with which meteors move, which has been calculated to be often greater than that of the earth in its orbit? A third hypothesis is, that they are bodies thrown out by the volcanos which are known to exist in the moon, with such force as to bring them within the sphere of the earth's attraction. This hypothesis was so far entertained by Laplace, that he calculated the degree of lunar volcanic force that would be necessary for this purpose. He calculated that a body projected from the moon with a velocity of 7771 feet in the first second would reach our earth in about two days and a-half; but Olbers and other astronomers are of opinion that the velocity of the meteors, which has been estimated in some cases to be at first equal to some miles in a second, is too great to admit of the possibility of their having come from the moon. The theory which is most consistent with all known facts and laws of nature is that proposed by Chladni, viz., that the meteors are bodies moving in space, either accumulations of matter as originally created, or fragments separated from a larger mass of a similar nature. This opinion has also been advanced by Sir Humphrey Davy, at the conclusion of one of his papers in the Philosophical Transactions for 1817, giving an account of his researches on flame. 'The luminous appearances of shooting stars and meteors cannot,' he says, 'be owing to any inflammation of elastic fluids, but must depend upon the ignition of solid bodies. Dr. Halley calculated the height of a meteor at ninety miles, and the great American meteor which threw down showers of stones was estimated at seventeen miles high. The velocity of motion of these bodies must, in all cases, be immensely great, and the heat produced by the compression of the most rarefied air from the velocity of motion must be probably sufficient to ignite the mass; and all the phenomena may be explained, if *falling stars* be supposed to be small solid bodies moving round the earth in very excentric orbits, which become ignited only when they pass with immense velocity through the upper region of the atmosphere, and if the *meteoric bodies* which throw down stones with explosions be supposed to be similar bodies which contain either combustible or elastic matter.'

Those who wish to investigate this curious subject will find it most ably and copiously treated in Chladni's work, '*Ueber Feuer-Meteore, und über die mit denselben herabgefallenen Massen*,' Vienna, 1819. He continued his researches to the time of his death, and published them in *Gilbert's Annalen der Physik*, since which time the subject has been taken up by his friend Von Hoff, in Poggendorf's continuation of Gilbert. The '*Lithologie Atmosphêrique*' of Izarn may also be consulted; and there is a good compilation by Bigot de Morogues, entitled '*Mèmoire historique et physique sur les Chûtes des Pierres*,' Orleans, 1812.

AËRONAUTICS. From two Greek words, signifying *sailing in air*. [See BALLOON.]

AËROSTATICS, AËROSTATION, derived from two Greek words signifying, *standing in air*, is the science which teaches the equilibrium of bodies supported in air, gas, or vapour. For every essential point not explained in HYDROSTATICS, refer to BAROMETER, and BALLOON.

Æ'SCHINES, commonly called the *Orator*, to distinguish him from another of the same name, was born at Athens B.C. 393. At this period of Athenian history, orator and statesman may be considered as almost synonymous terms, for, without some superiority in the art of speaking, it was impossible to attain any great eminence in political life. In all communities of a democratic character, the power of public speaking, which too often includes the power of deceiving large numbers, has been to the adventurer one of the surest passports to political eminence, and to a people one of the causes of national misfortune. sophistry and words have often had the victory over honesty and wisdom. These remarks are suggested by reflecting on the history of Æschines and his rival Demosthenes, both of whom elevated themselves by their oratorical talents to the most prominent stations in the Athenian democracy; and though they have, by mutual recrimination, cast grievous imputations on the character of each other neither of them has been so fortunate as to free himself from the well-grounded suspicion of political, if not private, dishonesty.

The name of Æschines' father was Atrometus. According to the account of his enemies, he had been a slave, and had obtained his freedom, but his son asserts that he was a true-born Athenian. However this may be, he was poor enough to be a schoolmaster, with which Demosthenes upbraids his rival as if it were a low and sordid profession. 'While a boy,' says Demosthenes, 'thou wast brought up in great poverty, attending thy father in the school, making ink, cleaning the benches, and sweeping the school,—occupations such as befit a slave, and not a free-born youth.' The imputations which this great proficient in the art of abuse cast on the mother of Æschines were of a still less equivocal character. Æschines, when he was a little older, if we trust the testimony of Demosthenes, became a kind of clerk to some of the inferior magistrates, an occupation perhaps not unlike that of a clerk to a country justice. His next step was somewhat bolder: having a good voice and a fine person, he tried his fortune on the stage, though his success was probably not great. Whether he stepped from the stage direct into the more busy theatre of public life, we do not know; but he did finally come forward, though not at an early age, as a public man. Æschines had two brothers, one of whom, Philochares, like himself, had been a clerk or secretary; the other, Aphobetus, is said by Demosthenes to have got his living by painting alabaster vases or vessels; but Æschines denies this too. Demosthenes asserts that Æschines and Philochares served also as *public* clerks for two years. By having discharged his functions as a clerk, and having been in the service of the orators Aristophon and Eubulus in some similar capacity, he had acquired some knowledge of the laws of his country. In short, he was a bold adventurer, gifted with many of those qualities that are calculated to ensure success in the dubious game of political warfare.

Only three orations of Æschines are extant, all of which relate to important events in his public life. He was accused by Demosthenes, one of his fellow ambassadors, of malversation and corruption in his second embassy to King Philip, the object of which was to obtain Philip's ratification of the treaty of peace, and to this attack he replied in his oration entitled 'On Malversation in his Embassy.' Timarchus, a friend of Demosthenes, had joined in the attack on Æschines; but the orator speedily rid himself of this adversary by prosecuting him for a disreputable course of life. Æschines gained his cause, and Timarchus, according to some accounts, concluded the affair by hanging himself. The oration on this subject is called 'Against Timarchus.' The delay caused by the prosecution of Timarchus deferred the prosecution of Æschines till about three years after his return from the second embassy, which was no doubt favourable to the accused, as it tended to destroy the popular feeling against Æschines, who finally escaped from a verdict against him. The third oration is entitled 'Against Ctesiphon,' but is, in fact, an attack on Demosthenes, who replied in his famous oration called 'The Crown.' The pretext on which Æschines attacked Ctesiphon was this:—For some public services which Demosthenes had rendered to the state, it was proposed by Ctesiphon that he should receive a golden crown, but this proposition was considered by Æschines to contain clauses contrary to existing laws. He also denied the claim of Demosthenes on the ground of public services. As early as B.C. 338, Æschines had declared his intention to prosecute Ctesiphon, but the cause was not tried till B.C. 330, after the death of Philip, while Alexander was in the midst of his Asiatic conquests. Æschines lost his cause, and not having obtained one-fifth part of the votes of the jury, he was compelled to leave Athens, being unable to pay the penalty in that case required by the law. He retreated to the island of Rhodes, where, it is said, he resumed the profession of his earlier days, by opening classes for instruction in elocution, and became the founder of a school of eloquence. He is said to have died at Samos, B.C. 317.—[See DEMOSTHENES.]

To convey by description any exact idea of the style of this or any other great orator, we feel to be almost impossible; and, instead of a number of general remarks, which might only mislead, we must refer our English readers to the translations of Æschines, inadequate as they are, and as all translation must be, to reflect a faithful image of a language no longer spoken in its purity, and of a train of events belonging to a different system of social life. The Greek and Roman critics considered the Rhodian school of eloquence, of which Æschines was the reputed founder, to be characterized by a happy mean between the florid Asiatic and the dry and more sententious Athenian style. To us, of the present day, the style of Æschines appears distinguished by great perspicuity and correctness of language. His narrative and descriptive powers deserve high praise, nor are we disposed to undervalue his powers of abuse, though in this he falls far below his great rival. We have the strongest testimony to his *personal* qualifications as an orator, in the reluctant, but unambiguous manner in which Demosthenes acknowledges his own inferiority.

There are numerous editions of Æschines: the latest and best, as far as the mere text is concerned, is included in Bekker's edition of the *Attic Orators*, Oxford, 1822. One of the best editions of Æschines alone is by J. H. Bremius, 1824, 2 vols. 8vo. The Abbé Auger translated the orations and letters of Æschines into French, and inserted them in the second volume of his *Demosthenes*. The oration of Æschines against Ctesiphon, with the reply of Demosthenes, was translated into Latin by Cicero, and into German by Fr. Raumer, 1811.

There are twelve letters extant attributed to Æschines, the genuineness of which, we fear, would not stand the test of a thorough examination. It was usual, in the later ages of Greek literature, for rhetoric masters to employ themselves on fictions of this kind. [For a specimen of the style of Æschines, see the *Penny Magazine*, No. 63, p. 117].

Æ'SCHINES the *Philosopher* was one of the scholars of Socrates, and, as the story goes, the son of a sausage-maker. Three dialogues, still extant, that have usually gone under his name, after passing through the furnace of modern criticism, have been declared not to be written by him. The language of these dialogues proves them, however, to belong to an age when Greek was still written with great purity.

Æ'SCHYLUS, the son of Euphorion, and a native of Eleusis in Attica, was born about B.C. 525, and died in Sicily probably about B.C. 456. As the great father of the Athenian drama, Æschylus occupies one of the most prominent places in the history of the literature of his country. Like most of the great writers of antiquity, however, the particulars of his life that have come down to us are few and unimportant, with the exception that the warrior-poet fought bravely in the great struggles against the power of Persia, in the battles of Marathon and Salamis. In the later years of his life he visited the court of Hiero, king of Syracuse in Sicily, who, being a patron of poets and learned men, had collected around him the most illustrious writers of that day, such as Pindar and Simonides. An odd story is told of the cause of the poet's death: an eagle that was carrying off a tortoise let it fall on the great dramatist's head, mistaking the bald pate, as the story rather humourously concludes, for a stone.

Seven tragedies of Æschylus, out of a very large number that he wrote, still remain, entitled, respectively, *The Prometheus Bound; The Seven against Thebes; The Persians; The Female Suppliants; The Agamemnon; Choëphori* (libation-bearers); and *Eumenides*, or *Furies*. The three last form a continuous drama or *action*, which contains (1) the return of Agamemnon from Troy, and his murder by his wife Clytemnestra; (2) the revenge of Orestes, the son of Agamemnon, who kills his mother and the adulterer Ægisthus; and (3) the persecution of Orestes by the Furies, and his release therefrom by the sentence of the high court of Areopagus at Athens, and the casting vote of Minerva. It was usual with the candidates for the dramatic prize at Athens to write three tragedies on some connected subject, to which they added a fourth, called a satyric drama, on some subject treated in a tragi-comic style. The *Prometheus Bound* of Æschylus belongs to a set of this description, for we know that there was a play entitled *Prometheus the Fire-stealer*, and a third named *Prometheus Loosed*.

The Greek drama, in its origin, consisted simply of a chorus or company, who celebrated the festivals of some deity or hero by appropriate songs and dances. The introduction of a personage to tell some story or history was an innovation, and the connecting this narrator more closely with the chorus was a still further step towards the *drama*, a Greek word which signifies *an action*, or, in its more technical sense, *the representation of a series of events ending in some striking catastrophe*. But Æschylus carried improvement still further, by introducing a second speaker, and thus making the *dialogue*, as it really is, the *essential* part of tragedy. To the chorus, however, Æschylus still allowed a great degree of importance, as we may see from his extant plays, in which the choral songs occupy a large part. He added also to stage effect by improving the dress of the actors, and giving them masks: in this latter respect our notion of good acting, which requires the expression of the countenance to be seen, is at variance with the usage of the Athenian stage. Our practice of painting faces comes nearer to that for which the invention of Æschylus was a substitute; for we are told that Thespis, his predecessor, went about the country in a waggon, and daubed the faces of his company with lees of wine.

It is difficult to convey an exact idea of the character of Æschylus as a dramatist, to those who have not read the original. The plot or plan of his plays is exceedingly simple; the personages are few in number, and the events follow one another without any complexity or occasioning any great surprise. His language is always forcible, and the dialogue clear where the Greek text has escaped damage; but unfortunately, in the frequent copyings to which the works of ancient writers have been subjected, they have often suffered serious injury, and few have sustained more corruption than the plays of Æschylus. In consequence of this, the choral parts are often exceedingly obscure, and this obscurity is increased by the wild, unrestrained, and gigantic conceptions of the poet, which seem as if they often strove with the imperfections of language, and endeavoured to find utterance by a superfluity of expression, a heaping together of strong epithets, and the use of long compound words. In spite of these defects, which often make the poetry of Æschylus border on bombast, and afforded a fair subject of ridicule to Aristophanes in his play called the *Frogs*, we may often admire in this noble writer a real sublimity of conception, a boldness of imagination, and a power to paint what is grand and terrific in language, that for force, simplicity, and truth, we can venture to say, has never been surpassed. The reader may see a specimen from the play of *Prometheus* in the *Penny Magazine*, No. 49, p. 2, and another from the *Persians*, in No. 51, p. 18.

The play of the *Persians* derives a peculiar interest from being the only extant Greek tragedy which treats of a subject contemporaneous with the age of the writer. It was written or acted probably about eight years after the battle of Salamis, and may be considered as the most durable monument, created by Grecian genius, to commemorate the defeat of the Asiatic invader. The poet writes as he fought, with a noble spirit of patriotism, such as animates every brave man's bosom when he sees an invader dare to tread on the hearth of his beloved home. Æschylus is one of those brilliant examples from antiquity, in modern times but rarely seen, of a man whose greatness in *action* was accompanied by an equal greatness of *intellectual* powers.

There are numerous editions of the works of Æschylus. The first was printed at Venice in 1518, 8vo., in the press of Aldus, after his death; but the *Agamemnon* and *Choëphori* are both incomplete in this edition, and what there is of the *Agamemnon* is oddly enough tagged to the *Choëphori*, which has lost its beginning; consequently this edition contains only *six* plays. Perhaps the best edition of the text of Æschylus is by Wellauer, 2 vols. 8vo. 1823. There is an English poetical version of Æschylus by John Potter, and also several poetical versions of the *Agamemnon*. The Germans have several poetical translations of Æschylus; the latest is by Voss, 1826. William Humboldt's translation of the *Agamemnon* (1816) is highly spoken of.

ÆSCULA'PIUS, or more properly, according to the Greek form of his name, ASCLE'PIUS, was the god of medicine in ancient mythology. Agreeably to the intricacy and confusion which prevails on that subject, several Æsculapii are said to have existed; and it would not be easy to determine whether tradition really pointed to so many distinct persons, or had merely handed down different versions of the parentage of the same man. Cicero mentions three: the first, son of Apollo, invented the probe, and the art of bandaging wounds; the second, son of Mercury, was struck dead by lightning; the third was of mortal parentage, son of Arsippus and Arsinoe, and first practised purging and tooth-drawing. The Egyptians also had their Æsculapius (as the Greeks call him), the son of Hermes. Of these the son of Apollo was by far the most celebrated. It is he who was worshipped in splendid temples at Epidaurus, Cos, &c.; and it is to him that the tales current among the poets and mythologists refer. Of the most important of these we proceed to give a brief sketch.

Asclepius was the son of Apollo by Coronis, daughter of Phlegyas. His mother, having succeeded in concealing her pregnancy, exposed the child upon Mount Myrtium, afterwards called Titthium, in Argolis, near Epidaurus. A shepherd, missing his dog and one of his goats, sought the wanderers throughout the country; and at last found them, the dog keeping watch over a child enveloped in flames, which the goat was suckling. The herdsman, 'thinking that it was something divine,' and being frightened, went away; but he spread the marvel abroad, and it was soon noised over all the globe, that Asclepius could heal every disease, and, besides, bring the dead to life.

Another version of the story says, that Apollo, in a fit of jealousy, having caused the mother's death, the unborn child was snatched by Mercury (or, according to Pindar, by Apollo himself) from her funeral pile. This circumstance may be connected with the other story, which assigns the parentage of Æsculapius to Mercury.

According to Pindar, Apollo sent the child to be educated by the Centaur Chiron, who instructed him in medicine, as at an after-period he did Achilles. Having reached manhood, he went with Castor and Pollux on the Argonautic expedition. Returning to Greece he practised with eminent success, not merely curing all diseases, but recalling the dead to life. Among others, he did this service to Hippolytus, son of Theseus. The gods regarded this as an invasion of their privileges, and at last Zeus (or Jupiter) struck the bold practitioner dead with lightning, in consequence of a complaint lodged by Pluto, that the infernal regions were entirely depopulated by these new proceedings. Apollo revenged the death of his son by killing all the Cyclopes who forged thunderbolts for Zeus. Finally Asclepius was raised to heaven, and made a constellation, under the name of Ophiuchus, the serpent-holder; though some say that Ophiuchus is Hercules.

In the later ages of paganism, when scepticism was very prevalent, and it was the fashion to see allegory in every mythological story, the whole was thus explained: Æsculapius signified the air, the medium of health and life. The sun was his father, because the sun, shaping his course agreeably to the changes of the seasons, produces a healthy state of the atmosphere. The same spirit is visible in the names given to his daughters, which all but one bear reference to the father's art: Hygieia, health; Panakeia, universal remedy; Iaso, healing; Aigle, splendour.

In Greece, the original seat of Asclepius's worship was in the neighbourhood of his birth-place, at Epidaurus; where a splendid temple was erected to his honour, adorned with a *chryselephantine* (gold and ivory) statue, half the size of the statue of Olympian Jupiter at Athens. He was represented sitting; one hand holding a staff, the other resting on a serpent's head; a dog couched at his feet. In coins and other ancient remains, he is commonly seen with a long beard, holding a staff with a serpent twined about it. Often he is accompanied by a cock; sometimes by an owl. The cock was commonly sacrificed to him, as is familiarly known from the last words of Socrates, as reported by Plato, 'Criton, we owe a cock to Asclepius.' These animals seem meant to typify the qualities which a physician should possess; the owl being emblematic of wisdom, the cock of vigilance, the serpent of sagacity, and, besides, of long life. The latter was especially sacred to Asclepius. At Epidaurus there was a peculiar breed of yellowish-brown snakes, of large size, harmless, and easily tamed, which frequented the temple, and in the form of which the god was supposed to manifest himself. In this shape he was conveyed to Sicyon, and at a later period, B.C. about 400, to Rome, when that city, being afflicted by pestilence, sent an embassy, at the command of an oracle, to fetch Asclepius to their help, with due respect. On the ambassadors being introduced into the temple, a serpent came from under the statue, and glided through the city, and on board their ship. This, of course, was the god, who, in this bodily shape, signified his willingness to accompany them. Arriving in the Tiber, he swam ashore to the island upon which his temple afterwards was built. A few inscriptions have been found in this island relating cures, and the means employed. The means are of such a nature that the cures must have been impostures, or have been wrought by the force of imagination: most likely the former. It was customary to place similar inscriptions in all temples of Asclepius. At Epidaurus, there were stones in the sacred precinct, erected in commemoration of cures performed by the god, recording, in the Doric dialect, the names and diseases of the patients, and detailing the method of cures employed. Six of these remained when Pausanias visited the place; and, besides, an ancient pillar, commemorating the gift of twenty horses by Hippolytus, in gratitude for his restoration to life. Similar testimonials of superstition may still be seen even in our own country. At least such did exist, a few years ago, at the well of Holywell, in Flintshire.

Of the extent of Asclepius's knowledge, and of his method of practice, or rather of that which prevailed in the early ages before the Trojan war, we know little. His sons, Machaon and Podalirius, who fought before Troy, and are often mentioned in Homer, seem only to have meddled with external injuries. Pindar, in a passage of rather doubtful meaning, seems to confine the father's skill within the same limits, when he speaks of him as healing those afflicted with self-produced ulcers, wounds from brass or stone, or injuries from summer heat, or cold. His remedies, on the same authority, were incantations, soothing drinks, external applications, and the knife. There is a remarkable passage in which Plato (Rep. iii. § 14), inveighing against the effeminacy of his own times, contrasts the attention of physicians to diet, exercise, &c., with the negligence of the sons of Asclepius in these respects; quoting a passage from Homer, in which Machaon, returning from battle severely wounded, partakes immediately of a mess of meal and cheese, mixed up in strong Pramnian wine (Il. Λ. 639.) He continues, that it is not to be supposed Asclepius failed through ignorance to teach his sons *gymnastic medicine*, by which he means diet, exercise, and every sort of care by which a weak constitution can be strengthened; but rather that the god meant medicine to profit those only who had some accidental ailment, but sound constitutions. This was the reason that Machaon and Podalirius paid no attention to their patients, except to dress their wounds; if the men were sound, wine and cheese would not hurt them; if not, let them die, and make room for better men. The argument is well suited to the general tenor of Plato's book: a simpler inference is, that Asclepius did not give precepts relative to diet, and the treatment of internal diseases, because he knew nothing about the matter. The passage is, at least, good evidence as to what the Asclepian practice was supposed to be in Plato's age. Gymnastic medicine was introduced by Herodicus, B.C. about 440.

For some centuries after the Trojan war, medical science, if it deserves that name, seems to have been confined to the temples of Asclepius, in which his descendants, the Asclepiadæ, who formed the priesthood, were alone allowed to practise: until, in later times, pupils were admitted into the brotherhood, having been solemnly initiated, and sworn to conform to its rules. Probably they made a large profit of the credulity of their patients. Their presumed impostures have been roughly handled by the Athenian comic poet Aristophanes in his play of the Plutus. The most celebrated temples, besides that at Epidaurus, were those of Rhodes, Cnidos, and Cos, where Hippocrates, a native of the island, is said to have profited by the records preserved in the temple. Croton and Cyrene also possessed schools of medicine. The practice seems to have been intended chiefly to work on the imagination. The god often gave his own prescriptions in dreams and visions, and the patients were to be prepared by religious rites for this divine intercourse. Bathing, abstinence, and tranquillity, assisted by a confident hope of benefit, may often have produced very beneficial effects; and, in a long course of experience, it is more than probable that some valuable knowledge of symptoms and remedies must have been collected. Of the progress which the Asclepiadæ appear to have made, we shall speak more fully under the article Hippocrates.

ÆʹSCULUS, or the HORSE-CHESTNUT, is a genus of plants belonging to the natural order Hippocastaneæ. It consists of trees found in the temperate parts of America and Asia, remarkable for the beauty of their flowers and leaves, and for their forming in some sort a type of tropical vegetation in northern latitudes. It must not be confounded with the Æsculus of the Romans, which was a kind of oak. See QUERCUS. The best known species is the *common horse-chestnut*, Æsculus Hippocastanum, a very handsome timber tree, formerly much used for avenues, and still extensively planted wherever round masses of wood, or gay flowering trees, are required. Its bark and its nuts are also among the more useful products that the hardy trees of this climate afford. It is very singular that the native country of this species should be unknown. One writer says it inhabits the northern parts of Asia; another, that it is found in the cold provinces of India; and a third assigns it to the mountain chains of Asia Minor; while all the positive information that books really afford is, that it was brought to Vienna from Constantinople in the beginning of the sixteenth century, and was thence dispersed through all Europe. No trace of it has been met with by the botanists who have explored Nepal and the Himalaya mountains; so that India may be considered as certainly not producing it, although plants resembling the horse-chestnut (see PAVIA) have been detected by Dr. Wallich, Mr. Royle, and others, among the noble vegetation of that Indo-Siberian region. It is more likely that some of the almost unknown provinces, lying between Casbin in Persia and Balk, will prove to be the native country of the species in question. The popular name of *horse*-chestnut has arisen from the custom among the Turks of grinding the nuts and mixing them with the provender given to horses that are broken-winded. Starch is also yielded in very considerable quantity by the nuts; but they are not used in the preparation of the starch of commerce. They contain, moreover, so large a quantity of potash as to be a useful substitute for soap; on the latter account, they were formerly employed extensively in the process of bleaching yarn, but are now seldom used. The powder of the dried nut excites sneezing; the bark, which contains a great deal of tannin, is not a bad substitute for Peruvian bark in fevers; and, finally, the starch of the nuts, deprived of its bitterness by maceration in weak ley, has been recommended as excellent nutritious food for horses, goats, oxen, and sheep. The general characters of the horse-chestnut are too well known to require description. As a forest tree, it is well adapted to light lands, upon which it will thrive, although they may be very sterile; in tenacious clay, it is always stunted and unhealthy, as in the Regent's Park; in rich alluvial soil, it acquires its greatest beauty. The timber is soft and spongy, and therefore of little value. There are no very old specimens in this country, the species having been introduced, as it is said, only in 1683; one of the most ancient is now growing opposite the Roebuck Inn, in the village of Lewisham, in Kent, of which the following is a view.

[Æsculus, or the Horse-Chestnut.]

Two varieties of the horse-chestnut are cultivated by gardeners; namely, the gold-striped and the silver-striped, but they are mere curiosities.

A second species, the *Æsculus Ohiotensis*, is found wild in North America, on the banks of the Ohio, between Pittsburgh and Marietta. In stature it varies from ten to thirty-five feet; and differs from the common kind in having larger and much more undulated leaves. In America, it flowers very early in the spring, producing large bunches of blossoms of a pure white. It has been cultivated for some years in this country, but has never flowered.

Besides these, a third species, *Æsculus carnea*—or, as it is sometimes called, *Æsculus rubicunda*, or *rosea*—is occasionally met with in gardens. Its origin is unknown; it differs from the common horse-chestnut in not attaining so large a size, and in having deep rose-coloured blossoms of striking beauty. For all purposes of ornament, this is much superior to the common kind.

Under the genus Æsculus it is customary to include the *buck's-eye chestnuts* of North America; but, as these species have a peculiar habit, and a fruit the surface of which is destitute of the spines with which the shell of the horse-chestnuts is armed, they are now distinguished by the generic name of PAVIA, which see.

The two first species of horse-chestnut are propagated by sowing their seeds either in the autumn at such a depth below the surface as to be secure from the attacks of mice, or else in the spring; but in the latter case they must be preserved during the winter in heaps of sand. The seeds should not be placed less than six inches apart in the beds, because the leaves are so large as to require more than usual space to expose themselves to light. The last species, and the varieties of the first, not yielding seeds, are multiplied by budding upon the common horse-chestnut.

ÆSOʹPUS, now commonly called ÆSOP, a Grecian author, who lived about the middle of the sixth century

B. C., contemporary with Solon and Pisistratus. He is usually acknowledged as the inventor of those short moral fictions to which we especially appropriate the name of fables. The popular stories of him are derived from a Life, written and prefixed to a collection of Fables, bearing the name of Æsop, by Maximus Planudes, a Constantinopolitan monk, about the middle of the fourteenth century. This contains a distorted view of the few incidents in his history which can be said to be known, mixed with a long series of dull buffoonery, and improbable or impossible adventures, and represents Æsop himself as a monster of personal deformity, apparently for the sake of contrasting his wit and acuteness with his bodily defects. This life is now given up, by general consent, as totally unworthy of credit; yet Æsop's ugliness is still commemorated in almost every account of him, although it depends for its acceptation solely, as we believe, on the justly-contemned authority of Planudes, and probably was devised to attract readers by a strong dose of the marvellous. There is no allusion to these personal peculiarities in any classical author, and strong negative reasons have been urged for believing that none such existed. See *Bentley's Dissertation upon Æsop*, subjoined to that upon Phalaris.

Rejecting these idle and vulgar fictions, if we seek for information in elder writers, there is little to be found relating to the personal history of Æsop. The place of his birth, like that of Homer, is matter of question; Samos, Sardis, Cotiæum in Phrygia, and Mesembria in Thrace, laying claim alike to that honour. The early part of his life was spent in slavery, and the names of three of his masters have been preserved: Dinarchus, an Athenian, in whose service he is said to have acquired a correct and pure knowledge of Greek; Xanthus, a Samian, who figures in Planudes as a philosopher, in order that the capacity of the slave may be set off by the incapacity of the master; and Iadmon, or Idmon, another Samian, by whom he was enfranchised. He acquired a high reputation in Greece for that species of composition which, after him, was called Æsopian, and, in consequence, was solicited by Crœsus to take up his abode at the Lydian court. Here he is said to have met Solon, and to have rebuked the sage for his uncourtly way of inculcating moral lessons.

He is said to have visited Athens during the usurpation of Pisistratus, and to have composed the fable of Jupiter and the Frogs for the instruction of the citizens (Phædrus, 1. 2). Being charged by Crœsus with an embassy to Delphi, in the course of which he was to distribute a sum of money to every Delphian, a quarrel arose between him and the citizens, in consequence of which he returned the money to his patron, alleging that those for whom it was meant were unworthy of it. The disappointed party, in return, got up a charge of sacrilege, upon which they put him to death. A pestilence which ensued was attributed to this crime, and in consequence they made proclamation at all the public assemblies of the Grecian nation, of their willingness to make compensation for Æsop's death, to any one who should appear to claim it. A grandson of his master Iadmon at length claimed and received it, no person more closely connected with the sufferer having appeared. This singular tale rests on the authority of Herodotus, and as it must have taken place, if not within his own knowledge, at least within the memory of many with whom he might have conversed, we cannot doubt the truth of the relation.

The time of Æsop's death is uncertain. Some place it as early as the 53d Olympiad, about 565 B.C. If, however, there be any truth in the scattered notices which we have combined, he was at Athens during the usurpation of Pisistratus, and met with his death in the service of Crœsus, and, therefore, before the capture of Sardis and fall of the Lydian kingdom. This, according to Newton's chronology, would fix his death in the 57th or 58th Olympiad, between the years 550 and 544 B.C. The Athenians erected a statue in his honour, from the hand of the celebrated sculptor Lysippus.

There is abundant proof that fables, passing under the name of Æsop, were current and popular in Athens during the most brilliant period of its literary history, and not much more than a century after the death of the supposed author. The 'drolleries of Æsop' (*Αἰσωπικὰ γελοῖα*) are mentioned by Aristophanes in terms which lead us to suppose that they were commonly repeated at convivial parties. Socrates, in prison, turned into verse 'those that he knew;' and Plato, who banishes the fictions of Homer from his ideal republic, speaks with high praise of the tendency of those of Æsop. Demetrius Phalereus made a collection of Æsopean fables, and we hear of two metrical versions of them, of still later date, one by an anonymous author, the other by Babrius. Phædrus published a collection of fables in Latin verse, in the time of Tiberius, the materials of which he professes to have taken from Æsop; and it is not improbable that the nearest approach to the substance of the original apologues may there be found. There is another collection, written in elegiac verse, in the fourth century, by Avienus.

There is no ground whatever for believing that the Greek prose fables, which pass under the name of Æsop, are really of his composition, at least that they came from his hands in their present state. Those which are substantially the same with the fables of Phædrus, the oldest to which we can assign a certain date, may be believed, for the reasons already assigned, to have originally emanated from the Grecian author. The total number of them is about 290 or 300, and they may be divided into two principal parcels: those published by Planudes, in number 144, which contain internal evidence that, as far as composition is concerned, they are of late date, and probably written by Planudes himself; and a second collection, of 136, first published in 1610 by Neveletus from manuscripts at Heidelberg. It is to be observed that not one of these MSS. contains the fables published by Planudes; and that the editor expresses his belief that they are the work of different hands. Some he attributes to the monks, because they contain allusions to the monastic life; which is, at least, sufficient evidence of their late date. This edition, which is a sort of *corpus fabularum*, contains 297 fables ascribed to Æsop, and 40 of the rhetorician Aphthonius, who lived in the third century; besides various metrical versions in Greek and Latin.

The eastern philosopher and fabulist Lokman is supposed by many to have been the same person as Æsop. The former, by the Mohammedan authorities, is made contemporary with David and Solomon; but his history is too uncertain for us to speculate upon it. It is, at least, certain that the same fables are to be found current under the names of each, and that the correspondence between their personal histories, as commonly told, is too close to be entirely accidental. [See BABRIUS, LOKMAN.]

ÆSTHE'TICS (*Æsthetik*) is the designation given by German writers to a branch of philosophical inquiry, the object of which is a philosophical theory of the beautiful, or, more definitely expressed, a philosophy of poetry and the fine arts, and which has by them been raised to the rank of a separate science. The word *Æsthetik* is derived from the Greek verb *αἰσϑάνομαι*, (I feel, or I am sensible,) and was first used as a scientific term by Alexander Baumgarten, a disciple of Christian Wolf, who in his *Æsthetica* (Frankfort, 1750-58, 2 vols. 8vo.) considered beauty as a given property of objects, of which we are *becoming sensible*. We perceive beauty, says Baumgarten, wherever we meet with perfection manifested in reality, and a thing is perfect if it is adequate to its notion: beauty, accordingly, is the perfectness of an object manifested in its appearance. The impulse to a deeper research into the essence of beauty was given by Winkelmann, who, without embodying his views in a regular system, developed them chiefly in reviewing and appreciating the remains of ancient sculpture. He adopted neither Baumgarten's 'adequateness of an object to its notion,' nor the sensual principle which had been proposed by Edmund Burke as the criterion of beauty; but considered the idea of beauty as dwelling in the divine mind, and as passing over from that source into individual objects. Kant denied the possibility of a strict science of beauty, inasmuch as beauty, according to him, is not a property of objects, but has its origin in the disposition of our mental faculties. We presuppose, says he, that some notion is contained in the apparent object, though we are unable abstractedly to express that notion; we assume that a tendency towards some purpose has presided over the formation of the manifold variety displayed before us, though we cannot precisely define that purpose,—and this supposition or assumption forms the basis of our perception of beauty. Schelling's view of beauty and art it is difficult to state concisely. His 'System of transcendental idealism' establishes the principle, that mind and nature, or conscious and unconscious existence, are primarily identical; that the laws discoverable in nature must accordingly be traceable to the laws of consciousness, whilst, *vice versâ*, the laws of consciousness must admit of being recognized as being likewise the laws of nature; in the divine mind both exist in absolute identity. The artist is to produce in his mind an intellectual intuition analogous to this identity, and the expression which he gives to the identity thus arrived at is the work of art. Beauty, according to Schelling, is that manifestation of the principle of art where the infinite appears contained in, or represented by the finite, or where, in the very object, the difference between the conscious and the unconscious (mind and nature) is annulled.

The above meagre definitions may serve in some measure to characterize the points from which some of the principal German philosophers have started in their respective systems of æsthetics. We think it not irrelevant to remind our readers that it is almost impossible to condense within a few words what it would require a dissertation fully to explain and to discuss; and also, that the opinions of any philosopher reported in a foreign language are always apt to appear to disadvantage, but more particularly so when the language in which they were originally expressed affords such wonderful facilities for the utterance of speculative thought as the German.

Most German writers, who have published systematic treatises on æsthetics, have, with greater or less independence, followed the principles laid down by Baumgarten, Kant, or Schelling. They commonly divide their systems into a general part, or a discussion of the essence of beauty and art, and a special one, or an inquiry into the peculiar character and predominant principles of the several branches of poetry on the one hand, and the fine arts (chiefly sculpture, architecture, painting, and music) on the other.

The following are some of the most popular German works on æsthetics. Krug's *Geschmackslehre oder Æsthetik*, in his *System der theoretischen Philosophie*, Königsberg, 1806-10. Ast's *System der Kunstlehre*, Leipzig, 1805; also, *Grundriss der Æsthetik*, Landshut, 1807, and *Grundlinien der Æsthetik*, Landshut, 1813, by the same author. Jean Paul's (F. Richter's) *Vorschule der Æsthetik*, 2d ed. Stuttgart, 1813. Bouterwek's *Æsthetik*, 2d ed. Leipzig, 1815. Solger's *Erwin: vier Gespräche über das Schöne und die Kunst*. Berlin, 1815, and his *Vorlesungen über Æsthetik, herausgegeben von K. W. L. Heyse*, Leipzig, 1829.

ÆSTUARY, a term sometimes used in geographical description, and generally in the sense of 'a wide opening at the mouth of a river, in which the tide rises and falls.' Thus, the outlet of the Mersey at Liverpool, that of the Humber at Hull, and the Solway frith, may be called æstuaries. The name has been derived from a Latin word *æstus*, which sometimes signifies 'a violent motion of the sea-water.'—[See BAY and GULF.]

ÆTHER, a Greek word now used to signify a highly volatile, penetrating, and combustible fluid, several kinds of which may be produced by the action of different acids upon spirit of wine or alcohol. That which was first prepared, and which is still most employed, is the sulphuric æther, procured by distilling a mixture of sulphuric acid and alcohol. This æther we shall first describe, as affording an example of the most perfect kind, for it consists, like the alcohol from which it is made, entirely of oxygen, hydrogen, and carbon, but in different proportions. It contains none of the acid used in its preparation, whereas some kinds of æther, presently to be noticed, owe their peculiar properties to an admixture of the acid employed in forming them.

Sulphuric æther may be obtained by the following process. pour a pint[*] of alcohol into a retort, add gradually to it a pound of sulphuric acid, occasionally shaking the mixture, and distil, with a fire rather quickly raised, into a cooled receiver, about ten ounces; add half a pint of alcohol to the residue in the retort, and distil about nine ounces, or continue the operation until the contents of the retort begin to froth, or the product becomes considerably sulphurous; mix the two products, and if the mixture consist of a light and a heavier fluid, pour off the former, which is a mixture of æther, alcohol, and water, and add potash to it as long as it can be dissolved. A dense liquor is formed by the solution of the potash in the alcohol and water, and upon this the æther floats, which is to be poured off into a retort, and about nine-tenths of it are to be distilled. This product is sulphuric æther, still containing, however, some alcohol; it possesses the following properties: it is a colourless, transparent liquid, of a pleasant smell, and a pungent taste, extremely exhilarating, producing a degree of intoxication when its vapour is inhaled by the nostrils. Its specific gravity is .750, but it may be procured as low as .700, and, according to some authors, still lower than this by distillation from chloride of calcium. Æther is extremely volatile, and when poured from one vessel to another, a considerable portion of it evaporates. During evaporation much cold is produced, as may be experienced by letting some fall on the hand. Or if we put some into a small glass vessel surrounded with cloth, and containing water, and after dipping it two or three times into æther, allow the æther after each immersion to evaporate, the water in the glass freezes by the cold produced. In the open air æther boils at 96°, and in a vacuum at 20° below zero; were it not, therefore, for the pressure of the atmosphere, it would always exist in the gaseous state. The density of the vapour of æther is to that of atmospheric air, about as 2.5844 to 1, consequently it is a very dense elastic fluid. Æther remains liquid even when exposed to a cold of 58° below zero, or 90° below the freezing point of water. It combines sparingly with water, but with alcohol in all proportions. Æther, and the vapour which rises from it, are very inflammable, and during combustion, water and carbonic acid are formed by the union of its hydrogen and carbon with the oxygen of the air. When æther is admitted to any gaseous body it increases its bulk, and with oxygen gas thus expanded, it produces an inflammable and very explosive mixture. When the vapour of æther is passed through a red hot porcelain tube it is decomposed. If a small portion of æther is put into chlorine gas, the gas is absorbed, and a peculiar compound is formed in which muriatic acid is perceptible; and if the æther be inflamed, charcoal is deposited, and muriatic acid gas is evolved. When a little æther is poured into a large jar of warm chlorine, it sometimes occasions considerable explosion, the force of which the jar should be strong enough to withstand.

The resins, several of the fixed, and almost all the volatile oils, are dissolved by æther; it dissolves a small portion of sulphur and of phosphorus: the latter solution becomes luminous in a dark room, when poured on the hands or on hot water. The fixed alkalies, potash and soda, are insoluble in æther, but readily soluble in alcohol, and upon this difference of power depends the process of separating these fluids as already described. When æther is added to a solution of gold or platina in an acid, the metals are dissolved by the æther, and the greater part of the acid is separated. These solutions have been employed for coating steel instruments so as to protect them from rust. Though the deposit formed upon the steel from a solution of gold is more beautiful, that yielded by platina is stated to be most effectual. The purpose, however, to which æther is principally applied is, that of a stimulant and antispasmodic.

To render intelligible the process of ætherification by sulphuric acid, it will be requisite to exhibit a comparative statement of the composition of

Alcohol		and Æther.	
Four atoms of carbon	6 × 4 = 24	Four atoms carbon	24
Two atoms of oxygen	8 × 2 = 16	One atom of oxygen	8
Six atoms of hydrogen	1 × 6 = 6	Five atoms of hydrogen	5
	46		37

It appears then that 37 parts of æther contain as much carbon as 46 of alcohol, and the difference between their composition will be shown, by the annexed view, to be derived from the separation of the elements of an atom of water from the alcohol.

	Carbon,		Oxygen,		Hydrogen.		
Alcohol	24	+	16	+	6	=	46
Æther	24	+	8	+	5	=	37
leaving			8	+	1	=	9 an atom of water.

It was supposed by MM. Fourcroy and Vauquelin, that in this process, as actually occurs in some others, the oxygen and hydrogen were separated from the alcohol by the direct action of the sulphuric acid, on account of its affinity for water, and although water is really formed in the operation, yet it has been shown by Mr. Hennell, that its production is not direct but intermediate;—he found that, when sulphuric acid is merely mixed with alcohol, a portion of the acid immediately undergoes great change of properties, by combining with the carbon and part of the hydrogen of the alcohol. The new compound thus formed was first accurately examined by Vogel; it is called sulphovinic acid, and consists of—

Two atoms of sulphuric acid	40 × 2 = 80
Four atoms of carbon	6 × 4 = 24
Four atoms of hydrogen	1 × 4 = 4
	108

---

[*] In the chemical articles in this work the pound directed to be used is the avoirdupois, and the pint the imperial.

It will appear, from the annexed statement, that the formation of sulphuric acid is necessarily attended with that of water, thus :—

Carbon, Hydrogen, Oxygen.
Alcohol 24 + 6 + 16 = 46
Sulphuric acid 80 + 24 + 4 = 108 sulphovinic acid.
Consequently there remain 2 + 16 = 18 two atoms water.

When the sulphovinic acid is heated, decomposition ensues, and the sulphuric acid in its original state remains in the retort, while the carbon and hydrogen with which it constituted sulphovinic acid, combine with the elements of one of the two atoms of water formed from the alcohol, and æther results from their union, thus :—

Four atoms of carbon 6 × 4 = 24 } from the sulphovinic acid
Four atoms of hydrogen 1 × 4 = 4 } decomposed
One atom of hydrogen 1 }
One atom of oxygen 8 } from the water formed
One atom of æther 37

One atom of water, formed from the oxygen and hydrogen of the alcohol, remains in the retort with the sulphuric acid, which, although unchanged in its nature, is so weakened by this addition, that it cannot, in the second operation, form as much æther as in the first; on this account it will be observed that we have directed only half a pint of alcohol in the second, instead of a pint, as in the first distillation.

The elements which form æther may be regarded as existing in two modes of combination—first, as constituting a ternary compound of oxygen, hydrogen, and carbon; and secondly, as resulting from the union of two binary compounds, viz., water and bicarburetted hydrogen (olefiant gas): thus 8 parts of oxygen and 1 of hydrogen form 9 of water, and 24 of carbon + 4 of hydrogen constitute 28 of olefiant gas. Although it is entirely hypothetical, yet some plausibility is given to this view of the subject by comparing the specific gravity of the vapour of æther (which, as has been already stated, is nearly 2.5844) with that which would result from the condensation of one volume of the vapour of water and two volumes of olefiant gas into one volume; the specific gravity of this compound would by calculation be 2.569, which certainly comes very near the experimental specific gravity of the vapour of æther.

Sulphurous acid has been mentioned as arising during the action of the sulphuric acid and alcohol upon each other; and as its production is not accounted for in the explanation which has been given of the formation of æther, it is proper to state that it is an accidental and not a necessary result. When more sulphuric acid is used than is required to convert the alcohol into sulphovinic acid, the excess decomposes and is decomposed by the alcohol, so as to leave charcoal in the retort, and evolve sulphurous acid. Mr. Hennell found, after an operation in which the proportions of acid and alcohol had been nicely adjusted, that only 1-75th part of the sulphuric acid was lost, no charcoal was deposited in the retort, nor was any sulphurous acid evolved. Mr. Hennell also proved that sulphovinate of potash and sulphuric acid, if but little water was present, yielded æther, without using any alcohol; but if more water was employed, then the product was alcohol, without any æther.

Phosphoric æther is prepared by the action of phosphoric acid upon alcohol; the phosphoric acid appears to be converted into phosphovinic acid, as the sulphuric is into sulphovinic; the æther produced is precisely similar to sulphuric æther.

Arsenic acid also forms æther when distilled with alcohol; the acid probably undergoes changes similar to the sulphuric and phosphoric acids, and the resulting æther is of the same kind. (Lassaigne, *Annales de Chimie et de Phys.* t. xiii. p. 294.)

Thenard and Gay-Lussac (*Recherches Physico-Chimiques*, ii. 39) discovered that fluoboric acid and alcohol produced æther by their mutual action; the product is of the same nature as the foregoing, but the acid appears to abstract the elements of water from the alcohol by direct action, and without undergoing the changes suffered by the sulphuric, phosphoric, and arsenic acids: this, therefore, must be considered as the simplest case of the formation of æther.

It will be observed, that the acids which occasion the formation of the æthers already described do not enter at all into their composition; but in those now to be mentioned, *be ætherizing* medium generally forms a part of the product.

Chloric æther may be obtained by heating in a retort a mixture of 10 parts of alcohol, 10 of sulphuric acid, 13 of common salt, and 6 of peroxide of manganese; the distilled product is to be mixed with water, and the æther which floats on it is first to be washed with a weak solution of potash, and then with pure water. Chloric æther thus obtained is colourless, of an agreeable odour, and an acrid taste. Its specific gravity is 1·134. It boils at a lower temperature than water, is very combustible, burns with a green flame, yields muriatic acid during combustion, and leaves a residue of that acid after it. It is composed of 55·45 parts of chlorine and 44 55 of bicarburetted hydrogen in 100 parts. This æther is applied to no use.

Muriatic æther is prepared by distilling a mixture of strong muriatic acid and alcohol. It is colourless, and has a strong penetrating æthereal smell; its taste is slightly sweet; its specific gravity is ·774, according to Thenard, but other authorities make it heavier. It is extremely volatile, and consists of muriatic acid and the elements of olefiant gas. Although it does not redden litmus paper so as to evince the presence of an acid, yet when it is burnt a large quantity of muriatic acid is developed. Hydriodic and hydrobromic æther appear to be analogous in nature to muriatic æther; they are not applied to any use.

Nitric æther is prepared by distilling a mixture of equal weights of nitric acid and alcohol; the acid must be gradually added to the spirit, in order to prevent the violent action which would otherwise ensue. The distillation is to be carried on with a slow fire, and the product redistilled from lime. Its properties are, that it is of a yellowish colour, and quite neutral when freshly prepared, but it becomes acid by keeping; its smell is peculiar and æthereal, and its taste pungent. Its specific gravity about 0·886. It is extremely inflammable. MM. Dumas and Boullay state its composition to be equivalent to an atom of sulphuric æther + an atom of hyponitrous acid, or 100 parts consist of

Carbon	32·69
Azote	19·00
Hydrogen	6·88
Oxygen	41·43
	100

The acids of vegetable origin, as the acetic, benzoic, citric, gallic, oxalic, and tartaric, are capable of converting alcohol into æther, and they all enter into the composition of the æther which they form. The only one of any importance is the first named, viz. the acetic æther, and this only will be described. Acetic æther may be prepared in several modes, the following is, perhaps, one of the best:—put into a retort three parts of acetate of potash, three parts of alcohol, and two parts of sulphuric acid; distil to dryness, and mix the product with one-fifth of its weight of sulphuric acid, and distil with a gentle heat three parts of æther. This æther is colourless, it has a smell of sulphuric æther and acetic acid; it does not change litmus paper, its taste is quite peculiar, and its specific gravity is 0·866. It burns with a yellowish light, and acetic acid is developed. When mixed with potash and subjected to distillation, its odour and taste are lost, alcohol is condensed in the receiver, and acetate of potash remains in the retort. It is composed of

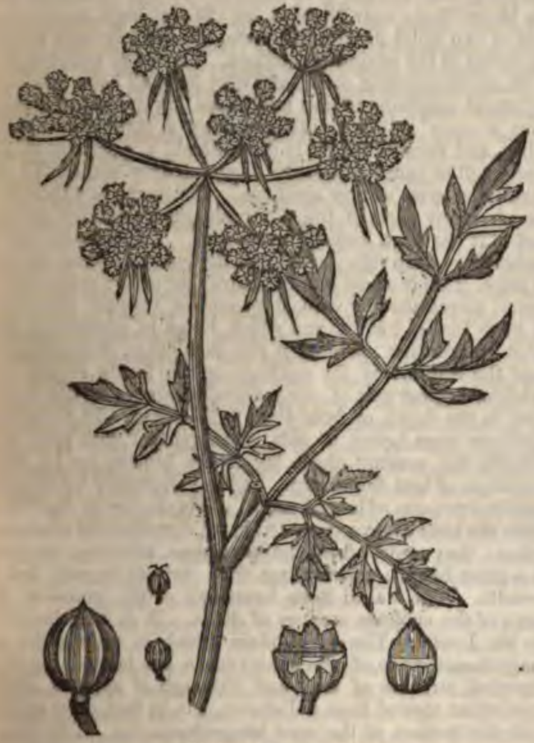
Carbon	54·65
Oxygen	36·28
Hydrogen	9·07
	100

It is sometimes, though rarely, used in medicine.

ÆTHIOPIA. [See ETHIOPIA.]

ÆTHU'SA is a genus belonging to the natural order Umbelliferæ, which includes among its species one of the most poisonous plants known in Europe. As many fatal accidents have occurred from the incautious use of its leaves, we shall give a minute description of it, for the purpose of enabling our readers to recognise it with certainty.

Æthusa Cynapium is a little annual plant, found commonly in gardens and fields, resembling the Common Parsley so much, that it has acquired the vulgar name of *Fool's Parsley*. From a taper whitish root arises an erect branchy stem, about a foot high, generally stained with purple near the ground. This is covered by finely cut shining leaves of a deep green, much resembling those of Garden Parsley, from which they are known thus: in the *true Parsley*, the leaves are twice pinnated or divided, and the leaflets are broad, and cut into three wedge-shaped toothed lobes; in the *Fool's Parsley*, on the other hand, the leaves are thrice pinnated, and the leaflets are narrow, sharper, and jagged; besides which, the leaves of Fool's Parsley have a disagreeable nauseous smell, instead of the fine aromatic odour of Common Parsley. When in flower, Æthusa has its principal umbels destitute of involucra, while the partial umbels are furnished with an involucrum, consisting of four or five narrow, sharp leaves, hanging down *from one side only* of the common stalk; this last circumstance will distinguish it when in flower, not only from parsley, but from all other British umbelliferous plants.



[Æthusa Cynapium.]

Many dangerous accidents have occurred from mistaking this plant for parsley. In one case, a person, who had eaten it with salad, died in little less than an hour; and in another of recent occurrence, the patient, although the stomach was emptied at a very early period, sank gradually, and died at the end of a few days. The symptoms attendant upon poisoning by Æthusa are, swimming of the head, nausea, cold perspiration, and chilliness at the extremities. To counteract its effects, emetics are recommended, and the immediate use of weak vegetable acids, such as lemon-juice, vinegar, or sour wine.

ÆTNA, a celebrated burning mountain, or volcano, in Sicily; it is situated in the north-eastern part of the island, close to the sea-coast, between the towns of Taormina and Catania, distant from one another twenty-five English miles, and is encircled on the north, west, and south by the rivers Alcantara and Simeto. It was called by the Arabs, after the conquest of the island, *Jebel en nar*, or 'Mountain of Fire:' the modern Sicilians call it Mongibello, which is evidently derived from the Italian *Monte* and the Arabic *Jebel*, both signifying mountain. The division of Sicily in which Ætna is situated is called Val Demone, in allusion to the popular notion that the mountain fires issue from the region of demons. It is the greatest volcano in southern Europe, and affords not only a most instructive field for studying that remarkable class of geological phenomena, but exhibits some of the most striking instances of the later revolutions which the crust of the earth has undergone, previous to the historical era; as well as of those changes which are in a constant state of progress, to a greater or less extent, on every part of the earth's surface. To convey a just idea of the structure of this remarkable mountain, it is necessary to begin with a brief sketch of the geological formation of the adjoining country. Sicily, and especially Ætna, has been described by many naturalists, but we are indebted to Mr. Lyell for the most comprehensive general views respecting this volcano, and his observations, from having been recently made, are more in accordance with the present state of science.*

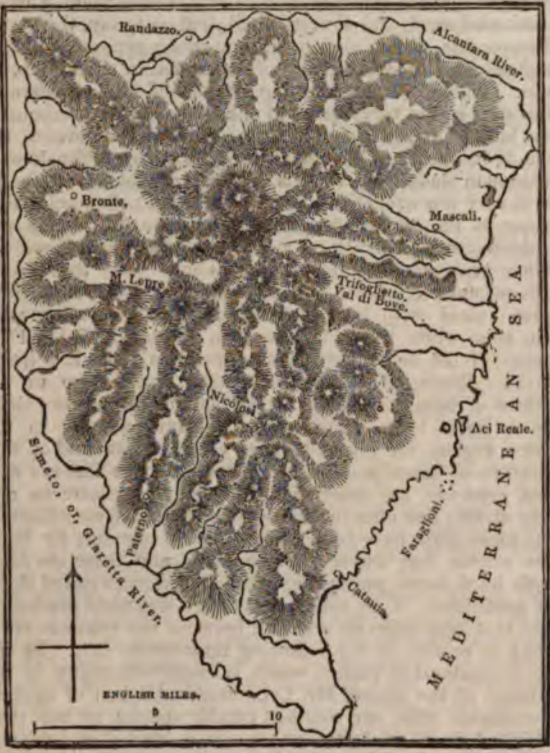
The Val di Noto, or southern division of Sicily, is composed of a series of strata, belonging to what geologists term *the tertiary period;* that is, such as have been deposited while some of the species of animals now found in our seas were in existence; all the animal remains occurring in the strata that lie *under* the tertiary rocks belong to species of which there are now no living analogues. These strata in Sicily are associated with lavas and other volcanic products, but these last are not visibly connected with any source, as no volcanic vent exists in any part of the Val di Noto. The uppermost of the strata consist of limestone, full of shells, their united thickness being sometimes as much as 800 feet; beneath these comes a slaty sandy limestone with pebbles of limestone, then a blue marl containing numerous shells, called in Sicily *Creta*,—under that, a white laminated marl, and lowest of all, that is to say, the lowest discoverable, a blue clay containing much gypsum, sulphur, and sulphate of strontian, all of them often in beautiful crystals. The great limestone deposit is found at a considerable elevation in the very centre of the island, for the summit of the hill of Castro Giovanni, 3000 feet above the level of the sea, is composed of it. All the strata, except the lowest, abound in shells, and, what is truly remarkable, these shells, with very few exceptions, can be identified with species now living in the adjoining sea. Thus, as we find shells imbedded in the solid rock, at a height of 3000 feet above the Mediterranean, belonging to species inhabiting that sea at this moment, it follows, that those parts of Sicily must have been raised from the deep to that great elevation after the time when the Mediterranean became inhabited by many of the same species of animals as those now living in it. During the time that these strata were in the course of being deposited at the bottom of the sea, there must have been considerable volcanic activity in the same region, for layers of hard compact lava, and of that mixture of ashes and limestone called by the Italians *tufo* and *peperino*, are interposed between the calcareous and clay strata; and after the whole series had been consolidated, the mass must have been violently rent asunder, for there are cracks that traverse all the beds, and these are filled with hard lavas, presenting those appearances called *dykes* by geologists. That these strata were deposited gradually, and that long intervals occurred between the volcanic eruptions, is proved by the following remarkable fact. In the neighbourhood of Vizzini, which is twenty-five miles in the interior of the island, Mr. Lyell observed a bed of oysters, identifiable with our common eatable species, no less than twenty feet in thickness, resting on a current of lava, and covered by a second mass of lava and peperino.

The Val di Noto is separated from the Val Demone and the region of Ætna by the extensive plain of Catania, which is watered by the Simeto and its tributary streams. On the northern side of the plain, as we approach Ætna, we discover a low line of hills, which are composed of the *inferior* clay stratum of the Val di Noto, and the same argillaceous formation may be traced round the base of the mountain on the south and east, the strata dipping in various directions, sometimes *towards* the mountain, so that, in their prolongation, they would lie under the volcano. These sub-Ætnean strata do not rise in any part to a greater elevation than 1000 feet above the sea, and are usually much lower: in some places they are 300 feet thick without any mixture of volcanic matter; in others, as in the vicinity of Catania, they are composed of volcanic tufo, thinly laminated, and form there a steep inland cliff from 600 to 800 feet high, separated from the sea by a low flat, composed of recent lava and volcanic sand. The sea-cliffs, northward of Catania, are formed of the same sub-Ætnean marine strata, as are the rocky islands lying off this coast, the Faraglioni, the celebrated Cyclopean islands, hurled by Polyphemus against Ulysses and his crew. The largest of these is 200 yards from the land, about 300 in circumference, and 200 feet in height, and is formed of strata of marl resting on a mass of lava, in regular basaltic columns, like the Giant's Causeway in Ireland, or Fingal's Cave in Staffa. This lava appears to have heaved up the stratified marly clay, for it is contorted in the most extraordinary manner, and is in some places hardened by the action of heat. These islands, therefore, have not been formed, as has been sometimes supposed, by a stream of lava from Ætna, for the lava of the islands underlies a stratum which underlies the volcano.

---

* A considerable part of our information is derived from the third volume of the *Principles of Geology*, which, perhaps, may not be published when this article appears. The author liberally permitted us to refer to the printed sheets.

Such, therefore, is the nature of the soil from out of which the stupendous volcano has arisen. Whether it has been formed by successive eruptions subsequently to the elevation of Sicily above the level of the sea, the observations hitherto made do not enable us to decide; it is more probable that it was partly formed prior to that elevation, and rose at the same time; and it may have projected as a cone from the surface of the water, vomiting forth volcanic matter, as Stromboli now does. But this will be better understood when we have described the structure of the volcano as it now presents itself, and have given an account of some of the most remarkable eruptions.



[Plan of Ætna, from Captain Smyth's survey.]

The base of Ætna covers an area of nearly ninety miles in circumference, and, according to the late measurement of Captain Smyth, the highest point is 10,874 feet above the level of the sea. Owing to this great elevation, the higher parts of the mountain have a climate almost as different from the valleys at its foot, as are the polar from the equatorial regions; and from this cause, together with the difference in the nature of the soil, there are three great natural divisions or zones in the mountain, the fertile, the woody, and the desert. The lowest is called the *Parte Piemontese*, merely expressing that it lies at the foot of the mountain: it is a beautiful, rich, and populous country, covered with luxuriant fields of corn, vines, and fruit trees. The limit cannot be very well defined, as it insensibly blends with the next, the *Regione Selvosa*, or the woody, which is covered by immense forests of chestnuts, oaks, beeches, and pines, forming a zone six or seven miles in width, the superior limit being about 6300 feet above the sea. The third and highest region, called the *Parte Scoperta*, the bare or desert, rises nearly 4600 feet higher. About 1100 feet from the summit there is an irregular plain, which, when Sir W. Hamilton visited it, about sixty years ago, was estimated to be nine miles in circumference, and from this plain rises the steep terminating cone, at the summit of which is the great crater or opening, continually throwing out sulphureous vapours. The dimensions of the crater have been very variously stated by different travellers, the circumference from two and a half to four miles, and the depth from 600 to 800 feet; but the height of the cone, the diameter of the crater and its depth, are liable to constant change from the eruptions. The cone has more than *once fallen* in and been reproduced: in the year 1444 it was 320 feet high, and fell in after the earthquake of 1537. In 1693, when a violent earthquake shook the whole of Sicily and killed 60,000 persons, the cone lost so much of its height, that it could not be seen from several places in Val Demone, where it was before visible. Although, taken as a whole, Ætna forms a cone which is in general of a very symmetrical form, when examined in detail it is found to be studded on its flanks, and particularly in the woody region, with numerous minor cones; small when compared with the great mass, but of a magnitude that would make them rank as mountains, if detached. One of the largest, called Monte Minardo, near Bronte, is upwards of 700 feet in height, and the Monti Rossi near Nicolosi are 450 feet high, and have a base of two miles in circumference, although ranked among the cones of the second magnitude. There are about eighty of these considerable cones, and they have all been produced by lateral eruptions of lava and ashes. By subsequent eruptions a cone is often surrounded by a lava stream or by ashes, and thus its height is diminished: a repetition of the process often causes its entire disappearance under the accumulated mass of new ejections. The sections exposed to view in many parts of the mountain show that the greater part of it has been formed in this way. The eastern side is broken by a deep valley of colossal dimensions, called the *Val di Bove*. This is a vast amphitheatre four or five miles in diameter, surrounded by vertical precipices, varying from 1000 to 3000 feet in height, and which, taken in connexion with other valleys that lead into it and each other, descends from near the summit to the confines of the fertile region, and exhibits a great part of the internal structure of the mountain, to the depth of from 4000 to 5000 feet. In these sections are seen layers of tufo interstratified with lava, and, towards the summit, these layers are broken up by fresh eruptions of lava from below, and are disturbed by the successive intrusion of lateral cones. We also see in the Val di Bove the beds of lava traversed in all directions by enormous dykes: they project from the precipices, towering vertically to a great height, and varying from two to twenty feet in breadth. The Val di Bove forms one of the grandest features of the sublime scenery of Ætna. It is thus described by Mr. Lyell: 'The great plain which is inclosed by the magnificent circle of precipitous rocks has been deluged by repeated streams of lava, and although it appears almost level when viewed from a distance, it is, in fact, more uneven than the surface of the most tempestuous sea. The face of the precipices is broken in the most picturesque manner by the vertical walls of lava which traverse them. These masses usually stand out in relief, are exceedingly diversified in form, and often of immense altitude. In the autumn, their black outline may often be seen relieved by clouds of fleecy vapour which settle behind them, and do not disperse until mid-day, continuing to fill the valley while the sun is shining on every other part of Sicily, and on the higher regions of Ætna. An unusual silence prevails, for there are no torrents dashing from the rocks, nor any movement of running water in this valley, such as may almost invariably be heard in mountainous regions. Every drop of water that falls from the heavens, or flows from the melting snow and ice, is instantly absorbed by the porous lava; and such is the dearth of springs, that the herdsman is obliged to supply his flocks during the hot season from masses of snow laid up in hollows of the mountain during winter. The strips of green herbage and forest land, which have here and there escaped the burning lavas, serve, by contrast, to heighten the desolation of the scene. When I visited the valley, nine years after the eruption of 1819, I saw hundreds of trees, or rather the white skeletons of trees, on the borders of the black lava, the trunks and branches being all leafless, and deprived of their bark, by the scorching heat emitted from the melted rock. This vast cavity in the mountain has none of the characters of a crater, but has probably been produced by a combination of different causes: by great subsidences, by lateral explosions, and by the great floods by which, even in historical times, it has been known to have been devastated, when a fiery torrent of lava had suddenly overflowed a great depth of snow in winter. The phenomena of the Val di Bove, as well as the position of the sub-Ætnean strata, are quite at variance with Von Buch's theory of the elevation of volcanoes from *craters of elevation;* a theory which, like another of that celebrated geologist, has not stood the test of rigid examination, and which has been too hastily adopted by many eminent naturalists, from the faith we are naturally inclined to repose in an authority, which we know to be entitled to great respect.

The records of history supply no materials from which we can arrive at any knowledge of the gradual growth of the mountain, for the additions to it from the accumulated produce of all the eruptions that have taken place within the period of history, great as they are, become quite insignificant when contrasted with the entire mass of the volcano. But if we compare the time that has elapsed since that comparatively thin covering began to be formed, with that which must have been required to produce, by a similar process, the remaining part, we shall form the most exalted notions of its remote antiquity. We have no ground for supposing that the altitude of Ætna has materially varied within the last 2000 years. Of the eighty most conspicuous lateral cones, not one of the largest has been produced within the period of authentic history. Every eruption does not produce a lateral cone, for one in three takes place from the crater at the summit; also when an opening is made in the flanks, a cone is not always produced, and many eruptions must have taken place from the sides, besides those which raised the eighty cones above-mentioned. We know, also, that there have been great intervals of rest between the eruptions, almost a century in some instances; so that, according to all probability, we must date the origin of the earliest of these cones, some thousand years prior to the historical era. But we may reasonably carry our views of the antiquity of the volcano much beyond even that remote date. If we were to remove the whole of the cones as well as the entire matter which has been ejected from them and from the highest crater during the period of their growth, we should cut off several miles of the diameter of Ætna at its base, and diminish its elevation by some hundred feet; but we should still leave a mountain more lofty than any other in Sicily. That stupendous mass of volcanic matter must have been ejected subsequently to the formation of stratified rocks containing the remains of animals identifiable with those now living in the adjoining seas; rocks, be it remembered, among the most recent of the whole series of strata of which the crust of the earth is composed.

There are not more than sixty eruptions recorded in history, from the earliest to the present times. Of these, ten happened before the Christian era, twelve in the next fifteen hundred years, seventeen during the sixteenth and seventeenth centuries, and twenty-one from that time to the present; the most recent having taken place in November, 1832. The most remarkable would alone be noticed, and it is probable that many occurred in the second period of which we have no record; although a cessation for the whole period of fifteen hundred years would be in no degree at variance with the history of other and neighbouring volcanoes, for the island of Ischia enjoyed an interval of repose from the devastation of its internal fires for seventeen centuries. Diodorus Siculus (lib. v. c. 2.) speaks of old eruptions of Ætna, said to have taken place long before the Trojan war, and to have occasioned the emigration of the Sicani, the earliest inhabitants of the island, who were afterwards replaced by the Siculi from Italy. An eruption is recorded to have occurred in the time of Pythagoras, who is believed to have died 496 B.C. Another took place 475 B.C., and it is to this eruption that Æschylus and Pindar most probably allude, the one in his play of Prometheus, the other in the following passage of his first Pythian ode.—It was a poetical fiction or a popular superstition that the great giant Typhos was buried beneath Sicily, and, according to Pindar, the outstretched monster spread as far as the volcanic regions about Cuma and Naples.

‘The sea-girt heights above Cuma, and Sicily too, press upon his shaggy breast; and the pillar of heaven, snowy Ætna, the perennial nurse of sharp pinching snow, holds him fast. From the recesses of Ætna are vomited forth the purest streams of fire, immeasurable in extent. By day the fiery current pours forth a burning torrent of smoke, but by night, the red flame, rolling along masses of rock, plunges them with loud crash into the surface of the sea. That monster sends up such horrid streams of Hephæstus (Vulcan)—a sight wonderful to look on; wonderful, too, to hear of from those who have seen it.’

An eruption is mentioned by Thucydides 425 B.C., which did some damage to the lands of Catana, as Catania was then called; and he adds, that this was the third eruption of lava on record since the Greeks had been settled in Sicily. Diodorus Siculus (lib. xiv.) mentions an eruption 396 B.C. which stopped the Carthaginian army in their march from Messina to Syracuse, and obliged them to go round the whole base of the mountain in order to reach Catania. This stream of lava may be seen on the eastern slope of the mountain near Giarre, extending over a breadth of more than two miles, and having a length of twenty-four from the summit of the mountain to its final termination in the sea. There are similar notices of later eruptions which we do not think it necessary to particularize; for a mere list of dates would afford no interest to the general reader, and there is such a similarity in the phenomena, varying only in intensity, that it would be tedious and unprofitable to give a description of the several instances of activity in the volcano. We shall content ourselves with a notice of some of the most remarkable eruptions of which detailed accounts have been preserved. In 1537, after violent rains and great devastations occasioned by the flooding of the river Simeto, Ætna was rent in several places, and from the openings there poured forth deluges of liquid lava. They directed their course towards the monastery of St. Nicholas d'Arena, destroyed the gardens and vineyards, and proceeding towards Nicolosi burnt two villages and destroyed most of the inhabitants. When the conflagration ceased, the summit of the mountain sunk in with a terrific noise. These agitations of the mountain continued throughout the whole year. The smoke, noise, and shocks of earthquakes affected the whole island. In 1669 an earthquake had levelled to the ground all the houses in Nicolosi, a town situated near the lower margin of the woody region, about twenty miles from the summit of Ætna, and ten from the sea at Catania. Two gulfs then opened near that town from whence sand and scoriæ were thrown up to such an amount, that, in the course of three or four months, the double cone we have mentioned in a previous part of this article, called Monti Rossi, was formed. It is about 450 feet high, and two miles in circumference.

In the plain of S. Lio, a fissure six feet broad and of unknown depth opened with a loud crash, and ran in a somewhat tortuous course to within a mile of the summit of Ætna, traversing a length of twelve miles, and emitting a most vivid light. Five other parallel fissures of considerable length opened one after the other, and sent forth smoke and bellowing sounds, which were heard at the distance of forty miles. The light emitted from the great rent of S. Lio appears to indicate that it was filled to a certain elevation with incandescent lava, probably to the height of an orifice not far distant from Monti Rossi, which at that time opened and poured out a lava current. This stream, after overflowing fourteen towns and villages, some with a population of between 3000 and 4000 inhabitants, at last reached the walls of Catania, which had been purposely raised to protect the city; but the burning flood accumulated till it rose to the top of the rampart, which was sixty feet in height, and then fell in a fiery cascade and overwhelmed a part of the city. The wall, however, was not thrown down, and the solid lava may still be seen curling over the top of the rampart like a cascade in the act of falling. This great current had performed a course of fifteen miles before it entered the sea, where it was still 600 yards broad and forty feet deep.

The eruption of 1792 is thus described by Ferrara:—On the first days of March the mountain emitted thick clouds of smoke, and at night flames were seen to rise to a considerable height. On the 8th it shook violently, and for several days awful roarings were heard, which appeared to proceed from the innermost cavities of Ætna. During April the mountain was tolerably quiet, except that smoke and flames were occasionally seen issuing from its summit. In the beginning of May immense masses of smoke rose in perpendicular columns, and on the 11th lava was seen to flow from the great crater. Meantime shocks of an earthquake were felt at Messina; and on the morning of the 12th the internal roaring was repeated, the black smoke rose in the air in the shape of a gigantic tree, spreading its top to an immense extent around, and in the midst of these dense masses of black smoke were seen numerous globes of white smoke as fleecy as cotton. Towards eleven o'clock A.M. of that day, an explosion, like the discharge of heavy artillery, was heard and felt all around the base of Ætna, followed by a hollow rumbling noise, and the black smoke arose with fresh violence. In the evening the lava flowed down the sides of the mountain in several streams, one westward towards Aderno, and another ran to the south-east into the valley of Trifoglietto, and stopped at Zoccolaro, ten miles from the crater. On the 13th, the mountain became more quiet, and remained so till the 23rd, only sending forth a shower of ashes and hot sand, which fell all around its sides. On the 23rd the black smoke re-appeared; and the next day a new mouth opened itself in the plain Del Lago, about three miles south-east of the great crater, and from it, for several days, blocks of old lava and scoriæ were thrown to a great height, as well as masses of clay, moist and soft. On the 26th, another mouth opened in the same direction, and vomited a stream of lava which fell into the valley of Trifoglietto, and soon after all the old lava cliffs above tumbled down, and nearly filled the valley. On the 1st of June, a large mouth opened itself half-way up the southern side of the cone of the mountain, on the heights called Del Solfizio, facing Catania, and from it a huge torrent of lava issued forth, ran down the immediate slope beneath, then, turning eastward, rushed against the base of Mount Arcimisa, one of the numerous conical hills which rise round Ætna. The stream was then forced round into a valley 400 feet deep which had been formed by the waters, and which sloped down to the eastward into the cultivated plain and the vineyards. The lava soon filled up the valley, where it began to harden; but the liquid stream from the heights still pouring in pressed against it, so that now and then an enormous mass of half-hardened lava would detach itself, and having slidden some distance down the declivity would break up with a tremendous crash into a thousand fragments, and cover a fresh extent of ground. The lava stream covered, in this manner, the vineyards of Zaffarana, and approached the village of that name, when it fortunately stopped close to the houses from whence the inhabitants were all ready to fly. The sight is described by Ferrara as extremely awful and grand, especially by night. The eruption continued for a whole year, till May, 1793. The stream of lava, in its fluid state, was often thirty feet high. The lava that flowed first cooled, and became condensed at a certain distance, and thus formed a dyke against the current of fresh lava which swelled up and overflowed its own bed, increasing in height at every fresh overflowing. Thus in many places strata of lava have been formed more than 300 feet high. The stream of lava sweeps the ground on which it flows, carrying along with it the earth, stones, trees, and other substances which it finds in its passage. At a short distance from the mouth the lava becomes covered with a crust of scoriæ, which increases in thickness progressively, the lower part of the stream continuing to flow underneath like a liquid paste. The scoriæ sometimes form bridges over the fiery stream sufficiently strong to bear a person.

In 1819, three large mouths or caverns opened very near those formed in an eruption eight years before, from which flames, red-hot cinders, and sand were thrown up, with loud explosions. A few minutes afterwards another mouth opened below, from which flames and smoke issued; and finally, a fifth, lower still, from whence a current of lava flowed, which spread itself with great velocity over the Val di Bove. The three original mouths at length united into one large crater, and sent forth lava, as did the inferior apertures, so that an enormous torrent poured down the great valley. When it arrived at a vast, and almost perpendicular precipice, at the head of the valley of Calauna, it poured over in a cascade, and, being hardened in its descent, made a tremendous crash as it was dashed against the bottom. So immense was the column of dust raised by the abrasion of the tufaceous hill over which the hardened mass descended, that the Catanians were in great alarm, supposing a new eruption to have burst forth in the woody region, exceeding in violence that near the summit of Ætna.

The following account of the eruption in the beginning of November, 1832, is by Professor Gemmellaro, of Catania, whose letter is dated the 15th of November. 'On the 31st of October, at half past two in the afternoon, several tremblings of the earth, accompanied with fearful subterranean noises in the woody region of Ætna, announced an eruption; but as the mountain was enveloped in clouds, the place could not be exactly ascertained. In the middle of the night, however. it appeared very evident that the volcano had broken out in two places, one of which was at the foot of the highest cone towards the S.W., at a height of 9300 feet. From several small orifices of the crater, ashes, sand, and cinders were thrown out; and one of them poured forth an inconsiderable stream of lava, in the direction of the Casa Gemmellaro, but the old lava stream of 1787 served as a dyke, and caused it to change its direction. The lava now flowed into the valley of Trifoglietto, towards the Cone San Simone (eruption of 1811), the distance it had travelled from its source being about two miles. But these appearances were of minor importance, in comparison with an eruption which took place in the neighbourhood of Monte Lepre, N. W. of the crater, eight miles distant from Bronte, and at an elevation of 6200 feet in the upper part of the woody region, near where it ends. Here four mouths of fire were opened, out of which, not only ashes, sand, and cinders, were projected to a vast height, but also enormous red-hot masses: the earth shook during these catastrophes without ceasing, and the subterranean noises were fearful. The explosions from the highest of the openings were very powerful, and continued without intermission. A pillar of flame rose to the height of 120 feet, which, falling at some distance, formed an arch of fire; and what was particularly remarkable, there was a dark blue stripe which rose upwards to a great height, and was a constant accompaniment of the eruption for several days. The four other mouths were not less active a stream of lava burst forth from the lowest of them, which now threatens to be fearfully destructive: in five days it extended to the distance of four miles; it threatened first the woods of Maretto, but turned afterwards to those of Bronte. In the course of its rapid descent, the lava soon began to spread itself over cultivated fields, and did considerable damage: it is at this time only three miles distant from Bronte, a town of 13,000 inhabitants, which it threatens with destruction. The terrified inhabitants see the most dreadful fate awaiting them; part have fled in the greatest despair, others have been endeavouring, like the people of Catania at the time of the terrible explosion of 1669, to make the lava stream take another direction, but it is impossible to approach it within a quarter of a mile. At the moment I am closing this letter, I am told that the lava is within two miles of Bronte, and that to-morrow night the fate of the unhappy town will be decided; for the stream has reached a point from which it must either flow into a side valley, or inevitably overflow Bronte. On the 11th of this month, the five mouths united into one, the violence of the eruption increased, and the quantity of ashes and cinders thrown out was enormous; the finest ashes have been carried as far as this place. The lava is augitic, and contains very few crystals; the cinders are light, spongy, and half-vitrified.' The distance of Catania from Bronte is twenty-five miles in a direct line. Happily, the destruction of Bronte has, for the present, been averted, for we learn by a letter dated the 22nd of Nov., the following further particulars. 'On the 16th, the alarm of the inhabitants began to diminish. Nothing could be more terrific than the first appearance. A stream of lava, dividing itself into two branches, eighteen miles long, including all its windings, a mile broad, and thirty feet high, threatened to overwhelm the defenceless land. There was also a great alarm lest it should fall into the bed of the Simeto, and cause a frightful inundation of the neighbouring country. The greater part of the lava has poured into a large gulf previously opened, and the earthquakes have ceased. A new cone has been thrown up, similar to those around the flanks of Ætna, which attest its former eruptions. The town of Bronte has been saved, no lives have been lost, and altogether the damage done is less than was at first apprehended."

For more than half the year, the upper part of the mountain is covered with snow; and it forms the great store from whence Sicily and Malta are supplied in summer with that necessary of life in a hot climate, yielding a considerable revenue to the bishop of the diocese, and constituting a great article of commerce. 'A remarkable discovery,' says Mr. Lyell, 'has lately been made on Ætna, of a great mass of ice, preserved for many years, perhaps for centuries, from melting, by the singular accident of a current of red-hot lava having flowed over it. The following are the facts in attestation of a phenomenon which must at first sight appear of so paradoxical a character. The extraordinary heat experienced in the south of Europe during the summer and autumn of 1828 caused the supplies of snow and ice which had been preserved in the spring of that year, for the use of Catania and the adjoining parts of Sicily, and the island of Malta, to fail entirely. Great distress was felt for the want of a commodity regarded in these countries as one of the necessaries of life, rather than as an article of luxury, and on the abundance of which, in the large cities of Sicily, the salubrity of the water, and the general health of the community, are said in some degree to depend. The magistrates of Catania applied to Signor M. Gemmellaro, in the hope that his local knowledge of Ætna might enable him to point out some crevice or natural grotto on the mountain where drift snow was still preserved. Nor were they disappointed; for he had long suspected that a mass of perennial ice at the foot of the highest cone was part of a large and continuous glacier covered by a lava current. Having procured a large body of workmen, he quarried into this ice, and proved the superposition of the lava for several hundred yards, so as completely to satisfy himself that nothing but the subsequent flowing of the lava over the ice could account for the position of the glacier.' Mr. Lyell thus accounts for this extraordinary phenomenon. 'We may suppose that, at the commencement of the eruption, a deep mass of drift snow had been covered by volcanic sand, showered down upon it before the descent of the lava. A dense stratum of this fine dust, mixed with scoriæ, is well known to be an excellent non-conductor of heat: the shepherds in the higher regions of Ætna are accustomed to provide water for their flocks during summer, by strewing a layer of volcanic sand a few inches thick over the snow, which effectually prevents the sun from penetrating. Suppose the mass of snow to have been preserved from liquefaction until the lower part of the lava had consolidated, we may then readily conceive, that a glacier thus protected at the height of 10,000 feet above the level of the sea would endure as long as the snows of Mont Blanc, unless melted by volcanic heat from below.'

Every one is aware that, in lofty mountains, the temperature of the air diminishes as the elevation increases, and that even under the equator there are regions of eternal snow. So in Ætna, he who ascends from the sea-shore to the summit, passes through all the gradations of climate which he would meet with, were he travelling from the country of the date and the sugar-cane to the arctic circle. His own feelings would not enable him accurately to mark the transitions, but the botanist can trace the lines of separation, drawn by the hand of Nature, with unerring precision. We have said that Ætna is divided into three regions, the fertile, the woody, and the desert; these zones are defined by the presence or absence of certain great classes of the vegetable kingdom, but each of them is susceptible of subdivisions, determined by the constitutions of certain families of plants, which can only thrive within certain limited ranges of temperature; and thus the mountain is divisible into seven distinct *botanical* regions. We can mention only a few of the plants that are characteristic of each, and must refer the reader for fuller details to special works on the subject.

The *first*, or what may be termed the sub-tropical region, does not rise more than one hundred feet above the level of the sea. Here grow the palm-tree (*Phœnix*), the banana (*Musa*), the Indian fig, or prickly-pear (*Cactus opuntia*), and the sugar-cane; and there may be seen in open gardens tree-cacaliæ, and euphorbiæ, together with varieties of mimosa and acacia, which, in the northern parts of Europe, are nursed in our hot-houses and conservatories. The *second*, or hilly region, extends to the height of about 2000 feet, where the culture of the vine ceases. Here we find many plants of the South of France, Spain, and Italy, and cotton, maize, the orange, the lemon, and the shaddock. From the great dryness of the atmosphere, mosses and lichens are extremely rare, and the mushroom tribe (*fungi*) are only met with in winter. The *third*, or woody zone, lies between the elevations of 2000 and 4000 feet: it is the region of the cork-tree (*Quercus suber*), and other kinds of oak (*Q. pedunculata*, *Q. robur*, *Q. congesta*), the maple (*Acer*), and, especially on the eastern side, of luxuriant chestnut-trees, often of extraordinary size. The *fourth* region, which lies between the elevations of 4000 and 6000 feet, is characterized by the presence of the beech (*Fagus sylvestris*), Scotch fir (*Pinus sylvestris*), birch (*Betula alba*), and, among small plants, clover (*Trifolium roseum*), sandwort (*Arenaria condensata*), mouse-ear chickweed (*Cerastium album*), dock (*Rumex arifolius*), and plantain (*Plantago victorialis*). The *fifth*, or sub-alpine region, lies between the elevations of 6000 and 7500 feet, and produces the barberry (*Berberis ætnensis*), soap-wort (*Saponaria depressa*), toad-flax (*Linaria purpurea*), and juniper (*Juniperus hemisphærica*). The *sixth* region lies between the elevations of 7500 and 9000 feet. With the exception of *Berberis ætnensis*, *Astragalus siculus*, and *Juniperus hemisphærica*, almost all the plants of the fifth region are also found in this; but the *Saponaria depressa*, the *Rumex ætnensis*, and the fleshy and jagged groundsel (*Senecio carnosus* and *S. incisus*), are characteristic of it. The *seventh* region is very narrow, its upper limit not rising above 9200 feet; and it only produces a few lichens, among which the *Stereocaulon paschale* is the most common. Beyond that elevation utter sterility prevails.

It is very remarkable that the Flora of Sicily produces scarcely any, if any, peculiar indigenous species, the plants being common, almost without exception, to Italy or Africa, or some of the countries surrounding the Mediterranean, whereas there are several indigenous plants in Corsica and some other Mediterranean islands. Mr. Lyell supposes the plants of Sicily to have migrated from pre-existing lands; and, as the remains of living species of shell-fish and zoophytes are found imbedded in the strata at the summits of lofty mountains in the island, he brings us to this curious result, that the families of plants and animals of the Val di Noto, and some other mountainous regions of Sicily, are of higher antiquity than the country itself; that is, that these species flourished elsewhere before the island was raised from the depths of the sea, and even before the materials of its strata were deposited beneath the waters.

We cannot allude, even thus briefly, to the vegetable productions, of Ætna, without noticing the gigantic chestnut-tree,—one of the most celebrated wonders of the island; it occurs in the third region, and is known by the name of the *Castagno de Cento Cavalli*, because it is said to be capable of sheltering a hundred horses under its boughs. It appears to consist of five large and two smaller trees, which, from the circumstance of the barks and boughs being all outside, are considered to have been one trunk originally. The largest trunk is thirty-eight feet in circumference, and the circuit of the whole five, measured just above the ground, is one hundred and sixty-three feet. It still bears rich foliage, and much small fruit, though the heart of the trunk is decayed, and a public road leads through it wide enough for two coaches to drive abreast. In the middle cavity a hut is built for the accommodation of those who collect and preserve the chestnuts.

This is said, by the natives, to be 'the oldest of trees.' From the state of decay, it is impossible to have recourse to the usual mode of estimating the age of trees by counting the concentric rings of annual growth, and therefore no exact number of years can be assigned to the age of this individual. That it may be some thousand years old is by no means improbable. Adanson examined in this manner a Baobab tree (*Adansonia digitata*) in Senegal, and inferred that it had attained the age of five thousand one hundred and fifty years; and De Candolle considers it not improbable that the celebrated Taxodium of Chapultopec, in Mexico (*Cupressus disticha*, Linn.), which is one hundred and seventeen feet in circumference, may be still more aged.

The ascent of Ætna is a work of great fatigue, especially in the upper or desert region, both on account of the heat and of the feet sinking and receding at every step in the loose ashes. But under favourable circumstances of weather, the labour is amply rewarded by the magnificence of the vast prospect, varied as it is by the view of Sicily itself, spread out like a map, by the islands with which the surrounding sea is studded, Stromboli pouring forth volumes of smoke, and by the distant shores of Italy. If to this we add the grandeur of the scenery of the mountain itself, so diversified and majestic in all its features, the splendour of the heavens at night, and of the rising of the morning sun, the whole presents a combination perhaps not to be found on any other spot of the earth. The best accounts of Ætna are to be found in the following works: Ferrara, *Descrizione dell' Etna; Palermo.*—1818. Gemmellaro, *Quadro Istorico dell' Etna*, 1824. Daubeney, *On Volcanos*, 1826. Scrope, *On Volcanos*, and *Principles of Geology*, by Charles Lyell, 1832,3; and for the botany of Ætna, Presl, *Flora Sicula*, Prague, 1826.

ÆTO'LIA, according to the ancient geographers, consisted of two chief divisions, one on the coast, extending from the mouth of the Achelous eastwards along the north shore of the Corinthian gulf as far as its narrow entrance at Antirrhium—the other, called Epiktetos, or the acquired, was the northern and mountainous part. The length of sea-coast, as Strabo incorrectly gives it, from the mouth of the Achelous to Antirrhium, is 210 stadia, or about 21 miles: the same line of coast, according to the best modern charts, is about 42 miles, measuring in straight lines from one projecting point to another. If the great recesses of the sea about Anatolico and Mesolunghi were included, the distance would be much greater. The south-eastern boundary of Ætolia, which separated the province from that of the Locri Ozolæ, was a mountain range named Chalcis, afterwards, in its north-eastern course, taking the name of Corax. The north and extreme north-eastern boundaries of Ætolia were the small territory of Doris, the branches of Pindus, and part of the western line of Œta; but as no ancient geographer has given anything like a definite boundary to Ætolia, and as we are still only imperfectly acquainted with the mountains of northern Greece, any further description is impossible. The western boundary was the Achelous. [See ACARNANIA.]

The only considerable river of Ætolia, besides the Achelous, is the *Fidari*, formerly the Evenus, which rises in the N.E. part of Ætolia, in the range of Corax, which is some distance south of the great chain of Pindus. Its course is south, inclining in its lower course considerably to the west. Ætolia contains several lakes in the interior, two of which, as they are marked in our maps, communicate with one another and with the Achelous; but there is some difficulty in identifying these with the lakes mentioned by the ancient geographers and historians. Indeed, nearly the whole ancient and modern geography of central Ætolia is one heap of confusion. One of the lakes is called in our maps *Angelo Castro*, and the other *Vrachori*.

The principal ancient positions in Ætolia were, Thermum, in the interior; Trichonium, on the lake Trichonis, now *Vrachori;* Calydon, the oldest establishment of the Ætolians, and Antirrhium, at the entrance of the Corinthian gulf.

The Leleges in the north, and the Curetes, probably a kindred race, in the level plains of the south, are the oldest inhabitants of this country that we can trace. The name of Ætolia and Ætolians was introduced, according to tradition, by Ætolus and his followers from Elis, in the Peloponnesus, six generations before the war of Troy. In course of time the original inhabitants and the strangers formed one people, and increased by the intermixture of Æolians and Bœotians from Thessaly, they became in part, though not altogether, a Grecian people. In the time of Thucydides, one of the most numerous divisions of the Ætolian nation was characterized by that writer as 'speaking a language not understood, and being in the habit of eating raw flesh.' [Thucyd. iii. 94.]

The history of the Ætolians, as a nation, is closely connected with that of the Acarnanians, but, like the latter, they were a people of little importance during the most flourishing periods of the commonwealths of European Greece. After the death of Alexander the Great, B.C. 323, they came into notice by their contests with the Macedonian princes, who allied themselves with the Acarnanians. In the reign of Philip II. of Macedon, (which commenced B.C. 220,) the Ætolians, after seeing their chief town, Thermum, plundered by this king, and feeling themselves aggrieved by the loss of all they had seized from the Acarnanians, applied to the consul Valerius Lævinus. (B.C. 210.) Though this produced no beneficial effects, they formed a second treaty with the Romans (about B.C. 198) after the end of the second Punic war. The immediate object of the Romans was the conquest of Macedonia, but it proved eventually that this fatal alliance of the Ætolians was the first step that led to the complete subjugation of all Greece by the Romans. A series of sufferings and degradations led the way to the occupation of all Ætolia, when it was made part of the Roman province of Achæa. Under Roman dominion, the few towns of Ætolia almost disappeared: many of the inhabitants were transplanted to people the city of Nicopolis, which Augustus built at the entrance of the Ambracian gulf, opposite Actium, where he had defeated Antony. Since the time of the Romans it is probable that the face of this country has undergone as few alterations, or received as few improvements from the hand of man, as the most remote parts of the globe. The Romans themselves under the emperors had not even a road through Acarnania and Ætolia, but followed the coast from Nicopolis to the mouth of the Achelous.

Under the Turkish empire, Ætolia was partly in the province of Livadia. According to the original arrangements, only the part east of the Achelous and south of the two great lakes, was to belong to the new kingdom of Greece, but these boundaries are now extended towards the north and west, as far as the gulf of Arta.

The earliest traditions of Ætolia, properly known by that name, speak of a monarchical form of government under Ætolus and his successors; but this form of government ceased at a period earlier than any to which historical notices extend, and we find the Ætolians existing in a kind of democracy, at least during the time of their greatest political importance. This period extended from about B.C. 224, to their complete conquest by the Romans, B.C. 168, a period of about 50 years. The Ætolian league at one time comprehended the whole country of Ætolia, part of Acarnania and of South Thessaly, with the Cephallenian isles; and it had besides, close alliances with other places in the Peloponnesus, especially Elis, and even with towns on the Hellespont, and in Asia Minor. This alliance with Elis would tend to confirm the tradition of the early connexion already alluded to. Following, probably, the example of the Achæan league, the different parts of Ætolia formed a federal union, and annually chose a general or president, a master of the horse, a kind of special council called Apokletoi (the select), and a secretary, in the national congress held at Thermum about the autumnal equinox. Such scattered notices as we possess about their history and constitutional forms are found principally in the Greek writer Polybius, (books ii. iv. xvii., &c.) Though the Ætolian confederation, such as it was in its earlier times, was anterior to the Achæan union of Dyme, Patræ, &c., yet its more complete organization was most probably an imitation of the Achæan league. A minute account of this confederation, which, after all, would be little more than conjecture, is not within our plan. [See Schlosser, *Univ. Hist.* vol. ii. p. 1. Hermann, *Lehrbuch*, &c.]

AFFETTUO'SO, (Ital. *affectionate*) in music, signifies a tender, expressive style; and slowness is invariably implied. In regard to movement it may be considered as equal in degree to larghetto. See LARGHETTO.

AFFIDAVIT, in Law, is a statement of facts in writing, on oath. The word is the perfect tense of the barbarous Latin word *affido*, to pledge faith to, and is taken from the old Latin form of a declaration on oath, which commenced thus: '*Affidavit J. S.*,' 'J. S. hath sworn, &c.' By the law of England affidavits are necessary in a variety of cases, in order to bring facts under the cognizance of courts of justice all evidence of facts must be given on oath, either by oral testimony or by affidavit. Where evidence is to be acted upon by juries, it is given as oral testimony; where it is to inform a court or judge, it is usually reduced into the form of an affidavit.

In point of form, an affidavit is usually made as follows: if made in a cause, the name of the court in which the cause is pending, and the names of the plaintiff and defendant, are written at the head of the paper. The name, description, and residence of the deponent, or person making the affidavit, are written at length, and the individual making the affidavit signs his name at the foot of it. The paper is then shown to him, and he is requested to swear to his name and handwriting, and that the contents of the paper are true. And, lastly, the *jurat* (a term derived from the Latin word *juratum*, 'sworn') expressing the officer before whom, and where, and when, the affidavit is made, is signed by such officer. If the affidavit be sworn in open court, that circumstance is mentioned in the *jurat*, and no officer is named.

AFFINITY. Chemical affinity, sometimes called chemical attraction, is that power by which bodies combine and form compounds always possessing some properties very different from those of their constituents, and frequently diametrically opposite to them. It differs from the attraction of gravitation in not acting on masses, and only at sensible distances. In this last property it resembles cohesive affinity, but is distinguished from it by occurring only between the particles of dissimilar bodies. Thus, the particles of a mass of sulphur are held together by cohesive affinity, and so also are those of a mass of copper; but if a particle of sulphur be brought into contact with a particle of copper, the two particles being different, and possessing chemical affinity for each other, unite by this power, and form sulphuret of copper.

Chemical affinity, then, can be exerted only between the particles of dissimilar bodies; and when these are placed in contact, the proportions in which they combine are fixed and definite. It is, indeed, true, that there are some bodies, and especially fluids, which mix and appear to combine in all proportions. Thus, any quantities of water and alcohol (spirit of wine) may be mixed, and no separation afterwards ensues; yet though they thus *mix* in all proportions, it is probable that they *combine* chemically only in definite quantities. When common salt is added to water a certain portion of it is dissolved, dependent upon the affinity existing between the solid and the fluid.. The solution of salt is said to be saturated when the water refuses to dissolve more of it; but with water the solution will mix to any extent, for no repulsive power exists between them as between oil and water: we may, however, consider the water which is so added as merely in a state of mixture, and not of chemical combination.

Although none but dissimilar bodies unite by chemical affinity, mere dissimilarity will not of itself ensure combination: thus, water and mercury, water and oil, mercury and oil, though very different fluids, cannot be made to unite; and hence it is concluded that they have no chemical affinity for each other.

The simplest cases of chemical affinity are those in which two elementary bodies unite into a binary compound, as when iron combines with oxygen to form oxide of iron. This is the result of what is termed *single affinity*, and this power may be exerted between two elementary or two compound bodies; and also, though it occurs more rarely, between an elementary and a compound substance. For example, sulphur and copper, both elementary bodies, readily unite when heated: sulphuric acid and oxide of copper, both compounds, combine with great readiness; but no combination of sulphur and oxide of copper, or of sulphuric acid and copper, is at present known. There is then a greater disposition to combination between two elements or two compounds, than between an element and a compound· the rule is, however, by no means without exception, for cyanogen, a compound body, combines with mercury, an elementary one, to form cyanuret of mercury.

It has been mentioned that, when bodies combine by chemical affinity, they undergo great change of properties: it might, however, be supposed that a compound would possess qualities intermediate between those of its constituents. This, however, is by no means the case; nor, even though we may be well acquainted with the properties of the elements, can we at all tell, *à priori*, what kind of a compound they will form: sulphur is yellow, copper is red, but the sulphuret of copper, resulting from their union, is black. Again, sulphuric acid has great affinity for water, and, when diluted, turns vegetable blues red: potash has also great affinity for water, and renders vegetable blues green. The acid and potash are also both extremely acrid, and they have great affinity for each other; but combine them by *single affinity*, and a salt, called sulphate of potash, is produced, which has very slight affinity for water, does not act upon any vegetable colours, and, instead of being acrid to the taste, like both its constituents, is merely bitter and saline. In this case of chemical affinity an almost total reversal of properties has occurred; but there are cases in which it is far from being so complete, and in which one or both of the ingredients still exert some of their original powers: thus, the sulphate of potash, above alluded to, is capable of combining with an additional quantity of sulphuric acid. This salt, which is called bisulphate of potash, resembles both its constituents in having affinity for water, as is shown by crystallizing in combination with it, and by being readily soluble in it; and it resembles sulphuric acid in having a sour taste, and turning vegetable blues red.

We have stated a few examples of the changes produced in bodies by a combination effected by chemical affinity. The alterations, in many cases, are more striking and complete; the properties of the substance formed by the combination being altogether different from those of the bodies from which it has originated. Sulphuret of copper, as already noticed, differs in colour from both its elements, yet it resembles both in being solid; but there are numerous cases in which the form, colour, smell, taste, density, and other physical qualities, and the chemical properties of fusibility, volatility, solubility, and tendency to combination in the compound, bear no resemblance to its constituent parts.

Although, when speaking of the action which is induced by chemical affinity, chemists are frequently in the habit of stating merely that one substance has affinity for another, yet it is to be understood that the force with which bodies unite arises from mutual and equal affinity: thus, sulphuric acid and potash combine, not merely on account of the affinity of the acid for the alkali, but of the alkali equally for the acid Chemical affinity, then, is mutual and equal between those substances which combine by its power. Many different compounds may be formed by uniting one substance, an acid, for example, with various others, as with the alkalis, earths, and metallic oxides; these are called bases; and the force of affinity of any acid for any base differs in every instance. Now, this difference constitutes what has been termed *elective affinity*,—the existence of which is easily proved, and the results of its action are of the highest importance, both in a scientific point of view, and with regard to chemical agency as connected with the most common processes in the chemical arts and manufactures.

Nitric acid is capable of combining by *single affinity* with lime or with magnesia; and if some dilute nitric acid, containing 54 parts of real acid, be mixed with 28 parts of lime, the earth will be dissolved in the acid, and a neutral solution of nitrate of lime is obtained. A similar quantity of this acid forms a neutral solution of nitrate of magnesia by combining with 20 parts of that earth. Now, if we mix together 54 parts of nitric acid, 28 of lime, and 20 of magnesia, it might be supposed that the acid—which is of course incapable of dissolving the whole of both of the earths—would dissolve them in the proportions of 14 of lime and 10 of magnesia: it is found, however, that this is not the case, for the whole of the lime is dissolved and the magnesia entirely left.

It appears, then, a greater mutual affinity, or an *elective affinity*, exists between nitric acid and lime, than between nitric acid and magnesia. There is another mode in which elective affinity acts, and is employed in a vast number of chemical processes. It has been just stated that 54 parts of nitric acid combine with 20 of magnesia by single affinity. Now, if to the solution of nitrate of magnesia thus obtained we add 28 parts of lime, and boil the mixture, the lime separates the magnesia from the nitric acid; and being dissolved instead of it, we procure a solution of nitrate of lime, instead of nitrate of magnesia: this operation is termed *single decomposition*, and it is produced by single elective affinity. It is therefore evident, that this power may not only prevent one substance from combining with another when three are mixed, but supposing two to have been previously combined, it is capable of effecting a separation between them.

On the action of single elective affinity producing single decomposition, depends the process of preparing acetic acid from acetate of soda by means of sulphuric acid; and the production of ammoniacal gas by distilling a mixture of lime, sulphate of ammonia, and water.

To exhibit the degrees of elective affinity, tables were constructed by Geoffroy, a French chemist, about a century ago. In these the substance whose affinities are to be expressed is placed at the head of a column, and is separated from the rest by a horizontal line; beneath this line are arranged the bodies with which it is capable of uniting in the order of their respective forces of affinity; the substance which it attracts most strongly being placed nearest to it, and that for which it has the least affinity at the bottom of the column · thus, in the case of sulphuric acid, the affinities are exhibited in the following order:—

Sulphuric Acid.

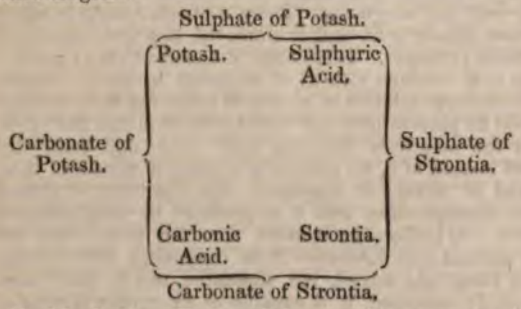
Barytes,
Strontia,
Potash,
Soda,
Lime,
Magnesia.

It would appear from this table, that barytes separates sulphuric acid from combination with all the substances placed below it, and that magnesia is separated from sulphuric acid by all that are above it. There are, however, many circumstances which interfere with the accuracy of tables thus constructed, and diminish their utility, since affinity is not an absolute force, but subject to anomalies and to modifications from various disturbing causes.

In the above, and many similar tables, the affinity of an acid for different bases is expressed; but on other occasions, the affinity of the same bases for different acids is required. In this case the alkali, earth, or metallic oxide, is placed at the head of the column, and the various acids are arranged according to their affinity for it.

There is yet another mode in which elective affinity is exerted. Certain compounds can scarcely be obtained at all, or with great difficulty, either by single affinity or single elective affinity, but are readily obtained by what is termed *double elective affinity*. There is a well-known mineral body called sulphate of strontia, which consists of sulphuric acid and the earthy base (or strictly speaking, metallic oxide) strontia, and they are combined by single affinity. Now potash has great affinity for the sulphuric acid of the sulphate of strontia; but if we mix them, no decomposition takes place, the potash being incapable, by single elective affinity, of detaching the sulphuric acid from the strontia. Again, carbonic acid and strontia have great affinity for each other, but if carbonic acid gas be passed through water in which powdered sulphate of strontia is diffused, it does not by single elective affinity separate the strontia from the sulphuric acid.

That decomposition, however, which single elective affinity cannot in this case perform, may be effected by double elective affinity, producing *double decomposition*. If, instead of acting upon the sulphate of strontia with the carbonic acid and potash separately, we combine them and boil the powdered sulphate of strontia in a solution of the carbonate of potash thus formed, double elective affinity ensues, and two new compounds are formed,—namely, sulphate of potash, which remains in solution, and carbonate of strontia, which, being insoluble in water, is precipitated in the state of a white powder. The double elective affinity which produces double decomposition will be illustrated by the annexed diagram.



Double elective affinity and decomposition are extensively employed in chemical operations; the preparation of various acids, such as the nitric and muriatic, and of a great number of saline compounds, depends upon the application of these modifications of chemical affinity. We shall now illustrate a position already stated, viz., that chemical affinity is not to be considered as an invariable power, but subject to causes which prevent, increase, or reverse its action; and it is on this account that tables of affinity express merely the order of decomposition, and not that of attraction under every circumstance. The causes now alluded to may be comprehended under *form* and *proportion*, and the modifying effects of heat, electricity, and light.

With respect to *form*, it may be observed, that the solid state is unfavourable to the exertion of chemical affinity; and it was once supposed that two solid bodies could not act chemically upon each other. That this is not the case may be proved by adding lime to muriate of ammonia, for by their mutual action ammoniacal gas is plentifully evolved. Division is, however, in all cases favourable to chemical affinity: thus, a mass of marble dissolves slowly in muriatic acid, but when reduced to powder the action is extremely rapid. In some cases mechanical division, however minute, is insufficient to allow combination: thus, if finely powdered pipe-clay be added to dilute sulphuric acid, no chemical affinity is exerted between them, the cohesive affinity of the particles of clay exceeding that of their chemical affinity for the sulphuric acid. If, however, we take a solution of alum and add ammonia to it, the clay is precipitated from it in so minutely divided a state that the acid immediately dissolves it.

When a jet of hydrogen gas is thrown upon a mass of platina, no effect whatever is produced, but when the platina is very minutely divided, then chemical affinity is excited; the platina becomes first red-hot, then inflames the hydrogen, and water is formed during its combustion.

Minute division, then, so as to reduce the cohesion of a body, is in many cases necessary to the exertion of chemical affinity, and in all cases it increases the rapidity of its action.

Fluidity is always favourable to chemical action, and in most cases it is requisite that one body, at least, should be in that form. Thus galls and sulphate of iron, though both are reduced to fine powder, do not act upon each other: dissolve either of them and add the other in powder to the solution, and chemical affinity will be exerted; but if they are both dissolved, then the action is instantaneous.

There are some instances in which affinity is but feebly, if at all exerted, unless both bodies be so finely divided as to be exposed to each other in the aëriform state: thus sulphur is capable of combining with alcohol. Little of it is, however, dissolved by the spirit when it is merely powdered; but if the sulphur and alcohol be heated in separate vessels, and their vapours be suffered to mix, they then unite.

The nascent state of bodies is one which is extremely favourable to the action of chemical affinity. Chlorine has affinity for silver, and the compound which they form, called chloride of silver, is white and insoluble in water; hydrogen has great affinity for chlorine, and they combine to form muriatic acid. If, however, hydrogen gas be passed into water holding chloride of silver in suspension, no change occurs, for the hydrogen has not, under these circumstances, the power of separating the chlorine from the silver.

If the hydrogen be evolved in the vessel which contains the suspended chloride of silver, it has then an opportunity of coming into contact with it in its *nascent state*, that is at the moment of its separation from combination, and before it has assumed the state of gas. Under these circumstances the hydrogen separates the chlorine from the silver, muriatic acid is formed, and metallic silver separated. It is, however, easy to combine chlorine and hydrogen gases by exposing a mixture of them either to the sun's rays, the taper, or the electric spark. But the gases which constitute ammonia, viz., hydrogen and azote, do not unite unless one of them, at least, is in the nascent state: thus if iron filings moistened with water are exposed to azotic gas confined over mercury, ammonia is produced, for the water is decomposed by the iron, its nascent hydrogen unites with the azote to form ammonia, and its oxygen with the iron to form the oxide of that metal.

The nature of the compounds, arising from the chemical affinity and action of their elements, is greatly influenced by the *proportion* of the substances employed to produce them. When equal weights of sulphuric acid and alcohol are subjected to distillation, the product is sulphuric æther; double the quantity of acid, and oil of wine is obtained; use ten parts of acid to one of alcohol, and olefiant gas is formed by their mutual action. Again: if a mixture of two parts of nitre and one part of sulphuric acid be distilled, there are produced nitric acid and sulphate of potash; but if a part of the sulphate of potash be dissolved in the nitric acid, nitrate of potash will be again formed, accompanied with bisulphate of potash.

There are several other cases which prove that the proportions of the substances which act chemically upon each other, greatly influence the nature and proportions of the new compounds formed: thus, when 100 parts of sulphate of barytes are boiled in a solution of 59 parts of carbonate of potash, 23 of the sulphate are decomposed and converted into 19·3 of carbonate. When also 85 parts of carbonate of barytes are boiled in a solution of 74 of sulphate of potash, decomposition also takes place, and there are formed 67 of sulphate of barytes, and 40 of carbonate of potash. In these experiments, then, it appears that decomposition cannot in either case be entirely effected, while the new compounds formed remain in mixture with the portions of the original salts which remain undecomposed. In other words, there takes place a partition of bases between the acids whose action is opposed to each other.

Heat, according to its degree and under various circumstances, produces very different effects on chemical affinity, and causes, increases, reverses, or prevents its action. If we mix oxygen and hydrogen gases, they will remain in a state of mixture for an indefinite period without combining; but if flame be applied to them they combine with explosion, and water is formed. Water dissolves certain salts, but to a limited extent only when cold; boil it and the solvent power is greatly increased. When mercury is moderately heated in atmospheric air it is converted into peroxide, by combining with the oxygen of the air: heat the compound thus formed more strongly than was required for its production, and the affinity is destroyed; oxygen gas is given out, and the mercury returns to its metallic state. Mix solutions of chloride of calcium and carbonate of ammonia; double decomposition ensues; carbonate of lime and muriate of ammonia result. Evaporate the mixture to dryness, and heat the residue; the order of affinities is reversed, and chloride of calcium and carbonate of ammonia are reproduced: in this case, heat reverses the order of affinities. There is one instance, however, in which heat produces effects that are quite anomalous and irreducible to any idea of their dependence upon degree of temperature; it is this:—when the vapour of boiling water is passed over ignited iron, the water is decomposed; hydrogen, one of its elements, is evolved in the state of gas; and oxygen, the other, combines with the iron and converts it into oxide. Now if we ignite this oxide of iron and pass hydrogen gas over it, the oxide is decomposed, its oxygen combines with the hydrogen, and water is re-formed. No satisfactory explanation of the laws of affinity, by which these opposing results are obtained, has hitherto been offered. These facts afford an illustration of the disturbing causes which very much limit the usefulness of tables of affinity. According to the first experiment, oxygen and iron combine in preference to oxygen and hydrogen, whereas it appears from the second that the affinity of oxygen for hydrogen exceeds that for iron. But it is evident that these statements are irreconcilable with each other; and as the temperature is in both cases the same, no variation of it can account for the incompatible results of the experiments.

Electricity possesses remarkable power over chemical affinity: if the electric spark be passed through a mixture of oxygen and hydrogen gases, it causes them to combine, and water is formed by their union. It is, however, probable that this and some similar effects are produced by the heat which accompanies the electrical spark; but there are other cases of combination which must perhaps be attributed to specific action, as, for example, when nitric acid is formed by the agency of electricity upon atmospheric air.

The action of electricity is much more remarkable in causing decomposition than combination, and especially that form of it which is termed voltaic electricity, or galvanism; the first substance decomposed by it was water. When two platina wires are connected with the poles of a voltaic trough, and their unconnected ends are immersed in water, hydrogen-gas is evolved at the negative, and oxygen-gas at the positive wire. Many other compound bodies have been similarly decomposed: their elements separate at the opposite poles, and the same body always appears at the same pole: thus in all decompositions, oxygen, chlorine, and the acids go over to the positive surface, while hydrogen, the metals, inflammable substances in general, and the alkalis, are found at the negative surface.

In common electrical attraction, the bodies attract each other in consequence of their opposite electrical states; and in the same manner, in the electro-chemical theory proposed by Sir H. Davy, it is supposed that acids and other substances which are attracted in electrical decompositions to the positive pole, are negatively electrical at the moment of their separation from combination; and on the contrary, the alkalis, which are found at the negative extremity, are positively electrical.

It has, however, by no means been proved that chemical affinity is identical with electrical attraction; and we must yet consider it as a peculiar species of attraction, subject indeed to the control of electrical agency, which is capable, not merely of decomposing compounds, but of suspending chemical action and reversing the order of affinities.

If sulphate of soda be dissolved in a blue vegetable infusion and subjected to voltaic electricity in a glass tube, it is soon found that the fluid at the positive pole becomes red, indicating the presence of an acid, while at the negative it is green, showing the action of an alkali. In this case the sulphate of soda is not only decomposed, but its constituents, while under electrical influence, appear to be incapable of recombining; for, by reversing the position of the tube, or the places of the wires, the fluid which was red will become green, and the green red: thus proving that, while under electrical influence, chemical affinity is suspended, for the acid and the alkali must have passed through the same solution without combining.

That affinity may be controlled by altering the electrical state of a body, is also proved by Sir H. Davy's very curious experiments on copper-sheathing, which, though they failed from unforeseen causes, are worthy of his genius. It appeared to Sir H. Davy that the copper was oxidized by the atmospheric air in the sea-water, and that then it took muriatic acid from muriate of magnesia and formed with it submuriate of copper, and hence ensued the destruction of the metal. Now, as metals combine with acids only when oxidized, it occurred to Sir H. Davy, that if he could render the copper negative, which is the electrical state of the oxygen, they would not combine. This he effected by bringing the copper into contact with zinc or iron; these being rendered positive, the copper became negative, scarcely combined at all with oxygen, and was so little acted upon by the muriate of magnesia in sea-water, that when protected by only 1-1000th part of iron, oxidizement and conversion into submuriate were, to a certain extent, prevented.

The following will also serve as an example of the reversal of chemical affinity by electricity. Immerse a piece of copper in a solution of nitrate of silver; the copper is dissolved and the silver precipitated: if we reverse the experiment, and put a piece of silver into a solution of nitrate of copper, no change is effected; if, however, the silver while immersed be touched by a piece of iron, a voltaic circuit is formed, the order of affinity is reversed, the copper is precipitated, and the silver is dissolved.

Light is capable of controlling chemical affinity both with respect to decomposition and combination. If a mixture of hydrogen and chlorine gases be exposed to the sun's rays, they combine with explosion, and form muriatic acid· this effect does not appear to be produced by the heat which accompanies the light, for a considerably higher temperature is not capable of producing the combination. With respect to the decomposing agency of light, it is well known that if pale nitric acid be subjected to it, it suffers decomposition to a certain extent, oxygen gas being evolved: it is also found that some metallic oxides which retain the oxygen with but slight force of affinity, evolve it and are reduced to the metallic state by the agency of light.

In concluding the subject of chemical affinity it is to be observed, that substances often combine in more than one proportion of each, and the quantities are governed by certain laws, which will be considered under Atomic Theory.

AFFINITY, in Law, means a relationship by marriage, The husband and wife being considered, in law, as one person, those who are related to the one by blood, are related to the other in the same degree by *affinity*. This relationship not being the effect of nature, but the result of civil institution, the persons between whom it exists are said to be related *in law*; the father or brother of a man's wife being called his *father* or *brother-in-law*. Almost the only point of view in which affinity is a subject of any importance in the English law is, as an impediment to matrimony;—persons related by affinity being forbidden to marry within the same degrees as persons related by blood. [See Marriage.] It is in consequence of this rule that a man is not permitted, by our law, after his wife's death to marry her sister, aunt, or niece,—those relations being all within the prohibited degrees of *consanguinity*; and therefore, according to the principle just laid down, the prohibition extends to the same relations by *affinity* also. This rule, which excludes from marriage relations by affinity within certain degrees, is founded upon the Levitical law; and doubts have been entertained by very learned writers, whether its introduction into the municipal laws of modern countries is necessary or useful. [See Michaelis, *Mosäisches Recht*. b. iii. c. 7.]

AFFIRMATION, in Law, is the solemn asseveration made by individuals belonging to the class of Dissenters called Quakers, in cases where an oath is required from others. This indulgence was first introduced by the statute 7 and 8 Wil. III., chap. 34, which enacts that the solemn affirmation of Quakers in courts of justice shall have the same effect as an oath taken in the usual form. The provisions of this statute are explained and extended by 8 Geo. I., chap. 6, and 22 Geo. II., chap. 46, sect. 36; but in all these statutes there is a clause expressly restraining Quakers from giving evidence on their affirmation in criminal cases. This absurd exception, which Lord Mansfield called 'a strong prejudice in the minds of the great men who introduced the original statute' (Cowper's *Reports*, p. 390), has been entirely removed by a recent enactment (9 Geo. IV., chap. 32): and Quakers and Moravians are now entitled to give evidence in all cases, criminal as well as civil, upon their solemn affirmation. A curious question arose during the present session of parliament (1833), respecting the sufficiency of the affirmation of a Quaker, instead of the customary oaths, on his taking his seat in the House of Commons; the subject was referred to a committee, upon whose report the House resolved that the affirmation was admissible.

AF'FIX, a term in Grammar, to which the name of *suffix* also is sometimes given. It signifies a *syllable* attached to the *end* of a word by which the form and signification of the word are altered. This will be best explained by some examples from our own language. Thus in the words *wealth-y*, *weight-y*, *bulk-y*, and in *god-ly*, *odd-ly*, &c., the syllables *y* and *ly* are the affixes, which qualify the meanings of the words to which they are attached, and fit them for a new and different use; as 'This man loves *wealth*;' 'That is a *wealthy* merchant.' Verbs are in this way made from adjectives, as from the adjectives *sharp*, *quick*, *thick*, we have *sharpen*, *quicken*, *thicken* respectively; and adjectives and adverbs from nouns, as in the examples just given. The *'s*, which marks our possessive case, is an affix, having originally been a distinct syllable, as we see from our old books in such expressions as *Goddes* will; *mannes* duty. Some persons are of opinion that this *'s* has arisen from the possessive pronoun *his*, as in such a phrase *God his will*, *man his duty;* but we are of opinion that this final *'s* is to be referred to the German and Anglo-Saxon genitive termination *es*. When we hear people vulgarly say *hisn*, *hern*, for *his*, *her*, the *n* is the remnant of the syllable *en*, which in these instances marks a kind of pronominal adjective, akin to the genitive or possessive case;—as we may still observe in the German forms *dessen*, &c.

In the Latin and Greek, and many other languages, there is the same system of affixes of which we have given examples in the words *weighty*, *bulky;* and in these languages the different cases of nouns, and adjectives, and the different tenses and persons of the verbs, are also formed by affixes. Thus the nominatives *Pindaru-s*, *Homeru-s*, *Liviu-s*, *Antoniu-s*, are the true Roman forms of these names, which, in the accusative, form *Pindaru-m*, *Homeru-m*, &c., respectively, and so on in the other cases. With the English, it is the common practice to shorten all these words to Pindar, Homer, Livy, Antony; and yet we are not consistent in this practice, for we say *Tibullus*, *Æmilius*, &c. keeping in these instances the genuine form just as it is in the language to which these names belong. The irregularity depends upon the greater or less familiarity of the names. With the French, the changes are still more violent.

AF'GHANISTAN is a country of Asia, extending from the Indus on the east to Persia on the west, and from the great chain of Hindoocoosh on the north towards the Indian ocean on the south. Taken in its largest acceptation, and including the nominally dependent provinces of Balkh (the ancient Bactria), Cashmere, Herat, Beloochistan, &c., the limits of the empire are the 24th and 37th degrees of north latitude, and 62° and 77° east longitude. This great territory includes a varied population of above fourteen millions, consisting chiefly of Afghans, Persians, and Indians.

The name is Persian, and, though not unknown to the Afghans, is not used by them. They have, in fact, no name for their country: they call themselves Pushtaneh.

An enormous table-land of high elevation extends from the coast of Korea to the Black Sea, varying considerably in its breadth from north to south between these two limits. It consists of two portions, of which the eastern is the higher This elevated table-land has also its elevations, or mountains; of which the Himalaya range forms the great southern boundary, the western part of which is called the Hindoo Koosh. The higher ridges of the Hindoo Koosh are bare rock, perfectly free from verdure, and in many parts covered with perpetual snow. The gentlemen of the British embassy, in June, 1809, saw no diminution of snow on this ridge, though at Peshawer, within fifty miles, the thermometer stood at 113°. It is much intersected with narrow but fertile valleys, and is finely wooded near its base. Its general height is very great, and some of its peaks are supposed to be higher than those of the principal ridge, which runs about 200 miles farther north, and is there called the Mooz Tagh, or Ice mountain. It enters Afghanistan to the north of Cashmere, crossing the Indus, which rises in the principal ridge to the N.E., and proceeds chiefly with a western direction to the high peak of Hindoo Koosh, N.W. of Cabul (long. 68°, lat. 35°), where it loses its name and character. About 71° long. the *range* sinks suddenly to receive the river Kama, which rises in the chief ridge. With this exception, all the streams which join the Cabul on the north have their sources in the Hindoo Koosh. From long. 68° a range of mountains of a lower character extends 350 miles to the west, reaching nearly 200 miles from north to south. These mountains are called by European geographers the Paropamisan mountains; they are generally cold and barren, difficult of access, and very little known. Their northern face is a rapid descent into Balkh, part of the ancient Bactria.

Another chain, inferior in height to the first mentioned, extends from the Cabul river, immediately opposite the great chain, to the 29th degree of latitude. This range is called the mountain of Soliman; it runs parallel to, and near the Indus, to which river it has a very steep descent. It is traversed by the river Gomul, whose sources are far to the west, and its continuity is doubtful in other parts. Except its northern extremity, where snow is found throughout the year, no part of the Soliman range has snow beyond the spring.

Beyond these our accounts of the mountain courses of Afghanistan are founded chiefly on conjecture. Several branches appear to extend westward from the Soliman, and they are said to join the Paropamisan; but their ranges are unknown. The southern country appears full of mountains, which reach from the south of the Soliman in parallel ridges westward to the table-land of Kelat in Beloochistan.

The whole of Afghanistan, extending south from the great ridge, is a lofty table-land, considerably elevated above the neighbouring countries. Its northern boundary looks down on the low land of Balkh or Bactria, and its eastern limit on the valley of the Indus: towards the west it slopes gradually to the desert, and on the south sinks rapidly to Beloochistan and the Indian ocean.

The rivers of Afghanistan, though of considerable length, are not large, and are all fordable during the greatest part of the year. Although many give great promise on issuing from the hills, so much of their water is drawn off for the purposes of irrigation, and so much exhausted by evaporation, that, excepting in the rainy season, scarcely one reaches the end of its channel. The Cabul, the chief of the rivers flowing eastward, is formed by various streams uniting to the east of Cabul, the capital; the rivulet which gives its name in our maps to the whole river, rises twenty-five miles west of Cabul, about 34° N. lat., 69° E. long. It is joined a little below the city by a much larger stream from the west of Ghizni; and farther east, at 70° E. long., by the united streams of Ghorebund and Punjsheer, from the mountains of Hindoocoosh. At Kama (71° E. long.), near Jellalabad, it receives the great river of Cashgar, called in our maps Kama, which issues from the Pooshtikhur, in the Beloor Tagh, near the source of the Oxus, 38° N. lat., 73° E. long. This is the most important of all the branches of the Cabul, the united stream falls into the Indus about three miles above Attock, in 34° N. lat., and 72° 20′ E. long. The names here given are those of our maps; in fact, there appears to be no general name for any river of Afghanistan; every branch has its separate appellation, and the same stream rarely retains the same name above fifty miles of its course.

The principal river of those that run westward is the Helmund, (the Etymandrus or Hermundrus of the ancient geographers,) which rises in the same range that contains the sources of the Cabul. After running about two hundred miles through mountains, the Helmund continues its course across the western desert, until it reaches the great lake of Sejestan, commonly called Zerrah.

The Helmund overflows every year like the Nile, and, like that river, spreads fertility over its banks; for though the lower part of its course is through a perfect desert, the immediate shores of the river form a fertile, populous, and well-cultivated country, called Gurmzeer.

The climate is very variable, and a region hot as India may be found within a day's journey of a perpetually frozen country. The east is generally much hotter than the west, and in the plains of Peshawer a thermometer in the shade rises to the height of 128° in July. In the same place, frost lasts to the beginning of March. The spring is very rapid; before the end of March, plum-trees and apple-trees are in full foliage; barley is in the ear; the heat is already disagreeable, and in May the very wind is hot. In the hot parts of the country, the simoom is felt occasionally: this is a hot wind, which lasts but a few minutes, but its effects are terrible; a person exposed to its full influence drops senseless, and rarely recovers its approach is known by a peculiar smell, on perceiving which, every living being runs to seek shelter. It is conjectured that the hydrophobia, which attacks dogs, wolves, and jackals, is caused by the simoom.

The season of rains, called in India the south-west monsoon, is felt in the eastern parts of Afghanistan, though not so violently as in India. It commences about the end of July, when the earth, which has been parched by the summer heat, resumes the appearance of spring with miraculous rapidity; at other times there is little rain, fogs and clouds are rare, and the air is usually dry. The average heat is less than in India; and the difference of temperature between day and night, and winter and summer, is much greater than either in India or England. The climate generally is healthy; the most common diseases are fevers, colds, and ophthalmia; and occasionally the small-pox is very fatal, in spite of inoculation, which has been long practised.

The mineral resources of Afghanistan are not much developed. No gold is found, with the exception of some grains in the torrents near the great northern mountains, and but little silver; mines of lead and iron are wrought, and fine rock salt is dug in the north-west. Whole cliffs of lapis lazuli exist in the mountains.

The western country is mostly high and bleak, much fitter for pasturage than agriculture, and is generally inhabited by shepherds who dwell in tents.

The animals of Afghanistan are like those of India; the lion is small and very rare. Tigers and leopards are found in the eastern parts, and hyænas, jackals, wolves, and foxes, everywhere. There are many bears, but they rarely descend into the plains. Horses are common, and in some parts very fine. Asses are much used in the labours of agriculture; but the chief beast of burden is the camel, the same long-legged animal used in India. The stout short camel, with two humps, is sometimes used, but more rarely. The principal stock of the rural population consists of sheep; a fine handsome animal, with tails of solid fat a foot broad. Goats, dogs, and cats, with long silky hair, are all in abundance.

Two or three sorts of eagles frequent the mountains, and several species of falcons, many of which are used in hawking, to which the Afghans are much addicted; their game is chiefly the same as in Europe: wild ducks, swans, quails, partridges, &c. &c.

The trees are generally the same as in Europe, and our finest fruits grow wild in the plains and valleys. The products of agriculture are wheat, barley, rice, Indian corn, millet, pulse, tobacco, &c., &c., carrots, turnips, cabbages, and garden vegetables in general. In the eastern parts, dates, ginger, turmeric, cotton, and sugar-cane, are cultivated in favourable situations.

In a government so unsettled as that of Afghanistan, the political divisions are necessarily variable. When the British embassy was at Peshawer, in 1809, the kingdom was divided into twenty-seven provinces or governments, the eighteen most important of which were superintended by resident hakims, who collected the revenue and commanded the troops. Many of these provinces, as Sind, Mooltan, Cashmere, &c. &c., are now quite independent; others, as Balkh, Herat, Seestan, &c., though nominally connected with the government, do not come within our object, which is only to describe Afghanistan, and not its dependencies. On crossing the Indus at Attock, the first province is Peshawer, in the valley of the Cabul river; the provinces of Jellalabad, Lughmaun, and Cabul, follow in regular succession westward along the same river, and at its sources is the united province of Bamian and Ghorebund. All these provinces lie immediately south of the great chain of the Hindoo Koosh, and though small, they are the most important of the kingdom, by their fertility and population. South of Cabul is Ghizni; Candahar lies considerably to the southwest of Ghizni; and Furrah much farther to the west, within the country of Khorassan. In all these the chief town has the same name with the province.

The remaining nine divisions are composed of countries almost wholly inhabited by Afghans, or pastoral tribes, where there are few towns. There is a governor appointed to each, whose authority is little more than nominal, as he never resides, but generally leaves the government wholly to the heads of tribes, subject, perhaps, to occasional control. These nine provinces comprise almost the whole surface of the kingdom; the others, though politically most important, being only small populous districts, chiefly inhabited by people of foreign origin, and intersecting the nine large divisions. The most important of these divisions are the tribes of Damaun, inhabiting the countries between the right bank of the Indus and the Soliman mountains; the Ghiljies, stretching over the centre of the country, from the neighbourhood of Candahar to the mountains of the north, and inclosing the provinces of Ghizni, Cabul, Lughmaun, and Jellalabad; the Eimauks form a province in the west of the Paropamisan mountains; and the eastern part of the same range is the province of the Hazaurehs. The remaining include all the Afghan tribes subject to the government of the king.

The capital is Cabul, the chief city of the province of the same name, which forms the eastern half of Afghanistan. Cabul is situate on the Cabul, in a large well-watered plain, filled with villages. The town is surrounded on three sides by low hills, on one of which, to the north, is the king's palace. The tomb of the Emperor Baber, on a hill near the city, surrounded by large beds of flowers, commands a noble prospect. The town is not large, but is handsome and compact; and the houses are mostly built of wood, to avoid the consequences of the frequent earthquakes. Beautiful gardens surround the town, which is celebrated for its fine climate, though the proximity of the mountains causes great varieties of temperature. N. lat. 31° 10′, E. long. 71° 43.′

Peshawer is situated in a plain nearly circular, about thirty-five miles in diameter, and surrounded by mountains on every side, except a slip of fifteen miles width to the east. The plain is well watered and always green; it is in high cultivation, and produces plums, peaches, apples, pears, pomegranates, and mulberries, with a few dates. The city is about five miles round, and contains 100,000 inhabitants. The houses are built of brick, about three stories high: the streets are narrow and slippery, but are paved, and have a gutter in the centre. Part of the town is flooded during the spring rains, which make it then an unwholesome residence.

Ghizni was once the capital of an empire reaching from the Tigris to the Ganges, and was adorned with the most splendid buildings in Asia; but it is now reduced to about 1500 mean dwellings. Some remains of its ancient grandeur are still to be seen in its neighbourhood; among the rest the tomb of Sultan Mahmood, the conqueror of India. This structure is about three miles from the city, and is spacious, though not magnificent, and covered with a cupola. The doors, which are very large, are of sandal-wood, and said to have been brought as a trophy from the temple of Somnaut in Guzerat. On a tombstone of white marble lies the mace of Mahmood, of such a weight that few men can wield it. Mohammedan priests are still maintained, who constantly read the Koran over the grave. Ghizni is in 30° 11′ N. lat. and 68° 57′ E. long.

Candahar is on the site of an ancient city, conjectured to have been one of those founded by Alexander the Great. The present city is quite modern, and was founded by Ahmed Shah in 1754. That king made it the capital of his dominions; but on the accession of Timour Shah in 1774, the seat of government was removed to Cabul. Candahar is large and populous, supposed to contain 100,000 inhabitants. Its form is oblong, and its plan perfectly regular; four streets meet in the centre, in a circular place, fifty yards in diameter, surmounted by a dome. This is called the Chaursoo (sharshee), and is a public-market place, surrounded by shops; the four principal streets are fifty yards in width, are lined with shops, and extend to the gates of the city. The smaller streets are narrow, but straight, and all cross at right angles. The town is well watered by canals from the Urghundaub, a tributary of the Helmund; and a small stream runs through almost every street. The tomb of Ahmed Shah, covered by a gilt cupola, stands near the king's palace, and is held as a sacred asylum, the king himself not daring to take a criminal from it. Candahar, unlike any other city, is chiefly inhabited by Afghans, who have conformed externally to the habits of Persians. Its situation is in 32° 10′ N. lat., 66° 30′ E. long.

All the large towns are inhabited chiefly by Persians and Indians; an Afghan never keeps a shop or exercises any trade. The only Afghans found in towns are the officers of government and their followers, soldiers, priests and, perhaps, a few labourers. The houses of the rich are inclosed by high walls, and contain three or four courts, with gardens and fountains. Each court contains a building, with several small apartments, and three or four large halls, reaching to the roof, supported by wooden pillars, carved and painted, The apartments open on the halls, and are fitted up with paintings and looking-glasses. One room at least has glazed windows, and several have fire-places. The doors are carved, and covered in winter with velvet or brocade. The floors are covered with handsome carpets, and thick felt seats go all round the room, close to the wall, covered with silk or velvét. The houses of the common people are of one story, and usually of a single room, about twenty feet long by twelve broad: they have little ornament and scarcely any furniture. Neither tables nor chairs are used; their place is supplied by coarse woollen carpets and thick felt cushions.

The Afghans, who compose little more than a third of the dwellers in Afghanistan, are of moderate stature, but remarkably hardy and athletic. Their high cheek bones and prominent noses distinguish them essentially from the Tartars, with whom some persons have confounded them. Their complexions are various; men as fair as Europeans being found in the same places with others dark as Indians. The western tribes are fairer than those of the east. Their hair and beard are mostly black; occasionally brown or red. The usual dress is a sort of frock, reaching below the knee, and loose dark cotton trowsers. The head is covered with a low flat-sided cap of black silk, with a coloured or brocaded top. They wear half boots, laced in front. The dress of the western tribes resembles that of Persia, and the people of the east imitate their neighbours of India.

The manners of the Afghans are frank and open; they pay little respect to rank, but show great reverence for old age. They are very sociable, and give frequent dinner parties, which are accompanied by singing, dancing, and music. Any game of chance or skill, however childish, that may lead to a dinner, is played with great zest; marbles, prison-bars, hunt-the-slipper, hopping, &c. &c. and the loser treats his opponent. They are also fond of sitting in a circle, conversing, or listening to story-tellers. The people of the east notice the attachment of the Afghans to truth, in which they are much superior to their neighbours of India and Persia, though Europeans will not rank them very high in that respect. They are filled with family pride, and fond of recounting long genealogies, scarcely allowing a man to be a genuine Afghan who cannot prove six descents. They are very jealous of attentions paid to others, and can be more easily wrought upon by kindness than threats.

Hospitality is the great characteristic of Afghans; it is with them a point of honour; and a greater affront cannot be given to an Afghan than by inviting his guest to another dwelling. A man may travel without money from one end of the country to the other, and the bitterest enemy is safe if he claim the protection of hospitality. A person who has a favour to ask of any person goes to his house, and refuses to sit down or partake of food until the boon be granted. This custom is called *nannawatee*, and it brings disgrace on a man to reject a petition under such circumstances.

Another resemblance to the Arabs of the desert, so celebrated for their hospitality, is the practice of robbery by the ruder tribes of Afghans. A traveller passing through certain districts must expect to be plundered, if not under strong protection, while a stranger coming to settle amidst them is perfectly safe. These robberies, however, are never accompanied by murder, and where the government is powerful the traveller is safe.

The good qualities of the Afghans have been summed up, by stating that they are faithful, hospitable, brave, frugal, laborious, and prudent. Their bad qualities are revenge, avarice, envy, rapacity, and obstinacy.

Among the western tribes, the pastoral character is much retained; many tribes live entirely in black coarse woollen tents, and migrate with their flocks from place to place, as convenience directs. But although the larger extent of ground is occupied by the dwellers in tents, the dwellers in houses are the more numerous body. Agriculture is very generally on the increase: many parts of Afghanistan are highly cultivated, and the most remote regions are not without marks of human industry.

The religion of the Afghans is the Mohammedan of the Sunite sect, though accompanied with less bigotry than usual. Hindoos and Christians live peaceably and respected among them: and even Persians, who are of the dissenting Shiite sect, and, therefore, more abominated by the orthodox than even infidels, hold high official stations among them, upon the simple condition of abstaining from curses on the three first caliphs, the denial of whose right to the commandership over the Faithful forms the chief reason of their dissent.

Social intercourse with women is less restrained than among other Mohammedans, though in towns the females of the upper ranks live secluded, and never go out without a covering from head to foot. In the country, women go out unveiled. in the lower ranks, they do the work of the house, and in some of the inferior tribes assist the men in the labours of agriculture. Their marriage ceremonies are like those of the Persians.

The language of the Afghans is called Pushtoo; half the words of the language are Persian, but almost all the particles and verbs are from some unknown root. Many words have been said to be identical with those of the Zend and Pehlevi, the ancient languages of Persia, and with those of the Sanscrit, the ancient language of India; and this in cases where the words are quite obsolete in the modern dialects of these countries. This, however, is doubted by some. The structure of the Pushtoo refutes the old opinion that the Afghans are descended from the Jews. The sound of the language is rough, but not disagreeable to persons accustomed to oriental tongues. They use the Arabic alphabet, with points over and under certain letters to represent sounds unknown to Arabic. The only original Pushtoo authors are poets; their compositions are chiefly lyrics, of a spirited and bold cast, breathing a strong attachment to liberty. No Pushtoo authors are above a century and a half old; but Persian works are as familiar to the educated Afghans as their own, and the Persian language is that chiefly used in composition.

The education of the Afghans is not neglected; every village has its school, generally kept by a priest, and almost every boy attends it. In some tribes, boys are sent to a distant village, where they live in the mosque, and are under the sole guidance of their schoolmaster. The most celebrated university is at Peshawer.

Many females are acquainted with Persian literature, and almost all those of a certain rank can read; but writing is not commonly taught there.

The whole nation is divided into tribes, which continue much unmixed, each under its own peculiar government, with little interference from the royal power. The internal government of the tribes is republican; they are divided into separate clans, and each clan has its chief or khan, chosen from the oldest family. The khans administer justice in most cases, but rarely without the concurrence of a council of the heads of families. The clans are eminently exclusive, and are often at feud with each other. They appear to be little attached to their chiefs, but very strongly to their tribe. They are very jealous of interference, and their republican spirit has preserved the country from degenerating into the ordinary oriental despotism. The reply made to an English traveller, who expatiated on the freedom from alarm, blood, and discord, which must ensue from a more steady government, was 'We are content with discord, we are content with alarms, we are content with blood, but we will never be content with a master.'

The land is cultivated by tenants, who pay rent, or by persons who give half the produce to the landlord, receiving seed and instruments of agriculture from him. Many small proprietors cultivate their own land by the aid of hired labourers, or slaves attached to the soil.

The trade of Afghanistan is small, and only carried on by caravans. The most important trade is with India, whence they import cottons, muslins, ivory, indigo, tin, wax, sugar, and spices. The exports are horses, furs, shawls, tobacco, and fruits.

The government is a limited monarchy, The king may make peace and war; he has the control of the revenue, and appoints to such official situations as are not hereditary. He cannot increase the revenue, which arises from a fixed assessment on lands, and amounts to about 2,000,000*l.* sterling. He is, in fact, the Khan of the Duranees, the principal tribe; and although his power has infringed upon the republican institutions of his own clan, his right over other tribes extends only to the levying troops, and the collection of revenue. Over those of his subjects who are not Afghans, his power is less limited, but it is rarely exercised with severity. The Duranee lords control the king, who can rarely act without their concurrence. The crown is hereditary in the family, but elective as to the person.

The administration of justice is corrupt, as in every other Asiatic government. A cadi is appointed to every large town, before whom causes are brought, and whose awards are rarely disobeyed: death is very rarely inflicted, and the horrid mutilations so common in Persia are unknown. The cadi never interferes unless called upon; most cases are decided by the heads of tribes, as the Afghans dislike all application to law; and even a murder, if in retaliation, is rarely inquired into. The police generally is defective; watchmen are appointed in all large towns, paid by the inhabitants of the different wards. Parties are stationed in dangerous places for the protection of travellers, who find, however, the purchase of security from the clans a more efficient guard.

The military may be about thirty thousand. One-third of these are Gholams, or military adventurers, who enlist for life; about ten thousand are furnished by land-owners at a stated rate; and a large contingent is supplied by the Duranee clan, as the condition on which they hold their lands. Their soldiers are chiefly horsemen, and their arms are swords and matchlocks.

The history of the Afghans cannot be traced to a remote period. In the ninth century they were possessed of the north-eastern part of their present empire, and at the close of the tenth a chief of Khorassan conquered the country, and made Ghizni his metropolis. For two hundred years his family governed the empire; but although the plains were conquered, the Afghans maintained their independence in the mountains. At last, under the conduct of Mohammed of Ghore, a descendant of their ancient princes, they dethroned the king of Ghizni, and burned his capital, A.D. 1159. The new dynasty extended the empire from the Tigris to the Ganges; but while making conquests abroad, their own territories became the prey of a stranger; and while Afghans were seated on the throne of India, Jenghis Khan and his descendants ruled in Afghanistan. The Mongol dynasty reigned over the plains, and the Afghans dwelt in the mountains. After the death of Tamerlane, in 1405, the country appears to have been independent for a century. In 1506, the Emperor Baber, a descendant of Tamerlane, conquered Cabul, and made it the seat of empire: the plains of Afghanistan were then divided between India and Persia, but the Afghans still preserved their precarious independence. At the death of Aurungzeb, in 1707, when the Mogul empire lost its power, the Afghan tribe of Ghiljie grew strong, conquered Persia, and founded an empire of vast extent, but little duration. This dynasty was overthrown by Nadir Shah of Persia, who conquered the Afghans, and annexed their country to his empire. At his death in 1747, Ahmed Shah, an officer of an Afghan troop, in the service of Persia, fought his way back to his own country, and founded the present monarchy. From that time to the death of Timour Shah in 1793, the empire maintained its splendour, but on that event, a civil war broke out between the sons of the deceased king. Four brothers in succession gained the throne, the Persians invaded Khorassan, and several dependent rulers threw off their allegiance. The monarchy is still in the same unsettled state, and is, in fact, little more than a name; but the peculiar organization of the tribes obviates the evils which elsewhere result from civil war. The people take but little part in it, considering it merely a quarrel of kings, to whom they have not much attachment, and content themselves with defending their mountains, where they are rarely molested: and although the cities and great roads occasionally suffer from the disputes of contending factions, and the plunder of marauding armies, the country has lost few of its resources, and none of its enjoyments.

The chief authority for Afghanistan is Elphinstone's *Cabul*. The reader may also consult Foster, Rennell, and the Asiatic Researches: for the sixteenth century, see the *Ayin-i Akbari* of Abul Fazl. See also Hamilton's *History of the Rohilla Afghans*, in the country EAST of the Ganges, London, 1787; and Bernhard Dorn's *History of the Afghans*, part i., London, 1829.

AFIOUM, or OFIUM KARA HISSAR, (that is, the Black Castle of Opium,) is, according to D'Anville, situated on the spot where formerly Apameia Kibotos stood. At Afioum are remains of temples and palaces decorated with black marble. The site of Afioum is fixed in 38° 45′ N. lat. 30° 46′ E. long.

The original name of Apameia was Celænæ, under which denomination it is described by Xenophon, Herodotus, and Arrian. Antiochus Soter gave it the name of Apameia, as Strabo informs us, who also describes the place. Notwithstanding all this, it is not *yet* certain whether Afioum Kara Hissar, or some other town, represents Apameia; and this fact, when we consider the minuteness of the ancient descriptions, is one among other proofs how little we know of the interior of Asia Minor. Taking into account that Apameia was the centre of a great commerce, as Kara Hissar now is, and combining this with the resemblance of name and Pococke's description of the citadel, as compared with Arrian's account of Celænæ, it seems most probable that Afioum is Apameia. [But see Rennell's *Geography of Western Asia*, ii. p. 144.]

The following extract is taken from Pococke's *Travels*, whose opinion as to the ancient site differs from ours: 'Carahissar is distinguished among the Turks by the name of Aphioum Carahissar, on account of the great quantities of *ophioum*, or opium, which is made here. I had great satisfaction in finding, by an inscription, that Carahissar is the ancient Prynesia of Ptolemy, because it is of great use in making conjectures as to the situation of other places mentioned by that author. It is situated at the foot of the mountains round a very high rock, about half a mile in circumference, on the top of which they have built a fortress. The work is a sort of bastard, brown granite; it is of a black hue, from which the town is called Carahissar (the Black Castle); it is so very steep that it would be impregnable if supplied with provisions and water, and it seems to be half a quarter of a mile in perpendicular height. The town is near three miles in circumference, and it is a great thoroughfare, has much trade, and good shops provided with all sorts of things, being in a plentiful country, and many caravans pass through it. It is the residence of a pasha. There are in the city ten mosques; one of them is a noble building with a portico before it, the whole being covered with domes. There are neither Greeks nor Jews in the city, but about fifty Armenian families, besides several merchants and tradesmen, who stay here part of the year as they do in other towns, living in khans; they have two churches, and of late they have had a bishop, whom they call metropolitan. In the country between this and Smyrna they make most of the Turkey carpets,' &c.

The population of this town is stated at 50,000 or 60,000. It is of some importance for its fabrics of wool, tapestry, fire-arms, and sabres. But the chief article of commerce is the opium cultivated in the neighbourhood. Afioum is also the rendezvous of the caravans from Constantinople and Smyrna, which from this place proceed further into the interior.

AFRICA. In treating of one of the great divisions of our globe, it is necessary to say a few words on the plan which we have adopted as most suitable to a work of this kind. If we were to attempt a complete geographical description of Africa, it would have little value from being compressed within such narrow limits as we should be compelled to assign to it. Twenty numbers in succession would not be sufficient to enable us to give a satisfactory view of this continent, if we were to enter into details. We have, therefore, determined to present our readers with such a sketch or outline, as will show *generally* the present state of our knowledge with respect to Africa; and by turning to the separate articles, such as Alexandria, Cape of Good Hope, Egypt, &c., they will find under each head of city or country, the latest and best information that we have been able to collect. The following are the heads that we propose briefly to treat here:—

I. Africa as known to the Greeks and Romans.
II. Circumnavigation by the Portuguese, and their settlements. French and English discovery.
III. Short notice of what coasts have been surveyed.
IV. General remarks on the figure of Africa, its surface, mountain chains, plateaus, rivers, mineral productions, &c.
V. Varieties of the human race in Africa.
VI. Zoology of Africa.
VII. Botany of ditto.
VIII. Chief divisions, and foreign settlements.

I. The name *Africa*, which is no doubt of native origin, was probably first introduced into Europe by the Romans, who gave this appellation to one of their African provinces, which comprehended the city of Carthage. Africa was, therefore, properly the name of a limited district, which has since been extended to the whole of this vast continent: the same thing has constantly taken place in modern times, and the name of a remote spot or tribe has been magnified into that of a country or a nation. But the real name for this continent, both in the Greek and Roman writers, is Libya. Herodotus, the earliest extant Greek author who has transmitted to us any information about Africa, has given a proof of his limited acquaintance with it by the very simple division which he makes of its inhabitants. All the native tribes in the northern part he calls by the general name of Libyans, and those in the south Ethiopians. Egypt, according to his system, hardly belongs to Africa, but lies like an isolated slip between the two adjacent continents. He was evidently puzzled about assigning a boundary to Asia and Africa, and he is often led, almost unintentionally, though with perfect correctness, to give the name of Arabia to the part immediately *east* of the Delta and the Nile. Herodotus asserts that Africa is surrounded with water, except at the narrow neck now called the Isthmus of Suez; and one reason for his belief was apparently the story of Africa being circumnavigated by the Phœnicians in the reign of Pharaoh Necho, (as he is called in Kings ii. chap. 23,) King of Egypt, and between the years B.C. 610 and 594. The circumstances of the voyage as reported by Herodotus are very meagre, and when faithfully presented will enable the reader to form his own opinion of the probability of the voyage having been made. Nechos, King of Egypt, (Herod. iv. 42,) despatched some Phœnicians in vessels, with instructions to sail round Libya and through the pillars of Hercules (straits of Gibraltar) into the northern (Mediterranean) sea, and so to return to Egypt. The Phœnicians set out from the Red Sea, and navigated the southern ocean. When the autumn came on, it was their practice to land on whatever part of the coast they happened to be, to sow the ground and wait for the harvest. After reaping it, they would again put to sea; and thus after two years had elapsed, in the third they passed through the pillars of Hercules and arrived at Egypt. And they said, but for my part I do not believe the assertion, though others may, that in their voyage round Libya they had the sun on their right hand.'

This Phœnician voyage is the only direct statement as to the ancient *circumnavigation* of Africa that deserves a particular examination, and the best critics are divided in opinion upon it. We do not believe the circumnavigation was effected, and for the following reasons. Herodotus visited Egypt about 150 years after the event, a time long enough to allow the original story (for we believe the whole to be founded on *some* facts) to have become much perverted from the truth. The phænomenon of the sun being to the right hand, or to the *north* of the voyagers, would be observed during part of the year, if they never went beyond the straits of Bab el Mandeb. The time allowed for the circumnavigation is too short; and the difficulty of sowing and reaping on an unknown coast, to say nothing of the opposition which the natives might offer, and the dangers of the voyage itself, are serious objections: and, finally, the notion which Herodotus had, and which was long the prevailing one, that Africa did not extend so far south as the real equator, is decisive against the truth of the voyage. If it ever had been made, it is impossible that so erroneous a notion as to the southern extent of Africa would not have been corrected. We refer the reader to Mannert's *Geography of the Greeks and Romans*, vol. i., for further examination of this question, and other supposed circumnavigations. Compare also Gosselin, *Géographie des Grecs Analysée*, p. 108, &c.

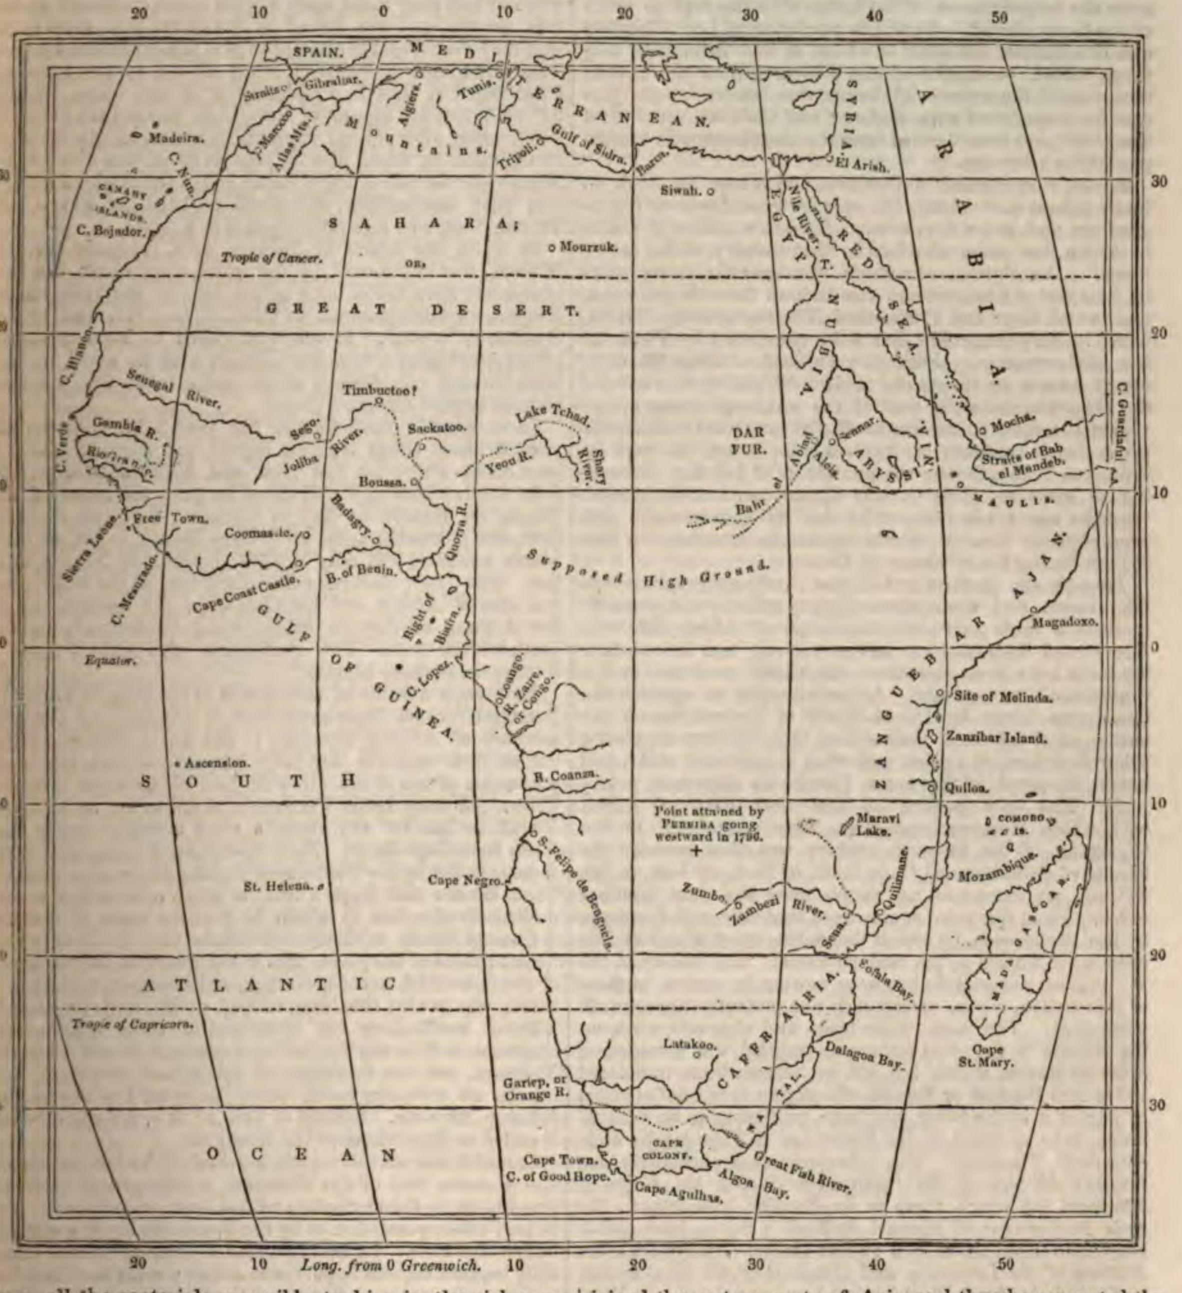
Another ancient voyage is somewhat better authenticated. Hanno, one of the ruling men of Carthage, or king, as he is termed, sailed from that city through the straits of Gibraltar, to establish some colonies along the Atlantic coast of the present empire of Marocco. He took with him a large fleet, and 30,000 settlers, whom he left at various places, and then bent his course further south. He passed a river with crocodiles and river-horses in it, and it has, therefore, been concluded that he went at least beyond the Senegal; but it is not easy to fix with any precision the extent of the voyage, though it must have been considerably to the south of the Senegal, according to the statement of the voyager. Yet it could hardly be farther than the Sierra Leone coast, and it *may* have extended not so far. Major Rennell, whose opinion is entitled to the greatest respect, gives this extent to the voyage; but he also advocates the truth of the Phœnician circumnavigation of Africa, which makes us somewhat more scrupulous than we otherwise should be in receiving his interpretation of the voyage of Hanno. M. Gosselin, who is more sceptical than the English geographer, does not carry Hanno further than the latitude of the Canaries. Polybius, the Greek historian, was sent by Scipio Æmilianus to explore the same coast, (*Pliny*, v. 1.) but it is impossible to state how far he went, from so defective an extract as that contained in Pliny. The time at which this voyage of Hanno was made is uncertain, though we are inclined to place it before B.C. 500. Herodotus, however, who lived after this date, says nothing about it; yet this is not so strong an objection as it might appear at first, since Herodotus, consistently with the plan of his history, never mentions the Carthaginians, except incidentally; though it is certain that he knew much more about them than he has told us. The voyage of Hanno, which was originally written in the Punic language, has come down to us in a Greek translation, though probably mutilated; and may be seen in Hudson's *Collection of the Minor Greek Geographers*, vol. i.

When the Greeks were settled in Egypt under Ptolemy, the son of Lagus, one of Alexander's captains, (B.C. 323,) they necessarily became better acquainted with the Red Sea and the course of the Nile; and from this epoch we may date the extension of that trade with India, by which the products of the great Asiatic peninsula and of Ceylon were more generally diffused over the western world. This trade existed in great vigour under the Roman emperors, and we have an example of it as late as the sixth century of our æra, in the work of COSMAS. Indeed the origin of the trade between the Indian peninsula and Arabia, and Eastern Africa, belongs to a period anterior to any history; and this commerce has probably never been totally interrupted at any time since its commencement.

One of the most curious documents with respect to ancient navigation on the east coast of Africa, is contained in the Periplus of the Erythrean Sea, which goes under the name of Arrian. This work, which was probably compiled from various log-books and journals, may be assigned to about the time of Pliny the elder, or perhaps to an earlier period. It has been illustrated, generally in a very satisfactory way, by Dr. Vincent. The Periplus contains much valuable information on the Red Sea, and also a description of the coasts of Arabia, Persia, the western coast of India, and the eastern coast of Africa. The extreme south point mentioned on the African coast is Rhapta, which Dr. Vincent thinks to be identical with Quiloa. It would seem as if this work was intended for the use of merchants, as the compiler has carefully mentioned the articles of export at each place of importance, and also has informed his readers what kind of commodities would meet with the readiest sale.

From the tables of Ptolemy, the Greek geographer, it appears that the coast of western Africa was known, probably though the navigation of the Carthaginians and the Romans, as far as to 11° north of the line. It is a curious question whether the ancient geographers were acquainted with the countries south of the Great Desert, and with the upper part of the river Quorra, commonly called the Niger. Herodotus tells a story, which he heard from some people of Cyrene, of some young men of the Nasamones, a tribe near the present gulf of Sidra, crossing the desert in a westerly direction, and coming to a great river which ran towards the rising sun, and had crocodiles in it, and black men living on its banks. It is very hard to give implicit credit to all the circumstances of this narrative; and yet it deserves great respect, because there are real facts corresponding to the description. The nature of the narrative, however, is such as to render it impossible to demonstrate satisfactorily either the truth or falsehood of this early discovery. But there are other considerations which must not be omitted in forming an opinion as to the knowledge which the ancients had of central Africa. It can hardly be imagined that the powerful state of Carthage, which employed so many elephants in war, and carried on so extensive a commerce, could be altogether ignorant of the countries south of the Great Desert. The elephant, we have no reason to believe, was ever an inhabitant of the Atlas regions, except so far as it was domesticated among the Carthaginians, and therefore must have been brought to Carthage from central Africa; while the articles of commerce, which the interior now furnishes to the coast of Tripoli, were commodities in which the Carthaginians used to deal, such as slaves, ivory, gold, &c. As to any objections raised to this statement about the elephant, from Pliny's assertion that it was found in Mauritania, we well know how to estimate that writer's evidence on such points; it is indeed of very little value, even though supported by Strabo, and the Periplus of Hanno. Seleucus Nicator kept a stud of 500 elephants

(Strabo, xvi. p. 752) at Apameia, and he had to bring them a greater distance than the Carthaginians would have, if they procured them from central Africa. The Carthaginians themselves had extensive elephant stables and grounds near the city. (Strabo, *Casaub.* 832.) When the Romans became masters of North Africa, we might expect to find them attempting, according to their usual policy, to enlarge their empire or their influence to the south; and we have, in fact, in Pliny, a distinct account of Suetonius Paullinus, A.D. 41, crossing the great mountains of Atlas, and going some distance south; and, in Ptolemy, we have an account of a Roman officer, Maternus, who set out from the neighbourhood of Tripoli, and went a four months' march in a southern direction. This route must have brought him into the latitude of Timbuctoo, and into the neighbourhood of the Tchad; and if the story is true, the great river, now commonly called the Niger, might have been thus known to the Romans. In examining the tables of Ptolemy, in which the positions of places are laid down according to their latitude and longitude, we find no reason to doubt their general accuracy along the western coast as far as N. lat. 11°. He has also given the position of a number of places in the interior, on a river which he calls Nigir; and the direction thus assigned to the river will come as near the truth as we could expect it to be, even if we knew Ptolemy's tables to be constructed upon real observation, such as was practicable at that time. A complete discussion of this question is given in the second Number of the Journal of the Royal Geographical Society of London, by Col. Leake, who is in favour of the opinion that the Joliba of Park, commonly called the Niger, was known to the Romans, and to Ptolemy, who constructed his tables from all the materials accessible to him in the rich commercial city of Alexandria, where he lived.



The Fortunate Islands (now the Canaries) were known to Ptolemy, and he reckons all his eastward distances or longitudes from them, or from some one point in them; for he does not appear to have known anything accurate as to the relative position of these islands. And as coasting voyages had considerably extended the knowledge of the east coast of Africa, without however showing any termination of the land, Ptolemy concluded that the southern parts of Africa joined the eastern parts of Asia, and thus he converted the Indian Ocean into an inland sea.

The Greek and Roman writers mention the following remarkable African animals with which they were acquainted:—the crocodile and the hippopotamus, both in the Nile and the rivers of western Africa; the giraffe, or camelopard; the elephant; the two-horned rhinoceros; and the ostrich. With the exception of the hippopotamus, all these animals were at different times seen in the Roman capital. The camel is not mentioned as being found in

Africa by any ancient writer, we believe, except Herodotus (vii. 69, 86, iii. 9), and it is therefore concluded that it was introduced into this continent by the Arabs: this opinion will be noticed under the head of AFRICAN ZOOLOGY.

On the occupation of Egypt by the Arabs in the seventh century of our æra, and the spreading of this conquering people through Africa, the regions south of the Sahara soon became known to them, and felt the influence of their religion and their arms. The Moors have now for centuries been in the habit of sending caravans across the Desert to Sudan, as the country south of the Sahara is often called, and they accordingly possessed some knowledge of these central regions long before they were visited by any Europeans. But the accounts of the Arabic writers cannot be said to add much to the information contained in the Greek and Roman writers, if we admit that the evidence is satisfactory as to the acquaintance of the latter with the regions south of the Great Desert. With the exception of Leo Africanus and Ibn Batuta, the latter of whom, in the fourteenth century, visited the banks of the Joliba, it does not appear that any of the extant Mohammedan writers were personally acquainted with Sudan; and their accounts must therefore have been derived from the merchants who accompanied the caravans.

Edrisi, who studied in Cordova, and wrote his book in Sicily (about A. D. 1153), can only be considered as a geographer, and not a discoverer. He was a native of Ceuta in Africa, but never travelled in that country, as far as we know. Ibn Batuta, who was a wanderer for thirty years in Asia and Africa, crossed the Sahara from Segelmessa, and visited Sego and Timbuctoo. The work of Ibn Batuta, which is very imperfect, has been translated by Professor Lee of Cambridge. John Leo, an Arab of Granada, commonly known by the name of Leo Africanus, also crossed the Desert in the early part of the sixteenth century, and visited the cities on the banks of that great river which has given rise to so many conjectures. Leo wrote his work on Africa at Rome, during the pontificate of Leo X. According to some accounts, it was already written in Arabic when he was taken prisoner by the Christian corsairs and presented to Leo, at whose request he translated it into Italian during his residence at Rome.

Though the descriptions of the Arab geographers are often vague and unsatisfactory, they still show in some directions a more extensive knowledge of Africa than the Greeks and Romans have left on record; and indeed their accounts have been sometimes singularly confirmed by the inquiries of our own age. As an example, we mention the description given by Ibn-el-Wardi of the natives on the east coast of Africa, of their selling their children for slaves, filing their teeth to a point, and other peculiarities still found among the people of that coast. [See Salt's *Abyssinia*, p. 56.]

II. The only portion of the west coast of Africa with which European navigators were acquainted at the beginning of the fifteenth century was that between the Straits of Gibraltar and Cape Nam, or Nun, or Non, in lat. 28° 40′, an extent of not much more than six hundred miles. From this point commenced that career of discovery, by the Portuguese, by which the entire coast of Africa has been made known to the modern world. The history of the Portuguese navigations has been written by various authors of that nation, whose accounts do not perfectly agree in all particulars. The most voluminous and elaborate work on the subject is the *Asia* (otherwise entitled the *Decades*) of John de Barros, which has not, we believe, been translated either into English or French, although a very brief abstract of part of it in the latter language, professing to be a translation, is to be found in the Collection of Voyages by Melchisedech Thevenot. The other principal authorities are Osorio's *History of the Portuguese during the Reign of Emanuel* (of which there is an English translation), the *Asia Portuguesa* of Manuel de Faria y Sousa (also translated into English, as well as into Italian and French), the *History of the Discovery and Conquest of the East Indies*, by Castañeda, (part of which has been translated into English,) and the *Tratados* of Antonio Galvam, of which there is an English version in Hakluyt.

The original promoter and for a long time the director of these expeditions was Prince Henry, a younger son of John I., commonly called the Bastard, King of Portugal, and of his wife Philippa, daughter of John of Gaunt, and sister to Henry IV. of England. The curiosity of Prince Henry had been first excited about the unexplored parts of Africa, by the accounts of the country of Guinea, and the kingdoms in its neighbourhood, which he had received from the Moors. Animated by the desire to acquire further information respecting these mysterious regions, he took up his abode, in his twenty-first year, at Terçanabal, in the Bay of Sagres, not far from Cape St. Vincent, the point of his native country nearest to the coast of Africa, and prepared to devote the remainder of his life, as in fact he did, to the task of achieving the circumnavigation of that vast continent.

Before this, however, a single ship appears to have been sent out, in the year 1412, by King John, which had doubled Cape Nun, although other accounts say that this exploit did not take place till 1415, when it was accomplished by two small vessels dispatched by the Prince. The navigators advanced for about sixty leagues farther along the coast, which was found continually to trend to the south-west; when at last they came upon a point which projected so far into the sea, and was lashed by the waves with such fury, that they were afraid to attempt to pass it, and returned home. This formidable promontory, since known by the name of Cape Bojador, that is, Projecting or Round Cape, (in lat. 26° 20′,) does not appear to have been doubled till 1432, or 1433, when, after several attempts, it was at length doubled by Gilianez, by whom also its present name was given to it. Meanwhile the isle of Porto Santo, one of the Madeira group, had been accidentally discovered in 1418, by Zarco and Tristan Vaz, who had come upon it in a storm.

In 1419, the island of Madeira itself (properly written Madera) was discovered by the same navigators; but this island had been visited long before, both by the unfortunate English captain, Macham or Machin, in 1344, and by the Spaniards in 1421. It was first called St. Laurence, and afterwards Madera, from the Spanish word for *wood*, having been covered with forests, which, being set on fire, are said to have burned for seven years.

In a second expedition, in the year 1434, Gilianez advanced about thirty leagues beyond this cape, and landed on a coast, where he saw men and flocks, and to which, from a fish which he found there, he gave the name of the Angra de Ruivos, or Bay of Gurnets. In 1440, Antonio Gonzalez proceeded as far as to Cape Blanco, in lat. 20° 47′, which, however, was only in 1443 doubled by Nunno Tristan. The latter navigator also discovered at the same time the isles of Adeget and las Garças (or the hawks), two of the Arguim or Arguin group, lying immediately to the south of the cape. The Portuguese afterwards formed a settlement in these islands.

In 1444, a number of individuals in the town of Lagos in Portugal formed themselves into a company for the prosecution of African discovery; and an expedition, fitted out at their expense the same year, discovered and took possession of two of the other Arguin isles, named Nar and Tider. In 1446, Dinis Fernandez sailed as far as to Cape Verde, in lat. 14° 48′, along a coast running nearly due south from Cape Blanc. Next year, Lancelot (or Lançarote, as he is called by the Portuguese writers) discovered, between Cape Blanco and Cape Verde, a great river called by the natives Ovedec, but to which he gave the name of Sanagà or Canagà, being, say Barros and Sousa, that of a Moor whom he put ashore at the place. But it was doubtless the name not of the individual, but of his nation, which he gave to the river; which was really, therefore, named, as Rennell, apparently without recollecting the statement of these writers, has conjectured, from the Senhaji or Assanhaji, in our maps the Zenhaga, and the Sanhagæ of Edrisi and Abulfeda, who inhabit its northern bank.—(See *Geography of Herodotus*, vol. ii. p. 28, note. Edition of 1830.) It is the same which is called in English maps the Senegal.

Lancelot also on this voyage touched at the isles of Palma and Gomera, two of the Canaries, which group, however, was known to the ancients, and had been re-discovered and in part taken possession of by the Spaniards about a century before this time. In 1447, Nunno Tristan advanced about sixty leagues beyond Cape Verde, along a coast now trending to the south-east, and discovered the Rio Grande, in sailing up which he was attacked by the natives, and killed, with the greater part of his men. The following year, the Azores—which, although lying nearly due west from Lisbon, have been considered by Malte-Brun, and other geographers, to belong properly to Africa—were discovered by Gonzalo Vello, and about twelve years after colonized under the auspices of Prince Henry, to whom a patent or charter was granted for that purpose by his nephew King Alphonso V.

In 1449 (Sousa says 1460, and other authorities 1462) the Cape Verde islands, the nearest of which lies about 300 miles west from that promontory, were discovered by Antonio di Noli, a Genoese in the service of Prince Henry. The prince died in 1463, at the age of sixty-seven; but the zeal for African discovery, which, in the face of long-continued ridicule and opposition, he had so far fostered, was now become a national passion, and the work of prosecuting what had been so well begun was taken up by the government. The coast of Sierra Leone, about 200 miles south of the Rio Grande, was reached in 1467. By the year 1469 the navigation had advanced as far as to the portion of northern Guinea, called the Grain Coast from the cochineal (then, and for a long time afterwards, erroneously supposed to be a vegetable seed) thence obtained; and in the course of that year Fernando Po discovered the island in the Bight of Biafra, now known by his name, but at first called Hermosa (the Fair). Fernando Gomez now obtained from the government, at a rent of 500 ducats, a monopoly of the commerce to Guinea for five years, binding himself during that period to explore 500 leagues more of the coast. Soon after were discovered Prince's Island (about lat. 1° 50′ N.), that of St. Thomas (nearly on the line), and that of Anno Bom (about 1° 40′ S.). In 1471, John de Santarem and Pedro de Escalona advanced as far as Cape St. Catharine, in lat. 2° 30′ S. This was the farthest point reached during the reign of Alphonso, who died in 1481, and was succeeded by his son John II. That same year the Castle or Fort of St. George of Elmina (the mine) was built by the government near the mouth of the river called Oro da Mina, on the Gold Coast, and became henceforth the capital of the Portuguese settlements; and soon after the new king added to his other titles that of Senhor de Guiné (Lord of Guinea). After this the circumnavigation of Africa was prosecuted with renewed spirit. The deep Gulf of Guinea had now carried the coast about 27°, east of the meridian of Cape Verde, and it was not found again to recede westwards. In 1484 took place the voyage of Diego Cam. He sailed from Elmina, and advanced as far as the River Congo or Zaire, the outlet of which is about lat. 6° S., after having ascended which for some miles he returned, and pursued his way along the coast till he reached first what he called Cape St. Augustine (in lat. 13° S.), and after that Cape Cross, or de Padrono (in lat. 22° S.). At each of these points he set up a great cross of stone, having inscribed upon it the king's name and his own, with the date and other particulars of its erection.

The next was the celebrated voyage of Bartholomew Diaz, who, setting out with three ships, was commanded, if possible, to pursue his course to the south until he should arrive at the extremity of the continent. Having accordingly passed the farthest point reached by Diego Cam, he proceeded until he came to what is now called Sierra Parda (in lat. 24° S.), where he erected his first cross, calling it Padraõ de Santiago. He then passed on till he reached Cape das Voltas (about lat. 29° S.), where he was detained for five days. On leaving this station he was driven out to sea, when, attempting to regain the coast, he came to what he named the Angra dos Vagueiros (or Bay of Herdsmen), and found the land stretching to the north. He had, in fact, doubled the terminating point of the African continent without knowing it. He continued his voyage past the Bay of Herdsmen till he came to a small island in the recess of Algoa Bay, which he named Santa Cruz, or the Holy Cross (in lat. 33° 45′ S.), where his crew, according to Barros, compelled him to put back after he had erected his second cross. Other accounts, however, state that he proceeded for about twenty-five leagues beyond this, when he found himself at the mouth of the river Del Infante, so called after the second captain, by whom it was first perceived. On his way back, Diaz came in sight of the long-sought promontory which we now call the Cape of Good Hope, the name given to it by the Portuguese king; but Diaz himself had named it Cabo Tormentoso (the Cape of Tempests), from the stormy sea which he encountered in its neighbourhood. The Cape of Good Hope was also sometimes called at first the Lion of the Sea, and the Head of Africa.

The beginning of the year 1493 was signalized by the return of Columbus from the discovery of America, then imagined to be the western termination of India with respect to Europe, and thence named the West Indies. But this was not the only great achievement in navigation which marked the close of this century. John II. of Portugal died in 1495, and was succeeded by his cousin Emanuel, surnamed the Great, who, with the throne, inherited all the zeal for maritime discovery which had distinguished its late possessor. Under his direction Vasco de Gama set sail on the 8th of July, 1497, to attempt the passage to India by the course around the extremity of Africa discovered by Diaz. In the prosecution of this enterprise, De Gama, after having doubled the Cape of Good Hope on the 19th of November, and put in at the bay of San Blaz, sixty leagues beyond it, left that station on the 8th of December, and on the 16th passed the island or rock of Santa Cruz, where Diaz had erected his last cross. He then came to the mouth of a river which he named Dos Reis (the River of the Kings), from having discovered it on Epiphany day. The part of the coast to the south of this he had called Tierra de Natal, in allusion to the season of Christmas. To the portion beyond, where he had some intercourse with the natives, he gave the name of the Land of Good People. The next place at which he touched was the Cabo de Correntes (that is, the Cape of Currents), near the tropic of Capricorn; from which keeping out to sea, he passed the river and rather deep of Sofala, without having observed the town there situated. Continuing his course to the north-east, he next arrived at the Port of Mozambique (in lat. 15° S.), but did not land, having discovered a plot of the Arabs there established to effect his destruction. By mistake he passed Quiloa, at which he had intended to put in, having been falsely informed that its inhabitants were Christians; and the force of the currents preventing him from making his way back, he pushed forward for the town of Mòmbaça, which stands upon a projecting point of the coast in lat. 3° 30′ S. From this station he was also induced to take his departure after remaining about a week, on discovering reason to believe that some treachery was intended him; when he set sail, and the same day arrived at the town of Melinda, about fifty miles farther to the north. Here he remained for some days, and then, leaving the coast of Africa, steered right across the ocean to India. On his return from this great expedition he passed in sight of the town of Magadoxa (more correctly Mukdeesha), in lat. 3° N., and also, in proceeding along the coast, touched at some other places besides those which he had visited in his voyage out. The ships of Portugal had now, therefore, navigated the whole extent of the African coast, from the Straits of Gibraltar to the Straits of Bab el Mandeb at the entrance of the Red Sea, with the exception of the space of about a thousand miles from the latter straits to Mukdeesha. They had ascertained the general shape of the continent to this extent, and the position, at least, of most of the principal rivers and headlands. To the nations of Europe the whole of the coast, the line of which had thus been traced, had been before entirely unknown, excepting, as already mentioned, the six hundred miles, or thereabouts, extending as far as to Cape Nun. But the Arabs had long been acquainted with the greater part of the east coast, along which Vasco de Gama passed after doubling the Cape of Good Hope; and the several great towns which he saw or heard of, from Sofala onwards to Magadoxa, were, in fact, for the most part, settlements which they had established, and where they possessed, in all cases really, in some cases also nominally, the supreme authority. The chief of these Arab settlements was the town of Quiloa.

But, in addition to this acquaintance with the coast, the Portuguese, in course of time, also acquired considerable knowledge of the inland country, partly through the establishments which they soon began to form at different points, and partly by means of information that was brought to them from other parts by the natives. One of the main objects kept in view in their early expeditions was the discovery of the residence of the mysterious personage known under the name of the Priest John (Preste Joaõ) or Prester John, as it has been Englished, of whom we shall only say here that, whoever he may have really been, he was, from the first intercourse with Abyssinia, taken to be the Emperor of that country. About the time of Diego Cam's voyage to the Congo, commercial relations were entered into by the garrison of Elmina with the King of Benin, the region lying at the head of the Gulf of Guinea; and from the people of this kingdom, intelligence was received of a great potentate whom they called King Ogané, living at a place 250 leagues in the interior, from whom each sovereign of Benin, on his accession to the throne, was said to receive a sort of investiture. It was immediately concluded by the Portuguese, that this could be nobody but Prester John; but Ogané was, no doubt, merely one of the great mo narchies in the interior, in all probability that called Ghana by Edrisi, and Kano by Clapperton, which, although now much reduced, is represented as having been formerly one of the most powerful in Africa. In 1487, also, two persons were sent out from Lisbon to attempt to find out the dominions of Prester John, and a route to India by land; and one of these, proceeding by Cairo and Aden, reached Goa in India, returned thence by Sofala, and afterwards penetrated into Abyssinia, where he was detained for some years. At Sofala he heard of the great island of Madagascar, called by the Portuguese at first St. Lawrence, the existence of which, however, had been long before made known to Europe by Marco Polo. Several natives of Africa, likewise, were at different times induced to visit Lisbon. Immediately before the adventurers we have just mentioned set out on their enterprise, a negro prince named Bemoi, from the nation of the Jaloffs or Yaloffs, to the south of the Senegal, arrived in that city to solicit the assistance of the Portuguese to replace him on his throne, from which he had been driven by some rival. This application afforded those to whom it was made a favourable opportunity of introducing themselves into this part of Africa, of which they immediately took advantage. They soon formed various establishments in the space lying between the Senegal and the Gambia, and along the banks of these rivers; but although they eventually spread themselves to such an extent in this district as to create a large population of mixed Portuguese and African blood, it is not exactly ascertained how far they actually penetrated into the interior. They, also, however, in course of time, acquired important settlements further to the south, along the banks of the Zaire, and in other parts of Congo; and the information which was obtained during the earlier period of their domination here respecting the geography of that and the neighbouring regions has been more fully given to the world. It was derived principally through the successive missions which were sent out, in the course of the seventeenth century, to attempt to christianise the inhabitants; and the greater part of it is to be found in Labat's *Relation Historique de l'Ethiopie Occidentale*, published at Paris, in 5 vols. 12mo., in 1732, with maps by D'Anville. The country actually traversed by the missionaries may be generally described as extending along the coast from Cape Lopo Gonzalves, in lat. 0° 44′ S., to the town of San Felippe de Benguela, in lat. 12° 14′ S., and as far in the interior as to Concabella, on the Zaire, about 400 miles from the mouth of that river, and to Massignan, about 100 miles up the more southerly river called the Coanza. They also obtained some information respecting parts beyond these points, which they did not visit. Finally, this nation very soon, also, established themselves along the east coast of Africa by the conquest of Quiloa, Mombaza, and Melinda from the Arabs, effected in 1505, and by the forts which they subsequently built on the island of Mozambique, (which became the capital of their eastern settlements,) and along the banks of the river Zambezi, a short distance to the north of Sofala. From these positions they obtained accounts more or less accurate respecting the whole coast of Zanguebar and Ajan as far north as to Cape Guardafui, which may be found in Barros. They had also some intercourse with the Macooa or Makooana, whose territory, lying some days' journey from the coast, is described as extending from behind Melinda as far south as to the Zambezi. On that river they have still factories at Tete, nearly 400 miles from its mouth, and at Zambo, which is almost twice that distance inland. The most recent account which has been given to the world of the Portuguese settlements both on this and the opposite coast, is Mr. Bowdich's work entitled *An Account of the Discoveries of the Portuguese in the Interior of Angola and Mozambique*, Lond. 1824. This volume, the information presented in which was derived partly from original manuscripts and partly from the communications of Count Saldanha de Gama, who had been for some time governor-general of Angola, contains maps of the country between the two seas, as far as it is known. In Mr. Bowdich's map, Manica, which is the principal mart for the trade carried on with the natives by the settlers on the east coast in gold, ivory, and slaves, is placed nearly on the 19th parallel of latitude, and in long. 31° 30′ E. from Greenwich.

It has been maintained by some writers that, long before Cape Nun was passed by the Portuguese, settlements had been formed on the coast of Africa by the French, very far to the south of that Cape. The Abbé Labat, to whom we have just referred, and after him the Abbé Demanet, in his *Nouvelle Histoire de l'Afrique Française*, 2 tom. 12mo., Paris, 1767, assure us that so early as the middle of the fourteenth century, the merchants of Dieppe had establishments and a trade at Rusisque, three leagues south from Cape Verde, and that by 1364 they had extended their intercourse as far as to the river of Sierra Leone. In 1365, these writers go on to say, a company was formed at Rouen for African commerce, which, the following year, founded depôts at Rusisque, on the Niger (by which is meant the Senegal), on the Gambia, on the Sierra Leone river, and along the Grain coast. One of these settlements, it seems, was called Little Paris, and another Little Dieppe. In 1382, the company built the Fort of La Mine d'Or, on the Gold coast, and also those of Acora, Cormentin, and others. All these establishments, however, they after some time abandoned, except those on the Senegal. As the authority for this history the Norman chronicles are appealed to; but still we cannot yield it our unhesitating belief. What is more certainly known with regard to the early intercourse of the French with the west coast of Africa, is that they appear to have been in the practice of sending four or five ships annually from Normandy to the river Gambia, soon after the middle of the sixteenth century. This is mentioned by the writer of the account of an English voyage to the Guinea coast, in 1591, printed in the second volume of Hakluyt's Collection. The company to whom these vessels belonged were certainly also possessed of some settlements in the neighbourhood of the Senegal, when, in 1664, they were compelled to sell them to the West India Company, that year established by royal charter. This association, however, broke up in 1673, when its African establishments fell into the hands of a new company. The Dutch had by this time obtained possession of the isles of Goree and Arguin; but they were driven from both in 1678 and the following year, by an armament sent from France under the conduct of the Count d'Estrées; and at the peace of Nimeguen these conquests were retained by the French king, who gave them up to the company. Demanet states, that, by treaties with the native princes, possession was subsequently obtained of all the coast from Cape Verde to the river Gambia,—being an extent of about fifty leagues—and to the depth of six leagues inland. French Africa, however, eventually comprehended much wider limits than these, stretching from Cape Blanco to Sierra Leone, or over about thirteen degrees of latitude, and going back also into the interior along the Senegal for some hundreds of miles. We do not mean that the company had acquired the sovereignty of all this territory; but that their settlements were spread from one extremity of it to the other.

The French African Company, however, repeatedly failed as a commercial speculation; and besides the one formed in 1673, which became bankrupt in 1681, two others had been successively associated and dissolved, when, in 1717, the trade was, by an edict of the crown, transferred from a third to the famous Western or Mississippi Company then newly established. On the failure of this short lived scheme the African settlements were taken possession of by the crown, and the trade left free. France still possesses, in this part of Africa, some inconsiderable settlements.

Several journeys into the interior were undertaken by the French residents at the mouth of the Senegal about the close of the seventeenth and the commencement of the eighteenth century, accounts of which are given in Labat's *Nouvelle Relation de l'Afrique Occidentale*, 5 vols. 12mo. Paris, 1728. The most important of these were the voyages performed up the Senegal by the Sieur Brue, the manager of one of the companies, in 1697 and 1698. In the former year he ascended the river for about 400 miles, when he landed at Ghiorel, on the north bank, and proceeded across the country to Goumel, the capital of the king of the Foulahs, about thirty leagues distant. On his return from this journey he established a factory at Ghiorel. The following year he again proceeded up the river, and visited several more remote parts of the kingdom of Gallam. The town of Dramanet, the principal port of that state, he found to contain 4000 inhabitants, who traded with Timbuctoo, which they described as lying about 500 leagues further inland. The French afterwards established a factory at Dramanet. He extended his voyage up the river as far beyond this point as to the cataract of Felu, and then leaving the water passed that barrier by land, intending to proceed to the cataract of Govinea, forty leagues higher up. But the apprehension of the water becoming too shallow from the heat of the advancing season to carry him back, induced him to return without accomplishing that object. He heard, however, while in Gallam, of the kingdom of Kasson, situated to the north-east of it, and of Bambarra beyond that. East of Bambarra, he was told, lay Timbuctoo, and beyond that the kingdom of Ghingala. He was also positively assured by some of his informants (although the statement was contradicted by others) that the Niger, which he supposed to be the same with the Senegal, flowed not towards the west, but towards the east, as it passed Timbuctoo.

It was not till some years after this time, that the French appear to have heard of the kingdom of Bambouk, lying to the south of Gallam, although it had formed part of the conquests of the Portuguese, whom, however, the natives had expelled after long experience of their oppression. But no sooner was intelligence obtained of the gold dust and mines in which it was said to abound, than the avidity of the new colonists of the Senegal was powerfully awakened, and every effort was employed to penetrate its frontiers, an attempt rendered infinitely difficult and hazardous by the vigilant jealousy of the inhabitants, who had not yet forgotten the miseries of European tyranny. The perilous undertaking, however, was at length accomplished in 1714, by M. Compagnon, who contrived to traverse nearly the whole of the territory. It was afterwards repeatedly visited by others of the French residents; and, in 1802 a full account of it was given in the first volume of M. Golberry's *Fragmens d'un Voyage en Afrique*, from the communications of the negroes and of the English established on the Gambia, from a work which he describes as printed in England in 1782, and from the memoirs of Governors Levens, David, and others, who had repeatedly been in the country between 1730 and 1744. M. Golberry's book has been translated into English. The kingdom of Gallam was also visited in 1785 by M. Saugnier, an account of whose journey has been published. The kingdom of Hoval, likewise, from which gum Senegal is brought, and which occupies the space between the Senegal and the Sahara, was early explored by the French settlers. An account of a journey thither by the Sieur Brue is to be found in Labat; and much additional information respecting the country is given in the work of M. Golberry.

Settlements upon the west coast of Africa were also early made in imitation of the Portuguese and French, first by the English and afterwards by the Dutch; and some of the English traders repeatedly ascended to a considerable height on the Gambia. The Danes have also some small establishments on the Guinea coast. But it is since the formation of the AFRICAN ASSOCIATION, in 1788, that the chief efforts have been made in the prosecution of discovery in the interior. The expeditions sent out by the Association and by government, and those undertaken by individual adventurers, have sought Timbuctoo and the Niger from various points. But no considerable progress was made till the first journey in 1795 and 1796 of Park, who on that occasion proceeding from the west coast in the direction of the Gambia, till he left it and turned to the north at Medina, after passing through the kingdoms of Bondou, Kasson, and Kaarta, reached Sego, the capital of Bambarra, and there beheld the Niger (called by the natives the Joliba, or Great Water) 'flowing slowly to the eastward.' Park advanced beyond this point to another town named Silla, on the same river, and also acquired some valuable information respecting the further course of the Niger and the position of Timbuctoo, which he was told was not more than 200 miles from Silla. He returned to the Gambia by a more southerly tract, following the course of the Niger as far up as Bammakoo, which was stated to be about ten days' journey from its source, and then proceeding through the mountainous districts of Manding, Konkodoo, and Dindikoo. On his second expedition, which was undertaken at the public expense, in 1805, this adventurous traveller, after again reaching Silla, embarked on the Niger at Sansanding in its vicinity, with the purpose of sailing down the river to its mouth, wherever that might be. He is ascertained to have passed in succession the cities of Jenné, Timbuctoo, and Yaour, or Yaouri, and to have been killed in the river at Boussa, a short distance below the last; but no part of his journal after he left Sansanding has been recovered. Meanwhile, now that the interest taken in African geography had become strong and general, a good deal of information was collected from a variety of sources respecting both the regions in the interior and some parts nearer the coast. Hornemann, who, in 1799, penetrated from Cairo to Mourzouk, in the desert, and on the line of the common route from Tripoli to Timbuctoo, learned many particulars which had not before been known in Europe respecting the countries to the east of Timbuctoo, and especially the kingdom of Bornou, then the most powerful state in Central Africa. Mr. Riley, supercargo of an American vessel, who had been taken captive by the natives in 1815, and carried into the interior, obtained from the information of an Arab merchant by whom he had been purchased, an account of the course of the Joliba, to a greater distance beyond Timbuctoo than previous notices had carried it; but his statements were evidently not to be altogether depended on. In 1816, an expedition sent out by government under the command of Captain Tuckey, to the Congo, in the idea that it would be found to be the same with the Joliba or Niger, ascended that river for about 280 miles, and also examined part of the adjacent country. At the same time, Major Peddie, and after his death Captain Campbell, conducted another party from the mouth of the Senegal through the Foulah territory as far as Kakundy. In 1817, Mr. Bowdich explored a part of the extensive territories of the Ashantees, surrounding, on the north, east, and west, the district of the Fantees, who occupy that part of the coast of Guinea where the English settlement of Cape Coast Castle is established. In 1820, very considerable additions were made to the knowledge formerly possessed both of the geography and the people of interior Africa, by the publication of Mr. Jackson's account of the territories of Timbuctoo and Houssa, from the communications of El Hage Abd Salam Shabeeny, a Mussulman merchant, who had visited these states. This year also appeared at Paris the account of a journey made by M. Mollien to the sources of the Senegal and the Gambia, in which, setting out from the isle of St. Louis, at the mouth of the Senegal, he traversed the country in a south-easterly direction as far as the town of Timbo, nearly in 10° N. lat. and above 14° W. long. from Greenwich. Some further information was also obtained by means of the expedition of Messrs. Ritchie and Lyon, who, in 1819, penetrated from Tripoli to Mourzouk; and from the journey performed, in 1821, by Major Laing, from Sierra Leone, through the Timannee, Kooranko, and Soolima countries.

But a more important and successful attempt than any which had been hitherto made to explore the interior of Africa was that of Major Denham and Lieutenant Clapperton in 1822. These travellers, setting out from Tripoli along with a caravan of Arab merchants, crossed the desert and reached the great inland sea or lake called the Tchad, the coasts of which, to the west and south, were examined by Major Denham, while Lieutenant Clapperton proceeded to the westward through the kingdom of Bornou and the country of the Fellatahs, till he arrived at Sackatoo, situated on a stream which probably runs into the Joliba. A great mass of information respecting these hitherto unvisited regions, lying to the east of Timbuctoo, was obtained in the course of this expedition; but not much that could be depended on was learned as to the remaining course of the Niger, or the Quorra, as it was found to be called at Sackatoo. It was very generally stated to flow into the sea at Funda, but where that place was could not be exactly ascertained. Soon after Clapperton's return to England, however, he was sent out by the government in the command of a new expedition, the plan being that he should endeavour to penetrate to the scene of his former adventures from the coast of Guinea. He accordingly set out for the interior from Badagry, a short distance to the east of Cape Coast Castle, and taking a north-easterly direction proceeded through the kingdom of Yarriba, or Eyeo, till he reached the Niger at Boussa, where Park perished. Crossing the river, he entered the kingdom of Nyffe, after traversing which, and some of the adjoining districts as far as the great commercial city of Kano, the capital of Houssa, where he had been in his former journey, he turned again to the west, and, reaching Sackatoo, there died. His servant, Richard Lander, afterwards returned to Kano, and proceeded thence through the kingdom of Zegzeg, a considerable way towards the south, intending to embark on one of the branches of the Niger, and, if possible, to solve the grand problem of its termination by sailing down the stream. But he was stopped by the natives, and compelled to turn back when he had got as far as Dunrora, which he understood to be due west of Funda, and at no great distance from it. Meanwhile, Major Laing, already mentioned, had succeeded in making his way across the desert from Tripoli to Timbuctoo, in August, 1826, and had transmitted some brief notices of that famous city, where he spent some weeks. But he was murdered on his return, in the desert, and none of his papers have yet been recovered. There has also been lately published an account of a journey from Sierra Leone to Timbuctoo, performed by a M. Caillé, a native of France; but although the truth of his narrative in its principal statements is now generally admitted, it is so extremely loose in its geographical details, that it cannot be said to have added much valuable information to our knowledge of the countries to which it relates. The discovery of the long-sought termination of the Joliba, Quorra, or Niger, however, has since been effected by the fortunate and well-conducted enterprise of Richard Lander and his brother. Leaving Badagry on the 22d of March, 1830, these two travellers, following nearly the same route which had been taken by Clapperton through the kingdom of Eyeo, reached Boussa, on the 17th of June. They afterwards ascended the river as far as Yaouri, from which they returned to Boussa, where they remained for some time, and then embarked on the river which they hoped would conduct them to the sea. In this expectation they were not disappointed. After various adventures, Richard Lander had at last the happiness, on the evening of the 18th of November, to find himself at the mouth of the greater branch of the river, here called the river Nun, or the First Brass River, from the negro town of Brass which stands upon its banks a short distance inland. There is another great branch entering the sea a few miles more to the south, called the second Brass River. The traveller was afterwards joined by his brother; and the two reached Portsmouth together on the 9th of June, 1831. They left England again with two steam-vessels and a transport, which were built and fitted out by some spirited merchants of Liverpool for the purpose of attempting the ascent of the Niger, if possible, as far as to Sackatoo or Timbuctoo. This expedition sailed on the 27th of July, and the latest accounts that have been received of it were dated the 11th of October, 1832, at which time it had safely reached Cape Coast Castle.

The zeal for discovery in Africa, which has been so strongly felt within the last half century, has also sent out a succession of travellers to explore the southern regions of that vast continent. The principal settlement in this quarter, that of the Cape of Good Hope, was founded by the Dutch about 1650, and remained in their hands till it was finally taken from them by the British in 1806. For more than a hundred years after the establishment of this colony, it occupied only the extreme angle of the African continent, or a part of the narrow stripe between the sea and the nearest mountains; nor does much information seem to have been obtained with regard to any of the native tribes, except the nearest Hottentots, lying beyond that boundary. The first traveller who penetrated any considerable way into the interior was Captain Henri Hop, who was sent out on an expedition of discovery by the Dutch governor in 1761, and traversed a considerable part of the country of the Namaquas. He was followed by the Swedish naturalist Sparrman, and by Vaillant, whose journeys were made between 1775 and 1785, and extended to the territory of the Bosjesmans, three or four hundred miles north from Cape Town. In 1797, the regions lying in this direction were traversed by Mr. Barrow from the territory of the Caffres in the east, to that of the Namaquas in the west, including the desert of the Great Karroo, and as far north as the foot of the Sneuwberg, or Snow mountains. In 1801, the great barrier formed by this range was for the first time passed by Messrs. Trutter and Somerville, who, crossing the Gariep or Orange River, penetrated as far as Leetakoo, or Lattakoo, the capital of the Boshuanas. Soon after another party, under the conduct of Dr. Cowan and Lieutenant Donovan, was sent out from Cape Town to cross the country to Mozambique, or Sofala, and accounts were received from them when they had advanced eleven days' journey beyond Lattakoo. But here, in the country of the Wanketzens or Wanketchies, the unfortunate adventurers appear to have been destroyed by the natives. A few years after, Dr. Henry Lichtenstein penetrated as far as Lattakoo, and brought back much more complete information respecting the Boshuanas, and the other tribes whose territories he traversed, than had been before obtained. Mr. Burchell also reached Lattakoo in 1812; and in the following year it was visited by Mr. John Campbell, the missionary. In 1820 the same gentleman returned to that capital, and proceeded thence as far east as to the hitherto unvisited city of Mashow, from which he directed his course northward till he reached Kureechanee, about latitude 25°. South-west from this last town he found himself on the borders of a desert which he was informed extended an immense distance to the westward. No traveller has since penetrated so far to the north as Mr. Campbell did in this journey; but in 1823, Lattakoo was once more visited by Mr. George Thompson, whose accounts of many parts of the country lying between this point and the colony, as well as of some of the Caffre tribes to the east, are much more complete than any that had before been given to the public. The map of South Africa, which is given in the second volume of Mr. Thompson's travels (Lond. 1827) is also, we believe, the fullest that has yet been published; but it is unfortunately so unskilfully lithographed as to be in many parts nearly illegible.

Our limits render it impossible to give even a brief sketch of the history of modern discovery in the Nile Valley, and other north-eastern parts of Africa not included in the above outline. We should not omit, however, the journey of Mr. Brown to Dar-Fûr in 1793, where he was detained nearly three years. Though his movements within Dar-Fûr were confined to a very limited space, his work contains a great deal of curious information on a country before that time totally unknown.

The expedition of the Beecheys in 1821 and 1822, from Tripoli eastward to the Great Syrtis and the Cyrenaica, has made us more intimately acquainted with a most interesting region, only imperfectly known from the earlier accounts of Della Cella and others.

Of Egypt we shall speak more particularly under that head, and for a brief notice of discovery in Abyssinia, we must also refer to that article. At the present time one of the missionary societies has its agents in Abyssinia, who, it is hoped, besides fulfilling the more important object of their mission, will add to our stock of information on that country, and thus by facilitating commercial intercourse, contribute still further to the social improvement of the numerous nations on this part of the continent. The travels of Caillaud to Chendy and into the kingdom of Sennaar (1822), and the travels of Rüppel in Nubia, Kordofan, &c., have added considerably to our knowledge of these regions. The latest expedition with which we are acquainted up the Bahr-el-Abiad, or main stream of the Nile, is that by Adolphe Linant, who, in 1827, advanced up this stream beyond Aleis. [See *Journal of London Geogr. Soc.*, vol. ii.]

The large island of Madagascar will require a separate notice. Our accounts of it are yet very incomplete, but we hope that the missionary settlements made in that island (since 1818) will gradually bring us still further acquainted with it. [See *Missionary Gazetteer*.]

III. The extent of the African coast, and the portions surveyed by each navigator, will be seen from the following tabular view:—

	Eng. Miles.	
From El Arish, 33° 55′ l. E. (a village near the conventional boundary line of Africa and Asia,) to Alexandria	238	There has been no actual survey of this part of the coast. Captain Gautier of the French navy merely sailed along and determined a few points on the coast.
From Alexandria to the Fratelli Rocks	1400	Surveyed by Capt. W. H. Smyth, R. N.
From the Fratelli Rocks to Cape Spartel	830	Partly surveyed by Capt. W. H. Smyth and the coast of Algiers by the French.
Cape Spartel to Cape Bojador	875	This part of the coast is but imperfectly known. The English and Spaniards have occasionally surveyed detached portions of it.
Cape Bojador to Cape Mirik	530	Cape Bojador to Cape Blanco was surveyed by Capt. Baldy, R. N.; and from Cape Blanco to Cape Mirik, the outer edge of the Bank of Arguin only, was surveyed by Baron Roussin; the line of coast not being visible.
Cape Mirik to Cape Verde	375	Surveyed by Baron Roussin of the French Navy.
Cape Verde to Cape Roxo	160	By Captain Boteler.
Cape Roxo to Tumba Point	300	Surveying by Capt. Belcher, R. N.
Tumba Point to the south side of Sherboro Island	150	By Capt. W. F. W. Owen.
South side of Sherboro Island to Cape Formosa	1470	Surveyed by Mr. Anthony de Mayne, Master R. N.
From the Cape Formosa to the Cape of Good Hope	3010	Surveyed by Capt. W. F. W. Owen, R. N.
From the Cape of Good Hope to Cape Guardafui	4550	Ditto, ditto.
Cape Guardafui to Ras Bir	610	This part of the coast has never been surveyed.
Ras Bir to Salaka	690	Now surveying by the East India Company's Marine.
Salaka to Suez	860	
	16,048	

IV. This enormous peninsula is attached to the Asiatic mass by the isthmus of Suez; but at two other points, the straits of Bab el Mandeb, and those of Gibraltar, it approaches close to the respective continents of Asia and Europe. The equator cuts it into two masses of unequal magnitude; though the extreme southern and northern coasts are, on an average, pretty nearly removed the same distance from the equinoctial line. The latitude of Ras el Krun near Bizerta is 37° 20′ N., and that of Cape das Agulhas, (Cape Needles,) the most southern part of the continent, is about 34° 50′S. The distance between these two points is about 5000 miles. The most remarkable projection of the African coast is that which terminates in the bold headland, called by the Portuguese Cape Guardafui, in N. lat. 11° 50′, E. lon. 51° 22′; this is the most eastern point of Africa. Its extreme western point is Cape Verde, N. lat. 14° 45′, W. lon. 17° 32′: the distance between these two capes, in a direct line, is not much less than 5000 miles.

The geographical position and coast line of Africa are characterized by lying for the most part within the tropics, and by the comparatively few deep indentations of the coast. Its northern shores are washed by the Mediterranean, and are the most irregular part of the African coast, presenting the indentations of the Arabs gulf, the large gulf of Sidra, and that of Cabes. Many parts of this shore, especially about the Sidra gulf, are low, but neither so sandy nor barren as some writers represent them; while the Cyrenaic regions, and a large part of the coast west of the Sidra, as far as the straits, is considerably elevated, and, perhaps, with the regions of Marocco, form the most favourable part of the whole African coast for the habitation of man. Only one river of any considerable magnitude, the Nile, flows from the African continent into the Mediterranean, but this is one of the most singular streams in the world, whose course the traveller may follow from the coast into the interior for above 1200 miles, without meeting with one single current that adds its waters to those of this mysterious river. The streams of the Atlas regions that enter the Atlantic, though numerous, are inconsiderable as to the volume of water: the chief is the Mejerdah, the ancient Magradas or Bagradas, which flows into the sea near Tunis, and is subject to periodical inundations in the lower part of its course; and the perhaps larger river Molooyah, which belongs to the empire of Marocco. The Atlantic washes the western coast of Africa, which, within the dominions of Marocco, presents a coast generally low, succeeded in the interior by fertile plains of immense extent. Numerous streams, some with a considerable length, of course, such as the Wad Seboo, Oom er begh, &c., flow from the Atlas into the Atlantic ocean within the limits of the empire of Marocco. South of this region, the arid character of the Sahara is found extending even to the shores of the ocean, and hardly disappearing before we arrive at the Senegal. From the Senegal to the Cape of Good Hope, the coast is now pretty well known, but the same minuteness of survey and of observation has not been applied to all parts of it. The great characteristic in its outline is the gulf of Guinea, the northern shores of which have a *general* direction east and west through 20° longitude. With the numerous rivers that flow into the Atlantic between the Senegal and Cape Negro, (N. lat. 16°,) we are still imperfectly acquainted; and the numerous openings that are observed on many parts of this coast indicate outlets of rivers, or channels formed by islands, which yet remain to be explored. The Senegal, Gambia, and Rio Grande, are the three largest rivers north of Sierra Leone, though the precise nature of the lower channels of the last-mentioned is not yet ascertained. Captain Belcher suspects the existence of an archipèlago of islands between the Rio Grande and the Nuñez. The late expedition of the Landers has determined the long doubtful question of the outlet of the Quorra in the bight of Benin; and the river Nun is now ascertained to be one of the several channels by which the Joliba of Parke discharges its waters into the Atlantic.

The great African river, south of the equator, is the Zayre or Congo, which is found, on ascending its stream, to show a less volume of water than would be inferred from its appearance at the mouth; but this is the case with other large African rivers, and leads to no safe conclusion as to its course being comparatively short. Between the Congo and Cape Negro there are numerous streams, such as the great Coanza, and others which are of minor importance when compared with the Congo and Coanza, which appear to be the great rivers of south-western, as the Zambezi is of south-eastern Africa. From Cape Negro or the Bambaroughe to the Orange river, we have a coast of 800 or 900 miles almost without fresh water. The Orange river is a large stream, perhaps the fourth or fifth among African rivers, whose course to the Atlantic is determined, though its numerous tributaries rise far in the interior, by the *general* slope of this part of the surface from east to west.

The Cape colony, within the limits now assigned to it, is now so far known, that its geographical features need not be noticed in this general sketch; but we may remark, that the common notion of Africa terminating in a point requires correction. The mountain ranges, and extensive plains which run east and west within the limits of the colony form a series of heights and terraces, which are bounded on the south by an extensive line of coast running in the same direction. From False Bay to the extremity of Algoa Bay, we have a line of coast above 400 miles long, running nearly due east and west, and presenting to the southern ocean as broad a front as the Spanish peninsula offers to the Atlantic.

The great known river of the eastern coast is the Zambezi, which, though low in the dry season, is provided with prodigious channels to receive the floods of the rainy months. Further north on this coast, near the site of Melinda, we find the outlets of streams from the interior; and it is *possible* that the Zebee here finds its way to the ocean; but, unlike the other south African streams, we are acquainted, from the narrative of Fernandez, with its upper course, which lies north of the equator, but not with its lower course near the coasts of the Indian ocean.

The great currents on the coast of Africa are too remarkable to be entirely passed over; but as those which are best known belong to the North and South ATLANTIC, a brief notice of that round the Cape will be all that is necessary here.

The great bank which lies off the coast of South Africa, and takes its name of Agulhas, or, as it is often incorrectly called, Lagulhas, from the cape of that name, has probably been partly formed by the action of currents. It is, indeed, probable that the main mass of it owes its existence to the same phenomena which produced the terrace lands of the Cape; but it has also received great accessions of sand and weed from the action of the currents. Two main streams, one from the Mozambique canal, the other from the open Indian Ocean, impelled by the S.E. trade-wind, unite nearly opposite to Cape Padron (26° 20′ E. long.). From the meridian of Cape Recif (25° 36′ E. long.) the main stream gradually turns to the west, and strikes on the great bank (in about 35° 30′ lat., 23° long.), by which its course is changed successively to W. 36° S. to S.W., and finally (in lat. 38°) it becomes rather east of south. The greatest portion of this current is actually turned round by the east edge of the bank, and finally mingles with a South Atlantic eastern current, and, impelled by it, thus returns into the Indian Ocean by a line nearly parallel to its original course. A *part* of the stream passes over the deep water at the southern extremity of the bank and turns towards the N.W., and then uniting opposite the Cape of Good Hope with another part of the main stream, (which *crosses* the northern part of the bank in a western direction, between 34° 45′, and 35° 40′,) forms a wide stream running to the N.W. as far as 25° S. lat., where it joins the N.W. current formed by the S.E. trade-wind. The existence and course of these currents are indicated not only by their actual motion, but also by their temperature. Off Cape Recif (Reef), where the temperature of the Mozambique stream was found (in June) to be somewhat lower than it was further north and east, it was still 68°, or 8° above the ocean temperature. On the bank, in lat. 35° 45′, it has been found 7° above ocean temperature; and diminishing westward towards the edge of the bank, it becomes of the ocean temperature for some distance before attaining its western extremity. But what is singular, and confirms the statement above made as to the current that *rounds* the Agulhas bank joining that which *crosses* it—the temperature rises again to 4° above the ocean temperature, *west* of the bank, as soon as the junction with the southern branch is effected. For further information on this current, the reader may refer to our authority (Major Rennell, *On the Currents of the Atlantic*, London, 1832). Salt, in his voyage up the Mozambique channel, found the current between Capes Correntes and Sebastian, setting strong to the south, so as 'to impede the course not less than sixty miles in twenty-four hours.' And further north (12° 37′ S. lat., 41° 24′ E. long.), Mr. Salt speaks of 'a strong current setting to the southward at the rate of thirty miles in twenty-four hours.'

On doubling Cape Guardafui the same writer experienced along the coast, a strong current that headed the ship; but the information which he gives about it leads to no conclusions. This current has no connexion with that just described.

The only other phenomenon of African currents, that requires a short notice here, is that part of the North African current, as Major Rennell calls it, which sets into the Mediterranean through the straits of Gibraltar. The great loss which the Mediterranean experiences from evaporation is supplied by a constant current pouring in from the Atlantic. This current is most obvious to the east of a line joining Cape St. Vincent in Spain, and Cape Cantin (32° 35′N. lat.) in Africa. The form of the coasts is like the wide part of a funnel, and the straits of Gibraltar are the pipe. It is probably owing to this rush of water towards the straits that an eastern current has been perceived, in summer, as far as the Azores, increasing in velocity eastward from the meridian of Cape Vincent. South of the latitude of the Canaries and Cape Bojador, the current, instead of pointing to the straits' mouth, sets upon the coast of the Great Desert, which is sandy and low. This current, from whatever cause it arises, is that which has brought so many ships on this inhospitable shore, navigators having been deceived in their reckoning by not estimating the force of the stream. Ships' crews that have had the misfortune to be cast on this savage coast, inhabited by a brutish race of barbarians, have frequently either perished of hunger, or been sold into slavery. [See Rennell.]

Africa seems to be a land of terraces, as indeed all widely extended portions of the earth's surface probably are. It would appear in general to rise from the coast into the interior by successive steps, which are spread out in widely extended plains. These are known to exist in some parts, such as in the Cape Colony, and are indicated in others by a regular series of falls in the beds of the great rivers—the Nile, Quorra, Congo, &c. We know from Tuckey's expedition up the Congo, that mountains of considerable elevation are found at no great distance in the interior; and the late expedition up the Zambezi, (see *London Geographical Journal*, vol. ii.,) in addition to former accounts, has confirmed the opinion of the country rising into considerable elevations in the interior. The numerous tributaries of the Zambezi, and the immense body of water which it brings down, indicate sufficiently its extensive course and the existence of elevated regions in the interior. But we are almost entirely ignorant of the conformation of all Southern Africa, with the exception of the Cape colony, and our limited knowledge of the coasts. The existence of a large chain like the Andes, as some have imagined, running north and south, is not only unproved, but improbable. The existence of elevated table-lands is, however, certain. There is no account of either native or European having crossed this immense continent south of the Sahara; nor have the Portuguese ever effected a line of communication between their settlements on the Angola and Mozambique coasts, though enterprising individuals and traders have on each side advanced far into the interior; and an instance is recorded of a person having crossed the country from Angola, on the west coast, to Tete, on the Zambezi river, at both of which places he had seen the Portuguese flag. [See Bowdich's *Account of the Discoveries of the Portuguese in Angola and Mozambique*.]

The mountain system of Africa must, in many cases, be inferred from the course of the great rivers. The high lands of Abyssinia, in which the Tacazze and the Bahr-el-Azrek rise, are in all probability continued westward, if not at so great an elevation, at least at a very considerable one. But whether these western regions run step by step to a central mountain range, or spread out in wide plateaus or deserts, we do not know. From this remote region the waters of the Bahr-el-Abiad, or true Nile, descend; and from a somewhat lower elevation, probably the Misselad and other streams that find their way into interior lakes. It seems now pretty certain that a range of land stretches across the continent, so as to separate the basin of the Congo from that of the Tchad Lake and its affluents, while the basin of the Quorra is again separated from that of the Tchad by a ridge of small elevation running in a northerly direction. But the distance from the supposed sources of the Bahr-el-Abiad to the high lands seen by the Landers from the Quorra in the neighbourhood of Funda is so great, that it would be a hasty assumption to suppose a mountain chain continuous across the continent. The high lands east of the Quorra, about Funda, seem to belong to the same elevation which runs west of the Quorra, and then north, and supplies on one side the water of the Senegal, Gambia, and other streams to the south, and on the other feeds the Joliba or Quorra.

The expeditions of Denham and Clapperton have made us acquainted with a large internal lake, the Tchad, which, from its extent and position, forms one of the most remarkable features in the physical geography of this continent. Africa, as far as we yet know it, contains comparatively few lakes. The lake of Maravi, about sixty leagues north of Tete, is still unexplored, but this has been no obstacle to assigning it a most prodigious length: that of Dembea in Abyssinia, Keroun in Lower Egypt, Dibbie, through which the Joliba flows, Fittrie, and the lakes of the Atlas regions, are all inconsiderable when compared with the Tchad, which, though its dimensions are not yet ascertained, must occupy a very extensive surface, especially during the rainy season. The elevation of the Tchad above the sea may probably not be more than from 400 to 600 feet.

The interior country watered by the Quorra, by the tributaries to the Tchad, and by other unknown streams that probably exist, may be in general described as a fertile region, well suited to the habitation of man, and apparently not possessing a climate unfavourable to life, either for the natives, or Europeans who know how to take care of themselves. This country, known by the general name of Soudan, cannot be accurately defined. Dar-Fûr would seem to be properly included in it, though it partakes also of the character of the neighbouring Sahara, and forms a kind of oasis; but the periodical rains from before the middle of June to the middle or end of September, and the presence of the elephant and hippopotamus in some parts of the country, mark these at least as belonging to the Soudan regions. The winds that fill Dar-Fûr with thick dust blow constantly from the south, and are the hot winds,—thus indicating a considerable extent of southern country of a low and sandy character.

The great characteristic feature of Northern Africa, the Sahara or Great Desert, would form a complete physical barrier between the Mediterranean and the interior but for the long and narrow valley of the Nile; which, in fact, bounded as it is in many parts on the west by a high rocky barrier of limestone, from which the traveller descends to the lower region of the western desert, may be considered as a separate portion of the continent. The broad belt of the desert stretching across the continent seems as if it were only interrupted by the Nile, to recommence with the same arid character in the broad wastes of Arabia and the Syrian desert. Arabia, in fact, in its physical conformation, belongs rather to Africa than Asia. But this extensive waste is not so uniform in its appearance as to be one mass of sand. Its surface is in various parts of very unequal elevation. Occasionally it rises into rugged barren ranges of hills, some of which, of limestone formation, contain marine shells; and sometimes, particularly in the eastern part, it is diversified with springs of water, both warm and cold, which give fertility to the small spots around them, which were called by the Greeks, oases, the same word as the modern wady. The Sahara, indeed, may be divided into two great divisions, of which the eastern is far more diversified with springs and habitable spots; the western portion, through which the traders from Marocco make their way to the Joliba, is the most barren, parched, and terrific waste on the surface of our globe. The abundant supply of natron (sesqui-carbonate of soda) and common salt contained in the salt lakes of the Sahara, and some which is found in a fossil state, has always furnished an important article of trade between the people of the desert and Soudan, where this necessary of life is wanting. The western portion of this desert is less known than the route from Mourzouk to Bornou, and presents, as we have said, a far more fearful and extended waste than the eastern division; it stretches westward to the very shores of the Atlantic, displaying on the coasts of the ocean the same desolate and sandy appearance. We have yet no observations sufficiently accurate or numerous to determine the general elevation of the Sahara, though there can be little doubt that it contains many uninterrupted levels of considerable height. (See SAHARA.)

The countries north of the Sahara from the southern limits of the empire of Marocco, nearly as far as the Gulf of Sidra, are sometimes comprehended under the general name of the Atlas regions, so called from the predominant mountain range to which that name is given. The various branches and the geological character of this range will be described under the head of Atlas. This region contains on the Atlantic coast fertile plains, bounded to the east by mountains covered with eternal snow. On the Mediterranean coast the level country is of much less extent, and the interior is a region of elevated ground filled with hills and mountains. Our imperfect knowledge of this interesting region will, no doubt, soon receive extensive accessions from the French and others who have settled in the territory of Algiers. The Arab geographers considered this tract as more European than African in its character and position, an opinion which the physical features of the opposite Spanish peninsula, with its Sierra Nevada, its climate and productions, fully justify. We cannot yet assign satisfactorily any eastern limits to the *physical* region, which may be considered as belonging to the Atlas country. The gulf of Cabes, or rather the promontory of Cape Bon, may perhaps be assumed as its extreme limit along the coast, while, in the interior, a mountain range, the Ghurian, of no very great elevation, extends at least as far eastward as the western side of the coast of the gulf of Sidra. To avoid these mountains, the Fezzan caravans sometimes take the route through Mesurata on the coast.

The high lands of the ancient Cyrenaica, now included within the limits of what is often incorrectly termed the *desert* of Barca, form a separate system, and will require a distinct description.

It has been often remarked that Africa shows few, if any, traces of volcanic action within historical periods, and the occurrence of earthquakes is not established on record, except within the limits of Egypt. But undoubted traces of the former action of subterraneous fire are to be found; for instance, on the west coast on the banks of the Nuñez, and most particularly in the Canaries, the Cape Verde archipelago, the small islands at the mouth of the Rio Grande, and those in the bight of Biafra. Jebel Teir, a small island in the Red Sea, is an extinct volcano.

The mineral treasures of this immense continent are of course very imperfectly known. Salt is perhaps one of the most universally diffused, being found from the salt lakes of the Cape colony to the northern coast, and yet extensive districts, as we have already remarked, such as the Soudan, are without it. But it occurs again south of the equator, and is plentifully procured from the salt quarries of Angola; and Brown mentions it also as being found in a fossil state in Dar-Fûr. It will probably be found on inquiry that the mineral treasures of Africa are nearly as various as those of other parts of the world, though at present less imperfectly known, and in many cases only observed at spots widely removed from one another. The mineral wealth of Egypt alone is considerable; and that of the interior west of the Mozambique coast is also abundant. Gold dust, however, is that which has the most excited the cupidity of Europeans; and this mineral is found in the sands of the upper streams of nearly all the great African rivers.

The following are the chief African minerals and earths known to commerce, or the useful arts, with some of the countries in which they are found. It should be remembered that they are found in other places than those here enumerated.

Gold.—Central Nigritia, Guinea coast, Mozambique coast, &c.

Silver.—Mines said to be at Chicova, up the Zambezi river. (See Bowdich, *Account of Discoveries*, &c.); Elala in S.W. part of Marocco.

Copper.—Mines of Fertit, south of Dar-Fûr; Atlas mountains; Egypt, &c.; the Moolwas; Zumbo, on the Zambezi, &c.

Iron.—Egypt; Dar-Fûr; on the banks of the Lucala, a branch of the Coanza; in the territory of the Cazembes, &c.

Tin.—Loango. (Bowdich.)

Salt.—Egypt, Tunis, Sahara, Angola, the Cape of Good Hope, Abyssinia, Dar-Fûr.

Lead.—Loango. (Bowdich.)

Chalk.—Dar-Fûr.

Sulphur.—Benguela; Cassandama? Kebrit on the Tripoli coast. (Beechey.)

Coal.—Zumbo. (Bowdich.)

V. THE MAN OF AFRICA. This extensive continent is characterized by certain varieties of the human species, which it will be useful here to distribute into their proper families as accurately as we can, in order to obviate that confusion which is often found in common treatises on geography. We propose merely to give such a general outline of the distribution of the human race in this continent as may show the large masses into which it divides itself: the subdivisions of nations and tribes will be found under other heads. The following sketch is founded chiefly on those *physical* differences, which characterize the animal man in Africa. The reader may see in Balbi's *Abrégé de Géographie*, the classification of the people according to *languages*, of which we will only remark, that we consider it at present impossible to make a classification of African languages without running the risk of almost endless error.

The southern regions of Africa are occupied by two nations, the Hottentots and Caffres. The Hottentots, under different names, were once spread over the territory now called Cape Colony, and at the present day may be considered as generally within its limits, though they have been driven from the southern parts by the European colonists. They occupy, also, the basin of the Orange River. The Hottentot presents some varieties both in physical appearance and moral character; but in his lowest state he is one of the most indolent, helpless, and dirtiest of the human family: his form, though spoken of by some travellers as not positively ugly, would appear from the best accounts to be revolting to our ideas. His hair is black, sometimes brownish, very short, and woolly; his profile is hideous, and remarkable for the prominence of the lips, over which the nose is flattened, displaying the open nostrils; the foot is so singularly formed that he can be tracked by his marks. The colour of the skin is dark brownish, or yellowish, but not black. The Caffres differ both from the Hottentots and those whom we call negroes. The nose approaches to an arched form; yet they have thick lips, and hair curly, but less woolly than the negro. Their colour is a blackish grey; and they are generally well made and of rounded limb. The females are among the handsomest of the black race of Africa. In the useful arts of life, the Caffres are far above their Hottentot neighbours. They extend from Natal, on the southern coast of Africa, into the interior, probably as far as the tropic, but it is not possible to fix their limits with any precision.

The most widely-extended race in Africa is the Negro, which some writers denominate the Ethiopian. The term Ethiopian is indeed often used, but, as it appears to us, rather vaguely, to include all the black-coloured races of Africa. We here understand by it *only* the true negro races, which, whatever resemblance they may bear to the other dark races of Africa, still differ from them considerably in physical character and geographical distribution. Varieties of language, shades of complexion, or other differences certainly subsist among them, (and they are by no means inconsiderable;) but we must still recognize the whole Ethiopian race as forming a distinct and widely spread family. Beginning on the west coast with the Senegal River, which is the southern limit of the arid deserts and the commencement of the fertile regions, we find a race essentially different from those of Northern Africa. In the woolly hair, black skin, the profile of the face and forehead, the oblique insertion of the incisive teeth, the form of the pelvis, and the legs, we see the undoubted characteristics of a race peculiar to the African continent. But it is still difficult to say what parts of Africa must be considered as their proper country, as war and the slave trade have often transplanted the negro from his localities in Africa, just as they have given him a new home in Europe and America, and made his form and character familiar to our every-day experience. We may safely assume, that the negro is on his native soil in all the regions that extend from the Senegal southwards, along the gulf of Guinea, and south of the equator as far as the sixteenth degree of latitude. On the eastern side the negro race hardly extends south of the tropic, for they must not be confounded with the Caffres who dwell from Natal northward. The natives whom Mr. Salt saw as far north as Sofala bay near lat. 20°, he conceived to be nearly allied to the Caffres, whom he also considers to be a race 'perfectly distinct from either that of the Hottentot or of the negro.' We may, therefore, consider the Caffres as stretching nearly as far north as the Zambezi river, where the negroes commence. It is quite impossible to fix the limit between the Caffres and negroes in the interior. The latter may, perhaps, be considered the aboriginal inhabitants of the Mozambique coast, from that coast westwards into the interior: the Mackoua, whom Salt saw at Mozambique, are described by him as the most genuine thick-lipped negroes that he had ever seen; and the expeditions into the interior inform us that the people are negroes, though some of them are described as of a superior appearance and character to those on the coast. This may be attributed to the want of communication with the white man of Europe, who, wherever he has been allowed freely to settle himself, has, for the most part, destroyed or demoralized the people among whom he has come. We cannot at present state how far north on this coast the negro tribes extend, but certainly not beyond Cape Guardafui. The Somaulis of Adel are not negroes.

We know very little of the interior of Africa, south of the points to which Brown, and Denham, and Clapperton advanced; but we may reasonably conjecture these unknown regions to be occupied by black tribes, which indeed is proved to be true, for a considerable distance at least, by the negro slaves whom the traders bring to Dar-Fûr. The cultivable countries which commence south of the Sahara, and are watered by the Joliba and the various tributaries of Lake Tchad, are the region of the negroes, and known among the Arabs by the general name of Sudan or the country of the blacks. But we cannot say how far eastward the proper negro extends. The natives of Dar-Fûr (whose capital Cobbe is in 14° 11′ N. lat., 28° 8′ E. lon.) are described by Brown as having hair generally short and woolly, and a complexion for the most part perfectly black; yet he says they differ in their persons from the negroes of Guinea, and from the black and genuine negro slaves introduced among them by traders from the south and west. The negro races of the Nuba have, however, spread as far north and east as Sennaar, where a negro dynasty of the Fungi (conquerors) established itself in 1504, and has mingled itself with Arab blood, and adopted a Mohammedan creed. The Shangalla, who also belong to the Nuba, have spread eastward as far as the Tacazze and Mareb, and to the coast of the Red Sea. It is, however, not improbable that there were negro tribes on the upper waters of the Nile during the period of the Pharaohs. The negro is easily recognized in the procession in the tombs of the kings at Thebes. (See Belzoni's plates, and Burton's *Excerpta.*)

The desert of the Sahara, and the southern limits that border on Sudan, swarm with innumerable tribes, of whom the greatest number are included under the general name of Moors. They are a mixed race, and live a wandering life; they are not Arabs, but they have adopted the religion of Mohammed. They are found spread toward the regions of Fez and Marocco, towards the arid Atlantic coasts that bound the western Sahara, and their dominion is fixed on the stream of the Mid-Senegal and Mid-Joliba; they form in fact, a narrow belt or slip stretching from the Atlantic along the southern limits of the Sahara into the interior, probably as far as the Bahr el Abiad. The Tibboos are a wandering tribe, who conduct caravans from Fezzan to Bornou, and are considered by some to speak a kind of Berber dialect. But the most numerous and widely-spread race of the deserts are the Tuaricks, who possess the chief trading ports from Ghadamis eastward, through Fezzan, Augila, and Siwah. They are said to speak a Berber language, and to be mixed on the north with Arabs, on the east with Tibboos, and on the west with Berbers.

The mountain regions of the Atlas, which by their position and character hardly belong to the continent of Africa, as well as the whole shores of the Mediterranean from the straits of Gibraltar to the Cyrenaic regions, have been subject to the invasion of conquerors ever since the earliest periods of history. The Phœnician, Greek, and Roman, Vandals and Goths, and Arabs from Asia, have at different periods possessed portions of these regions, and mixed their blood with that of previous races. The Arab invasion has produced the most permanent effects, and that nation now occupies the most fertile parts of the Atlas region and the towns on the coast, and are generally known to us by the incorrect appellation of Moors; the subsequent conquests of the Turks (also an Asiatic race) have done little more than establish a despotic power on a few isolated spots, under a military chief. But it seems not unlikely that, after all these violent revolutions, the Berbers and Shelluhs of the Atlas mountains are the descendants of the primitive inhabitants, and that they retain their original language in all its substantial parts. It has been well remarked by Ritter, that as the Atlas regions differ in character from the rest of Africa, so its primitive inhabitants have a different character also; and, however, their language or usages may have changed during the lapse of many centuries, we can hardly doubt about assigning them to the wide-spread Arabic family, which there is good reason for considering indigenous in northern and north-eastern Africa as well as in the great Arabian Peninsula. The wide diffusion of this race, across the continent as far as the waters of the Nile and the Gulf of Aden, according to some opinions, will be examined more particularly under the head of BERBER, a term applied, we believe, with no great precision, by many writers on African ethnography. We reserve to the particular descriptions of each subdivision of Africa, a short notice of the political revolutions that have affected the physical and moral character of its present inhabitants, or we shall refer for such information to the best authorities. We need only remark, in order to complete this general sketch of man in Africa, that the ruling race of Amhara, and Tigre, who are included under the name of Abyssinians, must either belong to Arabic stock, or, if they be considered as a separate, they are still a nearly related family. But at present we cannot attempt to classify the various peoples who occupy the widely spread Abyssinian provinces; it is probable that they contain many varieties of the human species, the remnants of nations become extinct, or the result of the intermixture of different races. The Galla, whose invasions of Abyssinia from the south may be compared with the movements of the Nomadic tribes of Asia, have not yet been identified with any other nation, and must for the present be considered as a separate family. The Arab race which sometimes has mingled with negro and other races, now occupies a large part of the countries north of Abyssinia as far as the Mediterranean; but the population of the Nile basin is of a very motley character. The Copts, or descendants of the Egyptians, are reduced to a small number; and of all the conquerors or settlers in Egypt, none have stamped their physical and moral character so strongly on the country as the followers of the Prophet. The Arabs have carried their faith as far as Dar-Fûr, and even to the banks of the Tchad; and the Fellatah empire acknowledges the precepts of the Moslem faith. Even in Comassie, the capital of Ashantee, Arabic is taught. The Mohammedan religion has spread over at least one-third of the continent; and some of its precepts and practices seem well adapted to win the favour of the indolent and pleasure-loving negro. When the Portuguese commenced their settlements at Mozambique, they found the Arabs in quiet possession of the coast, and though they succeeded in killing them all, and getting possession of the navigation of the Zambezi river, yet as some of the sovereigns of the interior had at that time adopted Mohammedanism, it is not unlikely that this form of religion exists in these parts of Africa still unknown to us.

The only African countries where Christianity is now established, excepting the few European settlements, are Egypt and Abyssinia. In Egypt it is confined to the Copts, and in Abyssinia both its doctrines and precepts are as ill understood as they are obeyed.

The Arabic is the only character that is now used in Africa by those who wish to read and write, except those employed by the people of Tigre and Amhara. Its use is, however, limited to very few in Sudan, where it is only great doctors who can read and write.

The Jews, a nation now dispersed over almost every part of the world, are found also in the Samen of Abyssinia, in Egypt, and indeed scattered as far west as the kingdom of Marocco. They do not seem to have established themselves south of the Sahara.

The great island of Madagascar, yet so little known, is occupied on the west side by negroes, who have at various times furnished large supplies of slaves to the Cape of Good Hope and the Mauritius. Whether the negro is aboriginal in this island, we do not know. Madagascar at present is to a great extent occupied by a race of Malay stock, whose arrival in the island is not recorded by any historical document. Some Caffres are found on the south coast. Many Arabs also are found in Madagascar, particularly the northern part, of the period of whose arrival there we are entirely ignorant.

VI. ANIMALS OF AFRICA. In the animal kingdom, at least, Africa is as rich in the number of its peculiar species, (if they are not so remarkable for the singularity and anomalous forms which they exhibit,) as any other quarter of the globe. The peculiar difficulties which have at all times opposed the progress of European discovery in this part of the world, have hitherto prevented us from acquiring so satisfactory a knowledge of its zoology as could be wished; but enough is already known to enable us to form a general idea of its productions, and to infer, with a tolerable degree of accuracy, their most prominent features and characters.

Of three hundred different species of mammals which are known to be inhabitants of Africa, upwards of two hundred and fifty are peculiar to that continent and the neighbouring island of Madagascar; and of these a vast majority are to be found only to the south of the great desert. The following table exhibits the relative numbers of the species of African mammals belonging to each of the orders of the Cuvierian system, compared with the whole number of species belonging to the particular order, and it distinguishes those which are peculiar to Africa from those which are common to it and other continents.

ORDERS.	Whole No. of known species.	Whole No. of African species.	No. of species peculiar to Africa.	No. of species common to Africa and other Continents.
I. Quadrumana (Apes, Monkeys and Lemurs) . .	186	55	48	7
II. Cheiroptera (Bats) . .	192	30	26	4
III. Carnivora (Carnivorous Mammals)	320	66	52	14
IV. Rodentia (Gnawing Mammals)	295	48	38	10
V. Edentata (Sloths, Anteaters, &c.)	23	3	3	0
VI. Pachydermata (Hog, Horse, Elephant, &c.) . .	30	15	12	3
VII. Ruminantia (Ruminating Mammals) . .	157	73	63	10
VIII. Cetacea (Whales) . .	76	10	8	2

An inspection of this table will at once show the relative number of species in each order, as well those which are proper to Africa alone, as those which are common to that and the adjoining continents of Europe and Asia. It will be remarked among other things, that Africa is richest in the number of its pachydermatous and ruminating animals, and most deficient in the number of its rodentia and edentata, compared with the whole number of known species belonging to each of these several orders; though it must be observed in regard to the rodentia in particular, that we have at present but a very imperfect knowledge of the African species, as well from their diminutive size and timid character which cause them to be less frequently met with than larger and bolder animals, as from the danger and difficulty which have nearly always attended scientific researches of all descriptions among the Arab and Negro nations. This remark with respect to the great abundance of pachydermatous and ruminating animals in Africa will not be considered devoid of importance, if we reflect that it is principally from these two orders of mammals that the animal food, not only of man, but likewise of the lower tribes of carnivorous animals, is derived. We proceed to give a brief sketch of the most remarkable species of African animals.

The quadrupeds of burden are highly valuable. The Arabian camel (*Camelus dromedarius*) is now spread over all the northern and central parts of the continent, and is indispensably requisite in crossing the long arid deserts which cover so great a portion of its surface north of the equator. Some writers suppose that the camel was not indigenous in Africa, but we have no historical account of its introduction into this continent. It is mentioned in the book of Genesis, as being used by the merchants who traded to Egypt, and of course must have been well known at that period on the banks of the Nile. The head of the camel is found on obelisks and other ancient Egyptian monuments from the city of Alexandria as far south as 18° 25′ of N. latitude. Camels' heads are cut on the plinth of one of the two granite lions which Lord Prudhoe brought from Jebel Barkal in Dongola, in 1832. As to the horse, it is spoken of in the Bible, and is represented on some of the oldest specimens of Egyptian sculpture; but we cannot assert that it is indigenous in Africa, nor on the other hand can we mention any period at which it was introduced. Leo Africanus relates that there are wild horses to be met with in Africa, but this report has not been confirmed by any modern traveller, and there is strong reason to doubt its truth. However this may be, it is certain that the soil and climate of Africa are peculiarly adapted to develope the physical and mental qualities of these quadrupeds. The horses and asses of Barbary, those of the Bedoweens and of Egypt, yield in no respect to the finest Arabs either in beauty of form or spirit. The first of these races was introduced into Spain during the ascendancy of the Moorish power in that country, and from it the noble Spanish breed of modern times is descended.

Of horned cattle there are a great many different varieties in Africa. The most remarkable are the Sanga or Galla oxen of Abyssinia, with immense horns nearly four feet in length, and a kindred race in Bornou, the horns of which measure upwards of two feet in circumference at the base, and yet scarcely weigh two pounds a-piece. Of sheep, the most remarkable varieties are the broad-tailed kind, whose tails grow so fat and heavy that, according to Shaw's report, they are frequently obliged to be supported on little wheel-carriages, as Herodotus says of the Arabian sheep. This variety is common in Barbary, at the Cape of Good Hope, and in other parts of Africa. The edimain, a very tall variety, with long legs, small tails, and drooping ears, is common in Egypt, Sennaar, and Nubia. Both these breeds are covered with short coarse hair instead of wool, and their flesh is very inferior in quality to our European mutton. Goats are in many parts of Africa more common than sheep, as they subsist better on the dry aromatic herbs of the desert, yield a more abundant supply of milk, and are generally preferred for the table. Of these also there are many different varieties; among others, a dwarf species, with short smooth hair and very small horns, which has been introduced into South America, where it has multiplied prodigiously.

The domestic cat is very rare in Africa, but dogs are numerous, and of many different varieties. Among the Mohammedans, it is well known that these animals are considered unclean; but though they refrain from keeping them in their houses, all the large towns of Egypt and Barbary maintain public troops of dogs, which perform the offices of common scavengers, establish themselves in particular quarters of the city, maintain a kind of government among themselves, and are extremely watchful to prevent strangers from intruding into their particular districts. It is no uncommon thing for the wealthy Mussulmans to leave considerable legacies for the support of these animals; and it is very remarkable, that notwithstanding the great heat of the climate, and the constant scarcity of water, an instance of canine madness is never known to occur in Africa.

Domestic poultry are common enough in every part of Africa, though they also are of foreign introduction. Every one has heard of the artificial mode of hatching chickens which has been so long practised by the Egyptians, and of which an exhibition on an extensive scale was some years since afforded to the inhabitants and visiters of this metropolis. Turkeys have, of late years, been introduced about the neighbourhood of Sierra Leone, but they have not yet become numerous, and, perhaps, the country is not well adapted to their habits. It does not appear that the Guinea hen, though indigenous to Africa, is at present domesticated among the inhabitants: in Dar-Fûr, the Guinea fowl is indigenous. Geese and ducks are not extensively distributed, and even where they are found, are reared in small numbers, and held in very slight estimation. Probably, the extreme dryness of the climate may have a considerable influence in depreciating the utility of these birds.

Among the wild animals of Africa the first and most remarkable is the chimpanzee or pongo, the *simia troglodytes* of naturalists. This extraordinary animal, of which there is good reason to believe that more than one variety exists in Africa, approaches much nearer to the human form than the orang outang, or wild man of Borneo Sumatra, and the other large islands of the Indian Archipelago. Its arms are not so disproportionately long as in that animal; its neck is not so short and deformed, nor are its shoulders so high; and it has altogether a much greater facility of standing and walking upright, and of using the anterior extremities as hands, properly speaking. Its organization, however, determines its general habit of walking on all fours; and the hinder extremities are, as in all the order, marked by a thumb—a finger opposed to the other fingers. The adult chimpanzee has never been brought into Europe. Of the inferior tribes of quadrumanous animals, the greater number of the cynocephali, or baboons, are found only among the rocks and mountains of Africa. Many of these, such as the mandril (*Cynocephalus maimon*) and the tartarin (*Cyno. hamadryas*), attain a very considerable stature, and, from their great strength and malicious disposition, are much dreaded by the negroes. The monkeys, properly so called, (*Cercopitheci*,) are likewise an African genus. These playful and harmless little animals, of which there are a great many different varieties, many of them marked with the most brilliant and varied colours, swarm over the whole continent, living in large troops and enlivening the woods with their gambols and chattering. All the various and beautiful species of lemurs also, the tardier and slow lemurs *(nycticebi)* alone excepted, belong either to the continent of Africa or to the neighbouring island of Madagascar. In the latter country, so completely insulated from the rest of the world, and of which the natural productions are, for the most part, singular and anomalous, the different species and varieties of lemurs are extremely numerous, and even entirely replace the apes, baboons, and monkeys of the adjacent continent, none of which, as far as we are at present aware, have ever been found in this island.

The cheiroptera, bats, or winged mammals of Africa, are not so well known as some of the other tribes, though it is probable, from the physical nature of the country and climate, that they are quite as various and abundant here as in Asia and America. Of those which we do know, the most remarkable is the common roussette *(Pteropus vulgaris)*, which inhabits Madagascar and the Isle of France, grows to the size of a small fowl, feeds on fruits, and is eaten by the inhabitants, who compare its flesh to that of the pheasant and partridge.

Carnivorous and ferocious animals are extremely numerous in all parts of Africa. The lion, the panther, and the leopard, lurk in the vicinity of the rivers and fountains to surprise the different species of gazelles and antelopes, but, unless pressed by hunger, rarely attack the inhabitants; though it is said that the lion will often pursue the Hottentot in preference to all other prey. In some parts, however, these animals are so numerous, that the natives will not venture to travel through the woods unless in large parties and well armed. Major Laing informs us, in his journey to the Soolima countries, that he passed through a country which had formerly been well inhabited, but in which, at the period of his visit, there was not a single village to be met with for a space of twenty-five miles along his path, the former populousness of the country being alone indicated by the sites and ruins of several large towns: the inhabitants of these had been forced to remove to other provinces on account of the great numbers and constant attacks of the leopards and panthers. The whole genus of hyænas are, properly speaking, African animals. The common hyæna, indeed, (*Hyæna vulgaris*,) is likewise found in India; but the other two known species (*Hyæna crocuta et villosa*) are found only in the peninsula of Africa. Besides these, there is another animal described by Mr. Burchell, in his *Travels in Southern Africa*, which is intermediate in its habits and organization between the hyæna and the dog, and which has been associated with both these genera under the names of *hyæna venatica* and *canis picta*. All these different species of hyæna live entirely upon offal and carrion, and are of singular importance in the economy of nature, by preventing the accumulation of putrescent matter, and devouring dead carcasses and other garbage, which, under the influence of a tropical sun, would soon corrupt and produce the most noxious and unwholesome vapours. Like feline animals, the hyænas are nocturnal, and nightly visit the towns and villages, where they prowl through the streets till morning, eating the garbage and off-castings of the shambles, and devouring any tame animal which the inhabitants may have neglected to secure. The true civet (*Viverra civetta*) is found in a state of nature in most parts of Africa. Great numbers of these animals are kept by the natives for the sake of their perfume. Nearly allied to the civets are the animals which naturalists call ichneumons (*Herpestes*), of which Africa contains four or five distinct species, and which wage incessant war against the numerous serpents and other reptiles which infest every part of the country. As far as our present information extends, there are no bears in Africa. The older African travellers, indeed, often mention having had their dromedaries and mules bitten by bears during their night encampments, but their relations are always to be understood of the hyæna, which is usually called a bear in the north of Africa, as he is called a wolf in the south.

Of the Rodent mammals (*Rodentia*) of Africa, it has been already observed that we have no very extensive knowledge. Two or three varieties of hares, differing little from our common European species, are found throughout every part of the continent; and the common rabbit, which is now so abundant in all the temperate countries of Europe, is said to have been originally introduced from Barbary. Eight or ten distinct species of jerboas (*Dipus*) inhabit the desert, where they burrow among the loose sand, and feed upon different bulbous roots, which in certain situations are very abundant. Beautifully-variegated squirrels inhabit the woods, and rats and mice, of many different species, are as numerous as in other countries. Among the latter, one species in particular, the Barbary mouse (*Mus Barbarus*), is remarkable for the beauty of its colours, being marked on the back with ten longitudinal white lines; and another (*Arvicola pumilio*), having four black stripes along the back, is thought to be the smallest of all quadrupeds, weighing, according to Professor Sparrman, not more than four scruples.

Though South America is the chief residence of Edentalous mammals, two species are nevertheless found in Africa. These are the aardvark (*Orycteropus Capensis*) and the long-tailed manis (*Manis Africana*). Both feed upon ants, and burrow beneath the surface of the earth; the latter is totally deprived of teeth, but its body is defended in every part by a thick covering of hard, trenchant scales, which protect it, like a coat of mail, from the assaults of its enemies. It has likewise the faculty of rolling itself up into a round ball like a hedgehog; and in this position it is safe even from the teeth and claws of the lion and panther.

The elephant necessarily occupies the first rank among the wild hoofed quadrupeds of Africa. The African elephant, though long confounded with the Asiatic, is now well known to be a distinct species; its forehead is more convex, its ears larger, the markings of its molar teeth are of a different form, and it has only four hoofs on the fore feet and three on the hind, whilst the Indian species has five before and four behind. In magnitude, intelligence, and docility, however, it does not yield to its Asiatic congener; and if we were to credit the exaggerated statements of travellers, it would even appear that the African elephant occasionally attains the height of seventeen or eighteen feet. However this may be, it is at least certain that the tusks of ivory imported from the coast of Guinea are considerably larger than those which are obtained from India—often weighing from one hundred and fifty to one hundred and eighty pounds, whilst the latter rarely exceed one hundred or one hundred and twenty pounds. These animals inhabit all the woody parts of Africa south of the Sahara, and are found in Dar-Fûr: they live in immense herds of from one hundred and fifty to two hundred individuals; and are said to be so numerous throughout the whole extent of middle and southern Africa, that we could scarcely credit the reports of travellers, were they not confirmed by the immense quantities of ivory annually imported into Europe from the western coast of Africa alone. A considerable quantity of this ivory is said to be found in the woods, being either broken by the animals in their combats with one another, or in their attempts to uproot different kinds of trees for the purpose of feeding upon their roots and branches; but much the greater part of it is the produce of the chase, whole tribes often devoting themselves to this employment. Various modes of capturing this huge animal are resorted to by different tribes. Major Laing informs us that the inhabitants of Soolimana attack him in the open field, and kill him with a spear having an iron head, formed like an equilateral triangle, and fired from a long Danish gun. The colonists of the Cape of Good Hope attack this animal, as well as the rhinoceros and hippopotamus, with simple fire-arms, only mixing a little tin with the lead, for the purpose of hardening their balls, and preventing them from flattening against the tough hides of these beasts; and it is no uncommon thing for the expert and experienced hunters to bring down their game at a single shot. Among the Shangalla, Bruce informs us that the elephant is attacked by two men mounted on the same horse, who ride round the beast till the hindmost hunter gets an opportunity of suddenly and secretly dropping down behind him, when, with a single stroke of a sharp double-edged sabre, he severs the tendon Achilles immediately above the heel; and by this means so completely disables him, that the hunters can afterwards despatch him at their leisure. During these hunting expeditions, which often last three or four months, the hunters live entirely upon the flesh of the slain elephants, and frequently collect as much ivory as enables them to live in what they consider affluent circumstances for two or three years afterwards. The African elephant is not now, as far as we know, employed in the service of man; though the Ptolemies undoubtedly obtained elephants of war from Ethiopia. In the sixth century, Cosmas says that the Ethiopians could no longer train them for war [see Adule].

Of the rhinoceros, one species at least, and probably more, inhabits the middle and southern parts of Africa, frequenting the same localities as the elephant, and hunted as ardently by the people, though his hide and horns are the only part of him that can be turned to account. Of this shields are made in some parts, and in others traces and harness; for all of which purposes its great thickness and durability render it extremely appropriate. The African rhinoceros, like that of Sumatra, has two horns, but it is distinguished from the latter species by having no front or incisor teeth. The horns, as in the East, are highly esteemed for their supposed medicinal virtues.

The hippopotamus is found in the large rivers and lakes of Africa south of the Great Desert; and from being less hunted and more difficult to come at than either the elephant or rhinoceros, is in many parts extremely common. This animal appears to have kept possession of the fresh-water lakes and rivers of Africa, and to have inhabited the very same localities which he now occupies from the earliest ages. The Greek and Roman writers frequently mention him as an inhabitant of the Nile; and Hanno, the Carthaginian Admiral, in his voyage along the western coast of Africa, informs us that he came to a large river—which, it is supposed, must have been either the Senegal or the Gambia, or the Rio Grande—in which the hippopotami were very numerous. At the present day the hippopotamus is never seen below the second, and perhaps not below the third cataract of the Nile; but on the opposite coasts of the continent, in the Senegal, the Gambia, and the Niger, they are numerous, and extend southward as far as the Cape. Within the boundaries of the latter colony, indeed, this animal is at the present day rarely met with; but it was formerly as abundant as in other parts of Africa, and still exists on the northern and eastern frontiers.

The engallo or wild boar of Africa (*Phascochœros*) is a very different species from that of Europe, though the latter is likewise said to be found in Egypt and Barbary, as it certainly is in India and other parts of the East. The engallo is, perhaps, the most hideous of all mammals in appearance. It resembles the elephant in the form and structure of its molar teeth. Of these there are never more than two in each jaw; they are not renewed as in ordinary quadrupeds by the new one growing under the old, and gradually pushing it out of the socket; but the young tooth is formed in this case behind the old one, and gradually advances forward and assumes its situation, as the latter is worn down by constant use.

The zebra, the dow, and the quagga (*Equus Zebra, duplivirgatus, and quaccha*) are found in most parts of southern and central Africa which are known. These beautiful animals, equally remarkable for the symmetry of their forms, the rapidity of their course, and the brilliancy and wonderful regularity of their colours and markings, associate in large herds upon the open plains and gentle declivities, and are the frequent prey of the lion, which is said to prefer their flesh to the dry and tough venison of the various species of gazelles and antelopes that inhabit the same localities. It has been repeatedly remarked by African travellers, that these animals and the ostriches seem to have a natural predilection for each other's society, and that the flocks and herds of these very different species are constantly found intermixed, though they refuse to associate with other animals. It is not a little remarkable, that the same was observed by Xenophon, during the expedition of the ten thousand Greeks, with respect to the ostrich and quagga or wild ass, on the plains of Syria and Mesopotamia. The fact may probably be accounted for by the mutual security which each feels in the other's company, the long and flexible neck of the ostrich enabling it to take notice of the most distant appearance of danger, and the well-known courage of the wild ass compelling beasts of prey to respect their quarters. It is to be lamented that no judicious attempts have ever been made to domesticate these beautiful animals.

Among ruminating animals, Africa is chiefly remarkable for the immense numbers of different species of antelopes which it contains; no fewer than sixty species, out of eighty which have been enumerated in this extensive genus, being proper to that continent. This is a very peculiar feature in the zoological character of Africa, especially when we consider that there have been only two species of deer (one of which is our common fallow deer, which has been ascertained to be indigenous to North Africa) hitherto discovered throughout the whole extent of the continent. Asia, on the contrary, whilst it abounds in many different species of deer, contains, comparatively, very few antelopes, being thus completely opposed, in an important zoological feature, to the neighbouring continent. For a more detailed account of the habits and external characters of these animals, see *Antelope*. Of other wild ruminating animals indigenous to Africa, the most remarkable is the giraffe or camelopard, which is found from the banks of the Gariep to the southern borders of the Great Desert. Two or three wild species of buffalo also inhabit the woods and marshy grounds of the interior, but we know little of their forms or habits. The bos caffer, or wild buffalo of the Cape, has the base of the horns extending all over the top of the head and forehead, in the manner of a helmet; he is a savage, dangerous animal, and much dreaded by travellers.

Among the cetaceous mammals which inhabit the seas and coasts of Africa, we need only mention the lamantin, (*manatus Senegalensis*,) which frequents the mouths of the great rivers on the Atlantic and Indian Ocean, and feeds upon the aquatic plants that it can reach along the shores. It was this animal which, from the pectoral situation of its mammæ, and from the habit of raising itself half out of the water, especially when in the act of suckling its young, gave origin to the fable of the mermaid, by which name it is often mentioned by ancient African voyagers and travellers.

Of the ornithology of Africa, we cannot undertake to give more than a very general account. Indeed, from the physical conformation of birds, they are not so confined and limited in their geographical distribution as quadrupeds; and, consequently, the ornithology of particular countries is never so peculiar nor exclusive as its mammalogy. Birds, possessing powers of locomotion which quadrupeds want, often migrate to the most distant climates. Thus many of our European species, such as the common quail, the land-rail, the cuckoo, and the different varieties of swallows which spend the summer and autumn in northern climates, migrate for the winter season to Africa; and others of our common species are found distributed over the whole eastern hemisphere without presenting any sensible difference, even in the colour of a feather, in the most remote localities. The ostrich has already been incidentally mentioned as an inhabitant of Africa. At the present day, indeed, it would appear to be exclusively confined to that continent, though in the age of Aristotle and Xenophon it was found in the deserts of Syria and Mesopotamia. Captain Lyon informed us that the best ostrich feathers imported from Barbary are not procured from the wild birds of the desert, but from semi-domesticated individuals which the Arabs take young and breed up in stables, where they are well supplied with soft bedding to prevent them from wearing or injuring the feathers. Similar to the ostrich in many of their habits, and even somewhat in appearance, are the bustards, many different species of which inhabit the Karroos and arid plains of Africa. Of gallinaceous fowls, adapted to the poultry-yard, Africa possesses but a single genus, the Guinea-hens, (*numida*,) which, however, are found in no other part of the world. These birds, of which there are three or four distinct species, go in large flocks of 400 or 500, and are most frequently found among underwood in the vicinity of ponds and rivers. There are, besides, many species of partridges and grouse in different parts of Africa; but as these are not fitted for domestic purposes, and have otherwise nothing remarkable in their habits or economy, it will be sufficient at present to indicate them thus generally. Wild fowl of various species are also abundant on the lakes and rivers, as are likewise various species of owls, falcons, and vultures, the latter of which, like the hyænas among the quadrupeds, are highly useful in consuming the offal and carrion which might otherwise taint the air and produce disease. The exquisite sense of smell possessed by these birds is truly surprising. One of the most remarkable and useful birds of prey peculiar to Africa is the secretary (*serpentarius*), which may be not improperly described as an eagle mounted on the long naked legs of a crane. This bird preys exclusively upon serpents, which it pursues on foot, and destroys in amazing numbers.

Among the smaller birds of Africa are many species remarkable for the gaudiness and brilliancy of their plumage, or the singularity of their manners and economy. Of the former kind may be mentioned the innumerable varieties of parrots and parroquets, which, from the size of a sparrow upwards to that of a raven, swarm in all the forests, and make the woods resound with their hoarse unmusical screams. Of the latter kind, it will be sufficient to mention the honey cuckoo (*cuculus indicator, Lin.*) and the little bird called the republican (*loxia socia, Lath*).

Lizards, serpents, and other reptiles abound in every part of Africa. The crocodile inhabits all the large rivers of the tropical parts, and is still abundant in the Nile below the first cataract; different species of chameleons may be seen on every hedge or shrub; and the enormous python, a serpent of thirty feet long, lurks in the fens and morasses. Among the venomous species, the dipsas, the asp, and the cerastes, or horned viper, are frequently mentioned by the ancient classical writers; whilst the garter snake, the puff adder, and other species, are at present employed to poison their arrows by the Bosjesmans, the only African tribe who use this deadly and cowardly weapon.

Of the insect tribes, Africa also contains many thousand different kinds. The locust has been from time immemorial the proverbial scourge of the whole continent; scorpions, scarcely less to be dreaded than the noxious serpents, are everywhere abundant; and the zebub or fly, one of the instruments employed by the Almighty to punish the Egyptians of old, is still the plague of the low and cultivated districts. For a particular account of the ravages of this dreadful insect, the reader is referred to Bruce's *Travels*, (4to. edit.) vol. i. p. 388, and *Appendix*, p. 188, where there is also a good figure.

VII. PLANTS OF AFRICA. The nature of African vegetation will be best understood by tracing geographically the changes it undergoes between a state but little different from that of the south of Europe, and the singular Flora of the Cape of Good Hope. To the traveller who passes from the south of Europe to Tangier, the appearance of the African coast presents nothing remarkably different from what he has left in Europe; and along the whole of the most northern shores so great a similarity continues to be preserved, that if it were not for a few striking objects, he might fancy himself still in Spain or in France. Groves of oranges and of olives; wide plains covered with wheat and barley; thick woods of evergreen oaks, cork trees, and sea pines *(Pinus maritima)*, intermixed with cypresses, myrtles, arbutus, and fragrant tree heaths *(Erica arborea)*, form the principal features of the landscape; while the plains are covered with the gum cistus, and the hills and rocks with odoriferous rock-roses, palmetto trees, and the wild caper. In January and the early months of the year, when the climate is like that of the warm days of our spring, the plains are green with grass, and embellished with innumerable little flowers of the monocotyledonous class, and the gardens are gay with the blossoms of the almond, the apricot, and the peach. Even in the summer season, when all the more delicate plants have been dried up beneath a scorching sun, there is still the oleander, with its brilliant bunches of rosy flowers, by which are traced from afar the courses of the rivers on the banks of which it loves to dwell, and those humid spots which, from accidental circumstances, being never dried up, are then a kind of vegetable oases. On this northern coast the date palm is first found; but its fruit does not arrive at perfection, and it is chiefly valued as an object of ornament to gardens and houses.

The principal objects of cultivation in the Barbary States are a kind of wheat, *(Triticum durum,)* the stems of which are solid, and the grain horny rather than farinaceous; barley which the Moors give their horses instead of oats, maize, caffre corn, *(Holcus sorghum,)* rice, tobacco, olives, oranges, and figs of the most delicious quality; pomegranates, grapes, and jujubes, together with sweet melons and water melons. They also grow the white mulberry for silkworms, a kind of indigo, *(Indigofera glauca,)* cotton, sugar-cane, and most European esculent vegetables. It is in the mountainous country, south of the Barbary States, in the chain of Atlas, that grows that famous timber *(Thuja articulata)* called, from the substance it produces, the sandarach tree, which is almost imperishable, from which the ceilings of the mosques are exclusively constructed, and which is supposed to have been the shittim wood of Scripture.

As soon as the chain of Atlas is passed, the scene begins to change; the excessive dryness of the climate on the northern borders of the Great Desert is such, that few trees, except the date, can maintain an existence. It is, however, in this arid region, where rain seldom falls, where wheat refuses to grow, and even maize, barley, and caffre corn, afford the husbandman a miserable and uncertain crop—where the blasts from the south are scarcely supportable by the native himself, that this invaluable gift of Providence finds its fitting station. It is here that the groves of date palms form a screen impervious to the rays of the sun, and cherish beneath their shade, the orange, the lemon, the pomegranate, and the vine, the latter of which climbs to the summit of their trunks by means of its twisted tendrils. Although reared in constant shade, all these fruits acquire a more delicious flavour than in what would seem a more favourable climate.

Egypt exhibits a scene intermediate, as it were, between the first and the last of these descriptions; but also presenting more the appearance of a tropical country. European plants begin to disappear; in the districts still watered by the Nile, we find all the richness of vegetation of the spring months of Barbary; abundance of rice, barley, and wheat; rich fields of sugar-canes; olives, figs, vines, and plantains that have been introduced; while in the hotter or drier, or more southern, the date is the chief object of the scenery. Nothing but stunted and miserable looking bushes are able in the open plains to contend with the accumulating sand for the possession of the soil. In the richer parts of the country we find the acacias which produce gum arabic, large tamarisk trees, called atlé, great quantities of the senna plant *(Cassia obtusifolia* and other species), intermixed with various herbs belonging to tropical genera, all of which are either unknown or very rare in the more northern parts of Africa. Cotton, coffee, indigo, and tobacco are cultivated with the greatest success. At Thebes first begins to appear a third race of palms different from the date and the palmetto; viz., the forky-branched doom palm *(Cucifera Thebaica)* of Upper Egypt, which is most remarkable as being almost the only species in the whole palm tribe in which the stem is not perfectly simple and unbranched; and in Abyssinia are first found species of the ginger tribe (*Scitamineæ*), in the form of cardamoms, which afterwards become a feature of African vegetation within the tropics.

The deserts that occupy the interior of this continent, like inland oceans of sand, are scarcely inhabited by any plants except of the most stunted character; one of the most remarkable is a grass called kasheia *(Pennisetum dichotomum)*, which wholly covers immense districts, and is said to cause intolerable annoyance to the traveller by its prickly involucrum; another is the agoul *(Alhagi maurosum)*, which furnishes a grateful food for the camel.

In the equinoctial parts of Africa all trees of European vegetation, and even the date tree itself, disappear; where moisture exists in sufficient abundance to favour vegetation, the flora partakes in a certain degree, particularly on the east side, of the plants of India, but is to a much greater extent composed of species peculiar to itself. The landscape is characterized by masses of the unwieldy Baobab (*Adansonia*), the fruit of which affords the natives a grateful drink, huge cotton trees (*Bombax pentandrum*), the trunks of which project at the base into great buttresses, shrubs of richest verdure, large gramineous plants with branching stems, impenetrable thickets extending into the water, with thick groups of oil palms (*Elais Guineensis*), sago palms (*Sagus raphia*), and others of the same majestic tribe. In the thickets numbers of combreta, of bindweeds, and of other climbers twine among the branches of the trees, which they adorn with flowers of white, or scarlet, or orange. On the branches of the forest trees grow sparingly various genera of epiphytes; the laburnum of the colonists (*Cathartocarpus fistula*) expands its branches of golden flowers, and replaces the senna of Alexandria; in some places the woods abound in pine-apples, which, although not natives of the continent, have established themselves as completely as in their native stations in tropical America; the plains are often covered with immense quantities of the papyrus plant, to the exclusion of all others; and in the regions near the line a new feature is introduced by the chandelier tree (*Pandanus candelabrum*), which rises singly in the plains, and divides its grotesque branches into repeated forks, the extremities of which are crowned with long, rigid, channelled leaves, like those of the pine-apple.

With the general nature of the vegetation change also the species that are cultivated for the food of man. In the tropical regions of Africa, no waving fields of corn reward the labours of the husbandman; the vine is unknown, the figs are of other and of useless species, and of all the northern fruits the orange and the lime alone remain. In their stead the cassava (*Iatropha manihot*), the yam (*Dioscorea*), the pigeon pea (*Cytisus cajan*), and the ground-nut (*Arachis hypogæa*) are the farinaceous plants; the papaw (*Carica papaya*), the tamarind, and the nitta or doura tree (*Parkia Africana*), are the fruits in some places; the Senegal custard apple (*Anona Senegalensis*), the grey plum (*Parinarium*), and the Safu, in others; and the bread fruit of Polynesia is represented by a large tree called musanga, the seeds of which are as agreeable as hazelnuts. Besides these, we have in Sierra Leone and along the same coast, the remarkable cream fruit, which, although of a most poisonous family, yields a wholesome and pleasant saccharine juice; the water-vine (*Tetracera potatoria*), the stems of which are a sort of vegetable fountain, discharging, when cut across, a cool, limpid, and refreshing fluid; the negro peach (*Sarcocephalus Africanus*), a brown succulent fruit, said to taste like a strawberry; the monkey apple (*Anisophyllea laurina*), the drupe of which is, in flavour and size, between a nectarine and a plum; and various species of pigeon plums (*Chrysobalanus*), together with the mammee apple (*Mammea Africana*), pishamins (*Carpodinus*), and star-apples (*Chrysophyllum obovatum*).

As we approach the southern point of this continent, a new change passes over the face of nature; tropical forms disappear as they have formerly appeared, and we lose the scenery of the cotton tree, the baobab, the palm, and the chandelier tree; not however to find their places occupied by the plants of Barbary and the north, but to contemplate an order of vegetable beings so different, that their very genera had been previously unseen: still the same wilderness of sand and drought occupies the centre of the country, but it is no longer covered with prickly grasses or waving thickets of papyrus. The karroos of the Cape Colony are the residence of fleshy, leafless, distorted, shapeless tribes of Stapelias, of Mesembryanthemums, Euphorbias, Crassulas, Aloes, and other succulent plants, each holding to the soil by the weak support of a single, wiry root, and feeding rather upon the dews of heaven than the moisture of the soil,—a situation to which they are admirably adapted by the want or imperfect state of their evaporating pores, so that whatever humidity they are able to collect is parted with as slowly as the limited supply is furnished to them. Among these grow stunted bushes of endless species of heath (*Erica*), and succulent geraniums (*Pelargonium*), strong-scented Bucku plants (*Diosma*), and a great variety of shrubby *Compositæ*. The hills and rocks are scattered over with a remarkable tribe of plants called Cycadeæ, intermediate, as it were, between ferns and palms; the plains are permanently clothed with patches of a rush-like plant called *Restio;* while the whole country, after the rains, teems with the fugitive but lovely blossoms of the *Ixia*, the *Gladiolus*, the *Disa*, the *Satyrium*, and the *Oxalis*. Plants of the Protea tribe also, of which there are very many species, for the first time appear since the country of Abyssinia, and under the name of Witteboom (*Protea argentea*) supply the inhabitants of Cape Town with fuel.

At Cape Town itself has been introduced the American aloe, which, with its spiny rigid leaves of six feet in length, forms impenetrable hedges, more resembling chevaux-de-frise than any living barrier; and the oaks and stone-pines of Europe have found a congenial climate.

Such are the more prominent features of the vegetation of Africa. Its islands partake more or less of the nature of the flora of the adjacent continent, modified chiefly on the west side by the cooling breezes of the Atlantic, and on the east by the wide expanse of the Indian and southern oceans. In these spots we have usually a total absence of African sterility, in consequence of their insular position; and from their luxuriant vegetation we may judge what that of Africa would be if either nature or the skill of man could succeed in conducting rivers and streams where there are now only barrenness and drought.

VIII. The following view of the great divisions of Africa, according to our present incomplete knowledge, will show under what particular heads further information will be found. This division is one of convenience, and may be liable to objections, but it is impossible to attempt, in a limited space, any complete division of Africa.

1. The region from the Orange river southwards, comprehending the CAPE COLONY, its mountains, elevated plains, European settlements, and native population; and extending eastward to the Great Fish River.

2. The eastern coast of Africa, from the Great Fish River to the neighbourhood of the Portuguese settlements, near Da Lagoa bay; comprehending the sea-coast occupied by the CAFFRES, or NATAL. In the interior the Caffre race is widely diffused in the high table-land, and has been found also, occasionally, on the coast as far as Quiloa.

3. From Da Lagoa bay to Cape Guardafui, the northern part of which coast is very little known; comprehending SOFALA, the settlements on the ZAMBEZI river, MOZAMBIQUE, and the native tribes of the coast and the interior, as far as they are known. From the neighbourhood of Cape Delgado north, we find the names of ZANGUEBAR and AJAN; the last-named coast terminating at the great eastern cape.

4. The ABYSSINIAN countries, with which may be grouped the almost unknown regions that border on them to the south; with the Galla, the Somaulis, Danakil, and other tribes, as far north as Masuah on the Red Sea [see ADEL].

5. The country of the BAHR-EL-ABIAD, or great western branch of the Nile, and the countries north of Abyssinia, comprehending the Nile Valley and the eastern deserts, between the Nile and the Red Sea. DARFUR and KORDOFAN may be most conveniently arranged in this division. Darfur is connected by some geographers with eastern Soudan. SENNAAR, DONGOLA, NUBIA, and EGYPT, belong to this division. The term NUBIA, since the conquests of Mohammed Ali, is sometimes used as a general name to comprehend all the countries south of the first Nile cataracts, which are subject to the Pacha. The BEJAS, BISHAREEN, ABABDES, and other tribes belong to this division.

6. The region west of Egypt, known to the Arabs by the general name of Maghreb, or the *West*, and extending to the extremity of the Atlas chain, comprehends the great political divisions of TRIPOLI, including BARCA, TUNIS, ALGIERS, and MAROCCO. This extensive region is often included by Europeans in the general term of BARBARY.

The chief OASES westward from Fezzan may be classed under this head, and placed in the division of BELAD-EL-JERID, or *Land of Dates*, according to some interpretations.

7. The SAHARA, or the great desert; with some of the oases.

8. SOUDAN or Central NIGRITIA, comprehending the regions watered by the Quorra and its tributaries, and by the tributaries to the Lake Tchad.

9. As a subdivision of No. 8, we may reckon the coast from the Senegal to the outlets and delta of the Quorra, including the countries watered by the Senegal, Gambia, Rio Grande, &c. &c., and the coast of Guinea, with the states in the interior. A name is wanting for this division: we shall use that of Western NIGRITIA, under which the subdivisions of this region, as far as they are known, will be given. The term of Senegambia was once in use, to signify the country from the Senegal to the neighbourhood of Sierra Leone.

10. The region from the Bight of Biafra to Cape Negro, which may be named Southern NIGRITIA, comprehending a long line of coast little known, and an interior still less explored. The names of LOANGO, CONGO, ANGOLA, and BENGUELA, are the chief great divisions hitherto adopted by those who have described this region.

These divisions of NIGRITIA, which are here adopted for the sake of convenience, are those of Balbi in his *Abrégé de Géographie*, except that he makes a fresh division of the Guinea coast, which comprehends the two great states of

Ashantee, Dahomey, &c., and calls it by the name of Maritime-Nigritia.

The African islands, not immediately bordering on the coast, consist of the following chief groups, or single islands.

North Atlantic Ocean.

The Madeiras—Archipelago of the Canaries—the ten Cape Verde Islands—Islands in the Bight of Biafra; Fernando Po, Prince's Island, St. Thomas, Anno Bom, &c. —The nine Azores, or Western Islands, are considered by some geographers as belonging to Africa.

South Atlantic Ocean.

St. Matthew—Ascension—St. Helena.—The three small islands of Tristan d'Acunha.

The South Indian Ocean.

Madagascar, which may be considered as the centre of an Archipelago of small islands, to which belong the Mauritius and Bourbon, the Comoro Islands in the Mozambique channel, the Sechelles, with the Amirantes; and the islands on the coast of Zanguebar.

The North Indian Ocean.

The islands of Socotra, off Cape Guardafui. The islands of the Red Sea are generally small and inconsiderable, and partake of the character of the Arabian and African coasts, to which they may be respectively assigned according to their degree of proximity.

European Possessions in Africa.

Portuguese.—The government of the Madeiras—of the Cape Verde Islands; and the small posts of Cacheu on the San Domingo, Bissao, Zinghicor, Farim and Geba—of St. Thomas, and Prince's Island—the post of Whidah in Dahomey—the captaincy or government of Congo and Angola, consisting mainly of a few towns and posts—the Mozambique government, on the coasts of Sofala and Mozambique, extending from the bay of Da Lagoa to Cape Delgado: it is divided into seven captaincies, but the real possessions of the Portuguese are now few and insecure; the chief are, the little island of Mozambique, and the settlements of Quilimané, Senna, Tette, Manica, on the Zambezi river. Melinda, once a flourishing Portuguese settlement on the Zanguebar coast, is now deserted by that nation.

English.—Bathurst, on a small isle at the outlet of the Gambia, and a few posts dependent upon it—the establishment of Sierra Leone—the establishments on the Gold and Slave Coast, all, except one, within the Ashantee territory. Cape-Coast is the chief position: the rest are of little importance—the islands of Fernando Po, occupied in 1828, Ascension, St. Helena, and the islands of Tristan d'Acunha—the colony of the Cape of Good Hope—the Mauritius, and a number of small islands belonging to the Madagascar Archipelago.

French.—The state of Algiers on the northern coast of Africa, conquered by the French in 1830—on the Senegal and Gambia coast, the district of St. Louis, and that of Goree—the isle of Bourbon, and St. Marie, near Madagascar, with a few posts on the latter island.

Spanish.—The *Presidios*, near the straits of Gibraltar in the empire of Marocco, which contain the towns of Ceuta, Melilla, &c.—the Archipelago of the Canaries, consisting of seven larger and about thirteen smaller islands.

Dutch.—The only Dutch possessions now in Africa are some posts or forts on the Gold Coast, and chiefly within the limits of the Ashantee empire: the principal place is Elmina, the residence of the governor-general.

Danish.—These are a few unimportant posts, also on the Gold and Slave Coasts, and within the Ashantee dominion. Christiansburg is the chief place, and the residence of the governor-general. Only *one* vessel went from Denmark to these settlements in 1830, and this after a lapse of several years.

American.—The colony of Liberia near Cape Mesurado, founded by the American Colonization Society. It is a private enterprise, and has for its object the settlement in Africa of free negroes from the United States. The chief places are Monrovia and Caldwell.

Ottoman.—These are really foreign possessions, being held by Turkish authorities, who are nominally dependent on the Sultan of Constantinople. They are Egypt, the eastern desert, the Wadys of Siwah, Khargeh, &c., Nubia, Sennaar, Kordofan, &c. Tripoli and Tunis can be no longer considered as at all dependent on the Sultan.

AFRICAN ASSOCIATION. A society formed in London, in the year 1788, with the design of encouraging men of enterprise to explore the interior of Africa; of acquiring by their means a knowledge of the character of the native inhabitants; and of being enabled to introduce among them the arts of civilization.

At its first formation, the Association consisted of ninety-five members, many of whom were men distinguished by their zeal in the cause of science. The management was intrusted to a committee of five persons elected from among the members. This committee administered the funds, conducted the correspondence, and appointed the persons to whom the accomplishment of its objects was confided. Sir Joseph Banks was one of the first and most efficient members of this committee.

The first person commissioned by the Association was John Ledyard, an American, who had already gone round the world with Captain Cook, and had given other proofs of his adventurous disposition. The task assigned to him was that of traversing the widest part of the continent of Africa, from east to west, in the supposed latitude of the river Niger. While preparing himself for this undertaking, and making the necessary inquiries at Cairo, where he had arrived in August, 1788, Mr. Ledyard was seized with a bilious fever and died.

The committee lost no time in supplying his place; and in October of the same year despatched Mr. Lucas, whom they selected on account of the knowledge which he had acquired in previous travels of the language and customs of the Arabs. The instructions of the committee to Mr. Lucas were, to proceed from Tripoli over the great desert of Sahara, and to return homeward by the way of the Gambia or the coast of Guinea. To fulfil these instructions Mr. Lucas proceeded from Tripoli to Mesurata, where he remained about a month collecting information, when, owing to the difficulties and dangers, caused by a state of warfare, which constantly opposed themselves to his undertaking, he was induced to retrace his steps to Tripoli, and thence returned soon after to England.

The next person engaged by the Association was Major Houghton, an officer who had acquainted himself, in the course of former journeys, with the customs of the Moors and Negroes. He arrived at the mouth of the river Gambia in November, 1790, and ascended the stream to Medina, the capital of the kingdom of Woolli, on the north side of the river. He next crossed the river Faleme, and arrived at Ferbanna, sixty-five miles S.E. of Bambouk. Endeavouring thence to penetrate the kingdom of Ludamar, Major Houghton engaged with some Moorish traders at Jarra to accompany them to Tisheet, but was treacherously plundered by them and left in the desert. After severe privation, he returned to Jarra, and there died, in September, 1791, not without strong suspicions of having been murdered.

Without being discouraged by these repeated disappointments, the Association sought for some other person to prosecute their plans, and were fortunate in meeting with Mungo Park, who sailed in May, 1795, and arrived at Jillifree, on the banks of the Gambia, and near to its mouth, in the kingdom of Barra. In December he set out from Pisania, accompanied by two negro servants and four other natives, and advanced into the kingdom of Woolli. He then went through Kajaaga, crossed the river Senegal, and proceeded through the kingdoms of Kaarta and Ludamar to Jarra. Mr. Park afterwards successfully explored the banks of the river Niger, here called the Joliba, which till then had been thought identical with the Senegal,—proceeding as far as the populous city of Sego, the capital of Bambarra, and to Silla. This last place (in lat. 14° 48′ N., long. 1° 34′ W.) was the extreme limit of his first journey, the particulars of which were communicated to the Association in 1798. The second journey of this adventurous traveller in 1804 was undertaken at the expense of Government.

In July, 1797, Mr. Hornemann, a German, left London under an engagement with the Association. This gentleman had previously endeavoured, by much study, to qualify himself for the task of exploring Africa, and with the same object remained some time at Cairo. Here, while waiting the departure of the caravan to Cassina, Mr. Hornemann was seized, together with other Europeans, but was released by order of General Buonaparte, who, on learning his destination, supplied him with passports and other facilities for his journey. He commenced his travels westward with the caravan in September, 1798, and arrived at Moorzouk, in Fezzan, in November. Here he remained for a considerable time; and in April, 1800, set out for Bornou. His last despatches were previously sent off by way of Tripoli, and expressed the confident hope of being able to penetrate farther to the southward and westward than any preceding European traveller. From that time no certain intelligence of his fate was ever heard. Vague rumours, received eight years afterwards, stated the probability of his being still alive in the interior of the country. According to one report, he was living, in June, 1803, in Cashna, where he had assumed the character of a Marabout or Mussulman saint, and was highly respected.

Mr. Nicholls was next engaged by the Association. This gentleman, who was instructed to proceed to Calabar, in the Gulf of Benin, arrived there in November, 1804, and died shortly after from the fever of the country.

A young German, named Roentzen, recommended to the Association by Professor Blumenbach, was next despatched to Africa. To fit himself completely for the journey, he acquired a competent knowledge of the Arabic language, put off his European dress, and assumed the character of a Mussulman. Great part of the year 1809 was spent by him at Magadore, that he might perfect himself in the part he was to act: he then set out, with two guides, to join the caravan proceeding to Soudan, but before he could accomplish this object, he was barbarously murdered,—a deed to which his guides were most probably incited that they might possess themselves of his property.

The last missionary of the Association was John Lewis Burckhardt, a young Swiss of good family, who visited England in 1806, and in 1808 offered his services to proceed to Africa. Between this time and March, 1809, when he sailed for Aleppo, Mr. Burckhardt remained at Cambridge studying Arabic. On his arrival at Aleppo he assumed the name of Ibrahim Ibn Abdallah, together with the eastern costume, and all the outward characteristics of a Mussulman. He remained in Syria two years and a half, which time was spent in acquiring a knowledge of all the spoken dialects of the country, and in habituating himself to the customs of the people. At the expiration of this time he set off for Nubia, crossed the Red Sea, and after visiting Mecca and Medina, arrived at Cairo in June, 1815. In the following spring he visited Mount Sinai, and returned to Cairo, where he remained until October, 1817, when he was seized with dysentery and died. The journal of his travels in Syria to the time of his arrival in Cairo was transmitted to the Association, and published. His papers of a later date, which are believed to have been highly interesting, have not hitherto reached this country, and it is feared are lost.

These repeated failures appear at length to have discouraged the Association from engaging other missionaries. A great deal of information, connected with the geography of Africa, was collected by them from various sources during the period of their active labours; and this information was communicated to the public in the occasional printed reports of their proceedings.

The Association has recently merged in the Royal Geographical Society, into which body its few remaining members were admitted in 1831. [See *Proceedings of the Association*, from 1794 to 1805; Leyden's *History of Voyages and Discoveries in Africa*, edited by H. Murray; and *Journal of the London Geog. Soc.* vol. i. p. 257.]

AFRICAN COMPANY. A regulated Company established by the act 23 Geo. II. cap. 31, (1754,) which was first charged with the maintenance of all the British forts that lie between Cape Blanco in lat. 20° 47′ N., long. 16° 58′ W. and the Cape of Good Hope, and afterwards with upholding those only which lie between Cape Rouge and the Cape of Good Hope. Previously to its incorporation, four other joint-stock companies had been successively established for prosecuting the African trade. The last of these, the Royal African Company, had an exclusive privilege by charter, under which it carried on a losing trade of conveying negroes to the plantations, and of importing gold-dust, elephants' teeth, and dyeing drugs from the inland parts of Africa. By the act which established the African Company this exclusive charter was recalled, and their forts and garrisons were vested in the regulated company. The fine which entitled any merchant to be admitted a member of this corporation was limited to forty shillings. The Company was prohibited from trading in its corporate capacity, or upon a joint stock; from borrowing money, or from laying any restraints upon the trade, which might be carried on freely from all places and by all persons, being British subjects, who should pay the fine. The government was vested in a committee of nine persons, who were elected annually by the freemen of the Company resident in London, Bristol, and Liverpool; three members being returned from each of the places, who held their sittings in London.

For the purpose of maintaining the forts and garrisons, an annual sum of about 13,000*l.* was voted by Parliament, for the due disposal of which the committee were responsible to Government. The salaries of their clerks and agents, with all other expenses of management, including compensation to the members of the committee for their trouble, were allowed out of the sums received as fines of admission from the freemen. In the course of time it happened that the whole expense of the Company came to be defrayed by the public, and for this reason the charter of its incorporation was recalled by Parliament in 1821 (1 and 2 Geo. IV. cap. 28); his Majesty being empowered to grant allowances to the officers and servants of the Company. The possessions of the Company on the west coast of Africa were by this act annexed to and made dependencies upon the colony of Sierra Leone.

AFRICAN INSTITUTION. A society established in London, in April, 1807, whose declared objects were, to collect accurate information respecting the natural productions, as well as the agricultural and commercial capabilities of the African continent, and, also, respecting the condition, intellectual, moral, and political, of its inhabitants: to cultivate friendly relations with the African people, and to promote among them the diffusion of useful knowledge:—to introduce among them the arts of civilization; to promote the pursuit of agriculture, furnishing for that purpose seeds and plants, and implements of husbandry. Another object announced by the promoters of the institution, was that of introducing useful medical discoveries among the inhabitants—an object of the highest benefit when the nature of the climate is considered. In order to accomplish these aims, the institution proposed to employ suitable agents, to establish correspondences, and to reward the exertions of individuals in promoting its purposes. It was another principal object to obtain a knowledge of the African languages most extensively used, and to reduce them to writing, with the view of facilitating the spread of information among the natives. As an important instrument for promoting these objects, the members of the institution were invited to devote their individual attention and united influence to obtain the enforcement of the law, then recently passed, for abolishing the African slave trade, and to expose all attempts to evade its provisions.

Among the early patrons of these laudable objects, were to be found many of those members of both Houses of Parliament whose exertions had procured the passing of the abolition law.

The institution disclaimed all projects of a colonising or commercial nature, and did not profess the intention of imparting religious instruction to the African people.

To provide the funds required for the prosecution of its plans, four classes of contributors were invited to associate themselves; viz., hereditary governors, whose qualification was a donation of sixty guineas and upwards; life governors, whose donations amounted to thirty guineas; governors, who subscribed annually three guineas and upwards; and members, who contributed each one guinea a-year. The affairs of the institution were to be administered by a patron, president, twenty vice-presidents, and thirty directors; the latter body being chosen annually from among the governors.

Plans so extended required, for their accomplishment, the possession of very ample funds, if, indeed, success could be reasonably hoped from any efforts, however powerfully supported, where the directing body was so far removed from the sphere of action, and must necessarily intrust the execution of its schemes to agents whose views and interests might not coincide with those of the London directors. The subscriptions obtained at the first establishment of the institution were considerable both in number and amount, but they very soon fell short of the sum required, so that in 1815 its permanent income was already considerably below 500*l.*

In the first year of its establishment, the institution sent out to Sierra Leone three African youths, who had been instructed on the plans of Dr. Bell and Joseph Lancaster; it gave directions for engaging persons qualified to teach the Arabic and Sowsoo languages; conveyed various seeds and plants to different parts of the coast, and distributed them among the natives, together with proper instructions for their culture and management; it provided machines for cleaning cotton, and a press for expressing the oil of the castor-nut; and it offered premiums to the importers of cotton, rice, indigo, and coffee of African production. With all this, its vigilance was unceasing to detect infractions of the abolition law, and the exertions of the directors were successfully applied towards the obtaining of an act of parliament declaring the slave trade a felonious crime.

If the success of the institution as regards its benevolent views of enlightening the natives has not hitherto been rendered very apparent, we must not thence conclude that its exertions have been altogether abortive. Men in a state of savage nature have never all at once become convinced of the benefits of the arts of civilization; and it appears inevitable, that in every effort to that end, much exertion must be employed fruitlessly, or to the production of a seemingly inadequate good. However small that portion of immediate good may be, we may yet hope that in the present case its ultimate effects will be such as not to disappoint the sober and rational hopes of the philanthropist.

AFRICA'NUS, LEO. [See Leo Africanus.]

AFRICA'NUS, SEXTUS JULIUS, a Christian writer of the third century, is considered by some authors to have been a native of Africa, and was, according to Cave, bishop of Emmaus, A.D. 232. Clavier, in the *Biographie Universelle*, makes him the descendant of an African family, and born in Palestine. Between the years 218 and 222, A. D., Africanus was employed in an embassy to the Emperor Heliogabalus for the restoration of Emmaus, which city, in consequence of his entreaties, was rebuilt under the name of Nicopolis. He attended the lectures of the bishop Heraclius at Alexandria, some time before the year 231.

Eusebius ascribes to Africanus a work which contains, under the title *Kesti*, a collection of passages from various authors, chiefly on physical, mathematical, and other topics which belong to domestic economy, medicine, botany, mineralogy, and the military sciences. Fragments of this work are printed among the *Mathematici Veteres*, Paris, 1693, folio, and reprinted in the 7th volume of the works of Meursius, Florence, 1746, but it is not quite certain whether this work contains the real *Kesti* of Africanus. It has been translated by Guischardt, in his *Mémoires Militaires des Grecs et des Romains*, 1758, in 4to. There exists, also, a translation by Africanus of the book of Abdias of Babylon, under the title *Historia Certaminis Apostolici*, 1566, 8vo.

The word Kestos signifies in the Greek language a girdle of various colours. Probably the title Kesti alludes to the different hues of an embroidered girdle, or to the magical power of the girdle of Venus. The *Kesti* teach, among other things, how to grow fruit in the shape of animals, or of the human countenance, and how to produce pomegranates without kernels, and figs of various colours, &c.

Valesius, Scaliger, and others, considered the contents of the Kesti to be unworthy of the Christian chronologer, Africanus, and attribute them to a pagan philosopher called Sextus; and Jerome omits the *Kesti* in his list of the works of Africanus. But Eusebius, *Hist. Eccl.* vi. 31. ed. Vales. p. 295, Suidas, Vossius, Wetstein, and others, ascribe the *Kesti* to Africanus. Compare Hamberger's *Zuverlaessige Nachrichten*, tom. ii. p. 525.

Africanus wrote a chronological work in five sections under the title of *Pentabiblos*, containing, as some learned men think, an abridgment and a continuation of Manetho's work. The *Pentabiblos* contained a sort of universal history, composed to prove the antiquity of true religion and the novelty of paganism. Fragments of this chronology are extant in the works of Eusebius, Syncellus, Malala, Theophanes, Cedrenus, and in the *Chronicon Paschale*. The *Pentabiblos* commences with the Creation, 5499 B.C. and closes with 221 A.D. The chronology of Africanus places the birth of Christ three years before the commencement of our æra. But under the reign of Diocletian, ten years were taken from the number which had elapsed, and thus the computation of the churches of Alexandria and Antioch were reconciled. [See Æra.]

According to Fabricius, *Bibl. Gr. ed. nova*, viii. p. 9, there exists at Paris a MS. containing an abstract of the *Pentabiblos*. Scaliger has borrowed, in his edition of *Eusebius*, the chronology of Africanus extant in *Geo. Syncelli, Chronographia ab Adamo ad Dioclesianum, à Jac. Goar, Gr. et Lat.* Paris, 1652, fol.

Africanus wrote a learned letter to Origen, in which he disputes the authenticity of the apocryphal history of Susannah. This letter has been printed at Basle, in Greek and Latin, 1674, 4to.

A great part of another letter of Africanus to Aristides, reconciling the disagreement between the genealogies of Christ in Matthew and Luke, is extant in Eusebius's *Ecclesiastical History*. In order to reconcile the difference between the genealogies, he has recourse to the law of adoption among the Jews, by which brothers were obliged to marry the wives of their brothers who died without children.

The fact of a man so learned and intelligent as the chronologer Africanus being a Christian, refutes the error of those who think that all Christians in the first centuries of our æra were illiterate. The criticisms of Africanus upon the apocryphal books seem to attest that he did not receive the canonical writings of the New Testament without previous examination; and from his manner of reconciling the different genealogies of Christ, it appears certain that he recognised the authenticity of the Gospels in which they occur.

AFTER-MATH is the grass which grows after the hay has been made; it is also called latter-math, rowen, or rowett, and when left long on the ground it is called *fogg* in some places. Where the land is rich and hay valuable, the aftermath is often mown and made into hay. This hay is inferior in value and nourishment to the first crop, which contains the flower-stalks of the grass. It is not good for horses, especially those which are driven fast and work hard; it is thought injurious to their wind. Cows and sheep are fond of it, and with them it is not liable to the same objection. Whether it be more profitable to cut a second crop of hay, or to feed off the aftermath, must depend on circumstances and situations. Unless the meadows can be irrigated, or well manured, taking off two crops of hay in one year exhausts them, and is apt to produce moss, which the tread of sheep and cattle prevents.

There is a practice with some farmers to leave the aftermath on the ground from hay-making time to the next spring; this is then called *fogg;* and the young grass, springing up through the old, makes it palatable to young cattle. Arthur Young mentions this practice with some commendation, as a resource in spring; but it does not accord with a well-regulated system of husbandry, in which all food should, if possible, be given in its most perfect state. The fogg, half rotten by a wet winter, cannot be wholesome food; besides, slugs and various insects breed in it. The aftermath should be fed off clean before winter. A good farmer should have hay, straw, and roots sufficient for his stock. Swedish turnips, mangel wurzel, carrots, &c., can be stored in winter and strewed upon the pastures in spring, by which the stock will be better fed, and the land improved.

AGA, the name of a dignity, and also an epithet of respect, among the Turks. It signifies literally a great man, a lord, or a commander. Some etymologists assert, that the original meaning of the word is a baton, taken as the ensign of command. In Turkey, the Aga of the janissaries, while that corps subsisted, was their commanding officer or colonel, whose place was one of high authority and dignity in the state. There is also the spahilar-aga, that is, the colonel of the spahis, or cavalry. Aga is likewise the common epithet of civility used in addressing or speaking of the eunuchs employed in the seraglio; and their chief is distinguished by the title of Capi Aga. The Capi Aga, or Capi Agassi, as he is often called, is one of the principal officers of the court of Constantinople.

AGAME'MNON, King of Mycenæ, and commander-in-chief of the Grecian army at the siege of Troy. According to the fabulous genealogies of the poets, he was fourth in descent from Jupiter, and grandson to Pelops, who came from Asia into Greece, and laid the foundation of a new dynasty of princes, which soon supplanted the older race of the Danai. Pelops acquired the kingdom of Pisa by marriage. Atreus, son of Pelops, being banished from his father's house for having slain his brother Chrysippus, fled to Mycenæ, where his sister's son, Eurystheus, grandson of Perseus, then reigned. He ingratiated himself so much with the people, that he was chosen king on the death of Eurystheus, and left the sceptre to his eldest son, (or, some have said, grandson,) Agamemnon. The dominion of Mycenæ comprehended the northern part of Argolis, Corinth, and Sicyon, with the territories annexed to them, and

Ægialos, afterwards called Achaia; thus including the whole northern coast of Peloponnesus. Menelaus, second son of Atreus, obtained the kingdom of Lacedæmon by marriage with Helena, daughter of Tyndareus and Leda. The southern and larger portion of Argolis, though governed by a monarch of its own, was probably dependent to a great degree on its more powerful neighbour of Mycenæ. It does not appear who inherited the kingdom of Pisa after Pelops: none of the four chiefs who led the Eleians to Troy were of his family, so that the degree of influence which the Pelopid princes possessed over Elis can hardly be ascertained. A large portion of Messenia, according to Strabo, was occupied by colonists who followed Pelops from Asia. Thus, in at least four, probably in five, of the six principal divisions of Peloponnesus, (Arcadia being the one excepted,) the house of Atreus had a direct family interest and influence. The exact nature of the influence is not easily defined: but the best authorities concur in bearing testimony to its existence. Homer mentions the sceptre of Agamemnon as the emblem of authority 'over all Argos (Peloponnesus) and many islands:' and Thucydides expresses his belief that the above-named monarch 'assembled the Grecian forces, not so much through favour, as fear.'

In the earliest and most credible authors, Homer and Hesiod, we find no trace of the long train of horrors which laid waste the house of Pelops, according to later writers, and especially the tragedians. At present we shall confine ourselves to relating what bears some mark of historical truth. The history of Agamemnon, before the Trojan war, is comprised in two sentences: he was the son of Atreus, whence he and his brother were called Atridæ, according to the Grecian custom of giving to the son a *patronymic* name, or a name formed according to certain rules from the *name of the father*; and he married Clytemnestra, sister of Helen. The Trojan war arose out of the abduction of Helen by Paris, otherwise called Alexander, son of Priam, King of Troy. It is commonly said, that a number of the princes of Greece having been drawn together as suitors by the extraordinary beauty of Helen, Tyndareus exacted an oath from them, that on whomsoever the choice should fall, if the maid should be carried off, all the rest should unite to recover her: and that in virtue of this oath, the confederate princes assembled under the command of Agamemnon. In reference to this story, Thucydides has expressed his belief, 'that Agamemnon got together that fleet, not so much for that he had with him the suitors of Helena, bound thereto by oath to Tyndareus, as for this, that he exceeded the rest in power.' In continuation, the historian lays great stress upon his naval power, as evinced by his being, in Homer's words, 'king of many islands,' and by his lending sixty ships to the Arcadians, besides conducting a hundred filled with his own followers, a larger number than was led by any other chief.

The assembled fleet was detained at Aulis by contrary winds. The seer Calchas, being consulted how the anger of the gods might be averted, and the delay obviated, declared that Iphigenia, daughter of Agamemnon, who had incurred the displeasure of Diana by killing her favourite stag, must be sacrificed to the goddess. The natural reluctance of the father was overcome by importunity and ambition; and the intended victim was summoned to Aulis, under pretence of betrothing her to Achilles. At the point of death she was miraculously saved by Diana, whose priestess she afterwards became among a savage people of Asia, called the Tauri. This story is related neither by Homer nor Hesiod: it rests, however, on the early authority of Pindar, Pyth. ii., and Æschylus; and is pregnant with too important consequences to be omitted, since the alienation of Clytemnestra from her husband is said by those authors to have originated in her horror of this unnatural action. The siege of Troy was protracted for ten years. The most memorable event of it is the quarrel between Agamemnon and Achilles, the subject of the Iliad; in which the former placed himself very completely in the wrong. Homer represents him as brave, and expert in arms, insomuch that when a Grecian warrior was selected by lot who should contend with Hector in single combat, it was the general prayer that the lot might fall on Ajax, Diomedes, or Agamemnon. Still it is as the commander, rather than as the soldier, that he is presented to our notice, and usually with some reference to his wealth and power; 'king of men' is the distinguishing epithet constantly added to his name, as 'swift footed' is to the name of Achilles. Hesiod also (Fragm. 48) says that the Olympian god has given strength to the descendants of Æacus, wealth to those of Atreus. Returning from Troy he was treacherously murdered by his wife; who, during his absence, had formed an adulterous attachment to Ægisthus, son of his uncle Thyestes. This catastrophe is the subject of the Agamemnon of Æschylus, one of the most sublime compositions in the range of the Grecian drama. Orestes, son of Agamemnon, then a child, was saved by the care of his tutor, and timely flight. After passing seven years in exile, he returned in secret, avenged his father's death by the slaughter of his mother and of Ægisthus, and recovered his paternal kingdom, which he ruled with honour.

These legends of the house of Agamemnon formed a favourite subject with the Greek tragedians. Three of the seven remaining plays of Æschylus are founded on it, the *Agamemnon*, the *Chophorëi*, which has for its subject the revenge of Orestes, and the *Eumenides*, which relates the remorse and madness of Orestes, and his trial and acquittal before the Athenian court of Areiopagus. The Electra of Sophocles has the same subject as the Chophorëi. Euripides has two tragedies on the story of Iphigenia; and one called the Electra, which has the same subject as the Chophorëi and Electra of Sophocles, but is much inferior to both of them. The Orestes of the same author relates the history of Orestes subsequent to the death of Clytemnestra.

A'GAMA, in zoology, a genus of reptiles belonging to the order of saurians, and family iguanians, as established by Baron Cuvier in the *Règne Animal.* The division to which this genus appertains is one of the four natural orders into which M. Brogniart distributed the whole class of reptiles or amphibia of Linnæus, and in which he has been followed by the most judicious subsequent zoologists. The earlier division by which Linnæus proposed to arrange the amphibia in two orders, reptiles and serpents, or those with and those without feet, though plausible in appearance, and, to a certain extent, readily applicable to practical purposes, is, in reality, but little conformable to the physical nature and zoological conformation of these animals; because its principles do not comprehend all the characters which direct and influence their habits and economy. M. Brogniart, in joining to the Linnæan principle of division taken from the organs of locomotion, the additional consideration of the comparative quantities of respiration in this class, has laid the foundation of a distribution more agreeable to the system of nature, and, as far as it goes, perhaps, more satisfactory, than the primary divisions in any other class of animals. The four orders thus established by M. Brogniart, and now generally admitted by naturalists, are, 1st. the *Chelonians,* (or tortoises and turtles,) which have two auricles in the heart, four legs, and the body defended by two large plates or bucklers, the upper formed by the union and dilatation of the ribs, and the lower by the sternum: 2d. the *Saurians,* (or lizards,) with two auricles in the heart, four, or, in a few instances only, two legs, and bodies covered with scales; 3d. the *Ophidians,* (or serpents,) with two auricles in the heart, no feet, and bodies generally covered with scales: and 4th. the *Batrachians,* (or frogs, toads, salamanders, &c.,) which have only one auricle in the heart, four, or rarely two legs, and naked bodies; and which, moreover, like the insect tribes, are subject to a metamorphosis, passing, with age, from the state of a fish which respires through gills, to that of a quadruped breathing air by means of lungs. The example of this last order presented by the tadpole or young frog, and of the transformation which it undergoes upon assuming its perfect reptile form, are familiar to every one.

Having given this general preliminary view of the principles of classification established in this class of animals, in order that the reader may be enabled to comprehend the precise import of the terms which we are obliged to employ, it is only necessary to observe farther, that Baron Cuvier has subdivided the order, saurians, into six natural families, distinguished from one another by peculiar and influential characters. Of these the iguanians are the third in order; they differ from the other families chiefly in the nature of the tongue, which is thick, fleshy, and attached to the under-jaw; consequently, without the power of being protruded, as in the generality of reptiles. The tongues of the crocodiles and alligators, indeed, are of the same form; but from these destructive reptiles the iguanians are zoologically distinguished by their long flexible toes not united by membranes, and generally by their diminutive size, round tails, and small imbricated scales. M. Cuvier again subdivides the family iguanians into two smaller sections, or sub-families; the iguanians, properly so called, which, besides the ordinary series of maxillary or jaw-teeth, have likewise two small additional rows on the posterior margin of the palate; and the agamians, which want these additional or palatic teeth. To the latter sub-family, of which, indeed, it is the type, belongs the genus agama, the subject of the present article, and of which we proceed to describe the characters, and a few of the principal species.

In the form of their heads and teeth the agamas resemble the common lizards, but differ in the imbricated scales which cover their tails. These animals have the body thick and shorter in proportion than the generality of the saurian family; the skin is lax and capable of being distended or puffed out with air at the will of the reptile: the whole body, as well as the head, neck, and feet, is covered with minute rhomboidal or hexagonal scales, often prolonged in the form of little spines, and bristling when the body is inflated with air. The head is short, broad, and flat, particularly towards the occiput; the neck also is short, and the tail seldom longer than the body. These proportions give the agamas much of the hideous and disgusting appearance of toads, and, indeed, Seba and other authors have occasionally confounded them with these reptiles. In many parts of South America they are called chameleons, from their power of dilating the skin with air, and thus, to a certain extent, imitating these animals in the various hues which they are capable of assuming. In other respects the various species of agamas differ so considerably from one another, as to have induced Baron Cuvier to arrange them in separate subgenera, distinguished by the form of their scales and the presence or absence of pores in the thighs. Spix, and some other writers, are inclined to regard these distinctions as real generic characters, but they are obviously of too little importance, and exercise an influence too confined over the habits and economy of the animals, to warrant us in adopting the ideas of these zoologists. We shall therefore follow the more judicious sentiments of M. Cuvier, in regarding these subdivisions as of no intrinsic value in themselves, but merely useful, as a practical means of distinguishing the species. It will be sufficient at present to indicate these different subgenera, and to refer to the works of the above-mentioned naturalists for a more particular account of their several and respective characters. Generally speaking, the agamas have no thigh pores; some, however, are provided, as is the case with many other saurian reptiles, with a row of these pores along the inner surface of each thigh; some species have the toes so short and rigid as to compel them to live entirely on the surface of the earth, where they reside among rocks and heaps of stones, and conceal themselves in the crevices; others again, which have long and flexible toes, ascend trees with great facility, and sport among their branches with the utmost security. All are of a diminutive size, and, like most other reptiles, feed upon insects and other small animals: one or two species, nevertheless, are reported to be herbivorous. Their geographical distribution is very extensive, and embraces all the hot and temperate parts of the known world: Asia, Africa, Australia, and South America have each their appropriate species, which often differ from one another so slightly, that much confusion still prevails among their characters and synonyma. The most remarkable species are, of those without pores on the interior face of the thighs,—

The muricated agama (*Ag. Muricata, Cuv.*), first described by the celebrated John Hunter in the zoological part of White's *Voyage to New South Wales*. It is one of the most common lizards of that colony; measures upwards of a foot in length, comprehending the tail, which is twice as long as the body, and, from the great length and perfect division of its toes, readily ascends trees, and lives entirely in the woods, where it hunts about for insects and caterpillars. Its general colour is a brownish grey, marked with dusky bars, which run in a longitudinal direction on the body, but transversely on the legs and tail. The scales which cover the upper and outer parts of the trunk and extremities are rhomboidal, and carinated, or elevated into sharp-pointed ridges, forming parallel lines or rows of spines upon the back and sides, from the shoulders to the very point of the tail. The head is covered with similar scales, all directed backwards and prolonged upon the occiput into a crest of weak spines. The toes of all the feet are well separated, and furnished underneath with small pointed scales; the two middle toes of the hind feet are nearly twice the length of the others.

[Agama muricata.]

The Agama Barbata of Cuvier is another species from the same locality. It is rather larger than the muricated agama, but preserves the same relative dimensions, and lives in the forests in the same manner. A range of large spinous scales passes in transverse bands over its back and tail, and the throat is covered with long-pointed scales, forming a sort of beard, though neither so strong nor so conspicuous as in the guanas. Similar scales cover the sides and form two oblique crests behind the ears; the belly is spotted with yellcw, and the throat is capable of being distended at the will of the animal. This species is likewise figured and described in White's *Voyage*, p. 255, but was considered by Mr. Hunter as a mere variety of the former.

Other species of this division, having pores on the inner surface of the thighs, are the *Leiolepis* (A. Guttata) of M. Cuvier, of Cochin China, with white rays and spots on a bright blue ground; the *Tropidolepis* (A. Undulata), of a uniform dark blue colour with a white cross on the throat, and which, as well as the kindred species, *A. Nigri-Collaris* and *A. Cyclurus*, described by Spix, inhabits various parts of South America; the *Brachylophes* (A. Vittata), which seems to form the connecting link between this genus and the

[Agama aculeata.]

guanas, from which latter it is distinguished only by the absence of teeth in the palate; it is found in India, and has light blue bands upon a dark blue ground: and, lastly, the *Physignathes* (A. Cocincinus), from the Malayan peninsula, remarkable for its large size, uniform blue colour, but more particularly from being one of the very few species of saurian reptiles which feed upon vegetable substances; Baron Cuvier assures us that it lives entirely upon fruits and nuts. Of the agamas without pores in the thighs, the principal species are, the *Spinous Agama* (A. Aculeata) of a yellowish grey colour with numerous transverse brown bands. All the upper parts of the body are covered with elevated scales, forming small pointed pyramids of four sides; the body is short and thick, the tail likewise short, the head broad and flat, and the belly protuberant. Excepting in the length of the tail and the body being covered with scales, the whole animal has much of the form and appearance of a frog or toad: it is found at the Cape of Good Hope, and is of larger size than the generality of the other species.

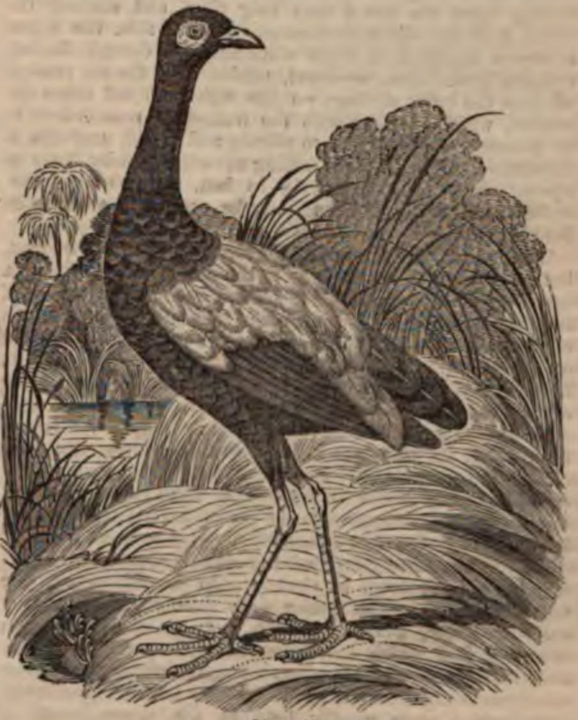
The *Tapayaxin* (A. Orbicularis), of Mexico, is very similar to the species last described in its form and proportions, but is still shorter and thicker. The extraordinary figure of this reptile, approaching almost to the form of a perfect sphere, its broad flat head, its skin covered with small tubercles or warts interspersed among the scales, and the faculty which it possesses of distending its body with air, and to a certain degree assuming different shades of colour, have caused it to be sometimes compared to a toad, and sometimes to a chameleon; but the truth is, that it has no actual relation or affinity to either of these animals, but is indebted solely to its naturally disgusting aspect, for the calumnies which the early Spanish writers have heaped upon it. The scales of this species are small, pointed and rough on the upper parts, smooth and flat beneath; on various parts of the back they are elevated into insulated spines, ranged in six or eight longitudinal rows, but without much regularity: the ground colour is dark grey above, with irregular brown blotches, and beneath yellowish red, speckled with small black spots. The legs are short and thick and the toes of equal length, both before and behind. The tapayaxin inhabits the mountainous and rocky parts of South America, from the Isthmus of Darien to Patagonia; according to Ray, it is capable of domestication, and even recognises and shows a kind of attachment to those who feed it.

Other subgenera and species belonging to this division of the agamas are *Trapelus* (A. Ægypticus), remarkable for its change of colour, even more sudden than that of the true chameleon; the *A. Calotes*, of a bright blue colour with transverse white marks on the sides, from the Mollucca Islands; the *Lophyres* (A. Gigantea, Kuhl), with a crest of long elevated spines on the neck; and the *Lyriocephalus* (A. Scutata), which has a similar elevated crest along the back, and the tail keel-shaped. This latter species, in many respects a most singular reptile, inhabits Bengal, and lives upon fruits.

In the short account which we have here given of this extensive genus, we have confined our remarks principally to the general characters and most remarkable habits of these animals, as far as the latter have been observed; but it is to be regretted that we possess fewer authentic observations upon the manners and economy of reptiles, than of almost any other class of animals. Of the many thousand different species of reptiles enumerated in the most complete catalogues of zoologists, it may be safely affirmed, that we do not know the habits of as many dozens; yet this defect of information is to be attributed only to the inattention or ignorance of travellers, for these animals afford at least the same facilities for observation and experiment as mammals and birds, and much greater than fishes or insects. For ample details concerning the specific differences of the agamas, we refer the reader to the works of Cuvier, Dandin and Merrem.

A'GAMÆ, in botany, is a name given by some authors to the large division of the vegetable kingdom, called Flowerless, and may be considered equivalent to the older term, Cryptogamic plants. The word, which means sexless, has been proposed upon the hypothesis that the whole of the flowerless class is absolutely destitute of stamens and pistilla. Although few persons can now be found who entertain any doubts as to such a fact, yet the invention of a new term in consequence, has been generally considered superfluous. It may be perfectly true, that ferns, and mosses, and lichens, and confervæ, and fungi, are wholly destitute of sexual organs, and yet the term agamæ may be unnecessary: for this reason it is seldom employed.

A'GAMI (*Trophia crepitans*, Latham), an interesting bird, sometimes also termed the gold-breasted trumpeter, classed by Pallas among cranes, by Brisson among pheasants, and making the first genus in Temminck's *Alectorides*. It is the size of a pheasant or large fowl, being twenty-two inches in length, but appears larger from having a long neck, and from standing high on its legs. It bears some slight resemblance to the pheasant in the glossy iridescent green on the breast, and in a space round the eyes naked of feathers; but has a very short tail, consisting of twelve black feathers, over which the long, loose, silky scapulary rump plumes hang droopingly. Its long greenish legs assimilate it to wading birds (*Grallatores*), but it is said not to have the habits of these, never visiting fens and the margins of water, and living wholly in upland forests and arid mountains. It inhabits the forests of tropical America, and never visits the cleared grounds or the settlements. According to M. Monoucour, it is very gregarious, being found in numerous flocks, which walk and run, but rarely fly, and, when they do, seldom rise more than a few feet above the surface of the ground. Even when pursued they trust most to their speed in running.



[Agami.]

Several naturalists have given accounts of the Agami in a domestic state. Its docility and attachment to man are remarkable. 'The Agami,' says Monoucour, 'is not only tamed easily, but becomes attached to its benefactor with all the fondness and fidelity of the dog; and of this disposition it shows the most unequivocal proofs. When bred up in the house, it loads its master with caresses, and follows his motions; and if it conceives a dislike to persons on account of their forbidding figure, their offensive smell, or of injuries received, it will pursue them sometimes to a considerable distance, biting their legs, and testifying every mark of displeasure. It obeys the voice of its master, and even answers to the call of all those to whom it bears no grudge. It is fond of caresses, and offers its head and neck to be stroked; and, if once accustomed to these familiarities, it becomes troublesome, and will not be satisfied without continual fondling. It makes its appearance as often as its master sits down to table, and begins with driving out the dogs and cats, and taking possession of the room; for it is so obstinate and bold, that it never yields, and often, after a tough battle, can put a middle-sized dog to flight. It avoids the bites of its antagonist, by rising in the air, and retaliates with violent blows with its bill and nails, aimed chiefly at the eyes; and after it gains the superiority, it pursues the victory with the utmost rancour, and, if not parted, will destroy the fugitive. By its intercourse with man, its instinct became moulded like that of the dog; and we are assured that it can be trained to tend a flock of sheep. It even shows a degree of jealousy of its rivals; for, when at table, it bites fiercely the naked legs of the negroes, and other domestics, who come near its master.'

The peculiar noise which these birds make, without opening the bill, is one of their most remarkable characteristics. This noise is no doubt produced by a peculiar conformation of the organ of sound. According to Pallas, the *larynx*, which is on the outside of the breast, is about as thick as a swan's quill and almost bony, becomes much more slender, loose, and cartilaginous when it enters within the breast, where two semicylindrical canals of a membranous texture, and capable of being extended, proceed from it. The air-bag on the right side descends to the pelvis, and within the breast it is divided into three or four cells by transverse membranes. The air-bag on the left side is narrower. Vosmaër tells us that the sound is sometimes preceded by a wild cry, interrupted by a call somewhat like 'scherck, scherck,' and then follows the characteristic noise somewhat resembling the cooing of pigeons. It utters, in this way, five, six, or seven times, with precipitation, a hollow noise nearly resembling the syllables 'too, too, too, too, too, too,' resting upon the last a very long time, and sinking the sound gradually till it terminates. During this, the breast is seen to heave, as in birds, while singing, though the bill remains shut. It is, no doubt, produced by the air pressed up from the lower air-bags on the right and left above described, which meeting with the transverse membranes in its passage, causes them to vibrate and sound, and this is communicated to the surrounding muscles, and by these to the external air; so that it is, in fact, a sort of ventriloquism, and requires not the bill to be opened in order to be heard.

The Agami, like the rest of the alectorides, builds no nest, but scratches a shallow place at the root of a tree where it deposits its eggs, from ten to sixteen in number, and of a light green colour. They are somewhat larger than a hen's egg, and of a rounder form. The down remains a long time on the young, and grows into long silky plumes very close, like fur, and it is not till they are one-fourth the size of the adult birds, that the true feathers appear.

Dr. Latham tells us, that 'one of these Agamis, a young bird, found its way into a farm-yard in Surrey, and associated with the poultry. It was perfectly tame, and, on one occasion, accompanied the hounds for three miles, and kept up with them. It was last in the possession of Lord Stanley, but died on its way into Lancashire.'

A'GAPÆ, the plural of the Greek ἀγάπη, (*agape*,) which signifies love, or charity. In the history of the Christian church, the agapæ were those meetings of the early believers, where they sat and ate, at a common table, of food which had been provided by the voluntary contributions of the members of the society, the entertainment being concluded with the holy kiss. These meetings, which were usually held in the same house or apartment in which they assembled for divine worship, are at least mentioned once in the *New Testament*, namely, in the 12th verse of the epistle of Jude, where it is said of certain unworthy brethren, 'these are spots in your feasts of charity:' the Greek word here is *agape*. It is probable also that St. Paul alludes to the same thing in 1 *Cor*. xi. 20, where his language would seem to imply that the agapæ had been originally instituted chiefly for the purpose of celebrating the sacrament of the Lord's Supper. But whether they arose in this way, or from those feelings of brotherhood and that charity towards their poorer brethren which were so strongly inculcated upon the first followers of Christianity, both by the religion they professed and the circumstances amidst which they were placed, it is certain that even in the days of the apostles these meetings had been occasionally perverted from the purpose of their institution. St. Paul, in the passage to which we have just referred, charges the Corinthians that, when they came together into one place, 'in eating every one taketh before other his own supper; and one is hungry and another is drunken.' And he continues, 'What? have ye not houses to eat and to drink in?' concluding, after an explanation of the solemn and spiritual manner in which the holy supper ought to be partaken of, with the general direction, 'Wherefore, my brethren, when ye come together to eat, tarry one for another. And if any man hunger, let him eat at home.' These love-feasts also gave great occasion of scandal to the enemies of the faith. The reader may find an account of the accusations of which they were made the groundwork by some of the pagan writers in the sixteenth chapter of Gibbon's History. They seem, however, to have continued to be generally celebrated for several centuries. Ecclesiastical writers mention three kinds of them,—first, those which took place at marriages, called the nuptial or connubial agapæ, to which the bishop or pastor was usually invited: second, the anniversary, or, as they were called, natal agapæ, which were held in the churches on the festivals of the martyrs: and, third, the funeral agapæ, at the interments of members of the congregation. The celebration of the love-feasts in the churches was at length expressly forbidden by the 25th canon of the council of Laodicea, in A.D. 364; although the enactment would seem for a considerable time not to have been quite effectual, since we find it repeatedly renewed by subsequent councils. Nor does the practice under improved regulations appear to have been discontinued in all circumstances by the heads of the church. In the sixth century, as we are informed by Bede, Pope Gregory, in his instructions to Austin when he sent him to Britain to convert the Saxons, advised him to allow the new converts to feast together on saints' days, and the anniversaries of the dedication of the churches, not in the churches themselves, but in sheds fashioned with green boughs close by them, to the glory, he says, of God, as they had formerly done to the honour of the devil. A great deal of ingenious speculation has been expended in the attempt to discover traces of the Christian agapæ, both among the Jews and pagans before the institution of our religion, and in the latter times of the church. But the only thing exactly corresponding to the primitive love-feast is the practice which has been introduced under the same name by certain modern sects, especially the Moravians and the Sandemanians.

AGAPHITE. [See TURQUOISE.]

AGARI'CIA, (Lamouroux.) The mushroom madrepore, a genus of coral madrepores, so called from its resemblance in form to mushrooms (*Agarici*). The animal inhabitants of agaricia are unknown, with the exception of a single species observed by M. Lesueur on the shore of St. Thomas in the Antilles. Lamarck enumarates five, and Parkinson seven species.

AGA'RICUS is the generic name by which all the species of mushrooms properly so called are collectively known. It comprehends such plants of the fungus tribe, as have a cap (or pileus) of a fleshy nature, supported upon a distinct stalk, and a number of parallel unequal vertical plates or gills arising out of the cap, and inclosing the particles by which the species are reproduced; particles which the vulgar call seeds, and the learned sporules. This genus consists, according to the latest writers, of not fewer than a thousand species, inhabiting meadows, and heaths, and rocks, and masses of decaying vegetable matter, in all Europe, and in many other parts of the temperate regions of the earth. Among them, a large proportion are poisonous, a few are wholesome, but by far the greater are altogether unknown in regard to their action upon the human constitution. The species are often extremely similar; there is no means of distinguishing botanically the tribes that are poisonous from such as are wholesome, but in every case practice is requisite to determine that point independently of general structure. It is for this reason that the use of wild mushrooms is so dangerous, and that a French botanist, of no little celebrity, would never suffer any to be brought to his table that had not been raised by art in a garden. Indeed there is this most remarkable fact connected with their qualities; a fact which seems to show that their properties depend upon climate and situation, and accidental circumstances, rather than upon any specific peculiarities; those kinds which are wholesome in one country are not so in another; thus, in Great Britain, the common mushroom (*Agaricus campestris, fig.* 1.), the fairy ring agaric (*A. pratensis, fig.* 2.), and the *A. Georgii*, are the only sorts that it is quite safe to eat; while the Fly agaric (*A. muscarius, fig.* 3.) and *A. virosus* (*fig.* 4.) are extremely poisonous. But in other countries of Europe it is different. In France, in Italy, and especially in Russia, a usual aliment is afforded by a great variety of species which, although very common in this country, it would be extremely dangerous to eat; and, on the other hand, even the dangerous A. muscarius is a species of food in Kamtschatka.

We propose to point out in this article what the distinctions are, by which it has been supposed that the eatable and poisonous species may be recognized, because the reader of such a work as this would be more likely to be misled by imperfect descriptions than benefited by speculative distinctions. We shall therefore confine ourselves to a few easy, plain, and intelligible observations, which it is to be hoped cannot possibly lead to error.

Of the thousand species thus much is certain, that all having the following characters are poisonous:—

1. Such as have a cap very thin in proportion to the gills.
2. Such as have the stalk growing from one side of the cap.
3. Those in which the gills are all of equal length.
4. Such as have a milky juice.
5. Such as deliquesce; that is, run speedily into a dark watery liquid.
6. And lastly, every one that has the collar that surrounds the stalk filamentous, or resembling a spider's web.

As to the rest, the *only eatable* kinds that can be safely employed in Great Britain are the following:—

A. campestris, the common mushroom, (fig. 1,) the species that is so commonly raised artificially for food. This is readily known in any state by its fragrant odour, by which alone it may be always recognized, and the absence of which is extremely suspicious. When in a very young state, it resembles little snow-white balls, which are called *buttons;* afterwards it acquires a stalk, separates its cap, and becomes shortly conical, with liver-coloured gills, and a white thick fleshy cap, marked with a few particles of grey. At a more advanced age the cap is concave, the colour grey, and the gills black; in this state it is called a *flap*. For the method of cultivating it, and for its physiological characters, see MUSHROOM.

A. Georgii is like the latter, but its gills are always very pale, and its flavour inferior. It is said occasionally to weigh as much as fourteen pounds.

A. pratensis, or *oreades*, the fairy-ring mushroom, is so well known by its popular designation as to require no description. Well may it have gained that name; for, in former times, there would, doubtless, be great difficulty in imagining how such productions could spring up in a few hours in the regular rings they appear in, without the aid of some supernatural agency. The use to which this species is usually applied is that of being powdered and mixed with rich sauces, after having been previously strung upon a line, and dried in the shade.

[Eatable Agarici.]

[Poisonous Agarici.]

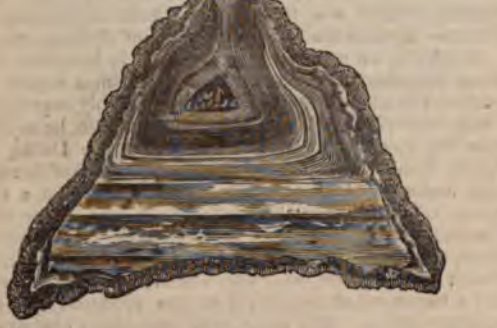
Those who have curiosity and courage to adventure on determining the qualities of others of this family may consult the works of Persoon, De Candolle, Withering, and other writers, in which they will find ample information. But before commencing their experiments, we would recommend to their attention the following circumstance.

A lieutenant in the French army ate some mushrooms supposed to be of a wholesome kind, at ten in the morning. At seven in the evening he was attacked with severe colic; at ten his wife began to experience the same sensations, attended with nausea. In the course of the night they were both attacked with violent vomiting and purging, accompanied by intense thirst. This was succeeded by severe cramps, and the pulse became hard, weak, rapid, and irregular. At ten the next morning the husband died, and the wife at six in the evening. But the person from whom the agarics had been procured, as well as all his family, had eaten abundantly of them without inconvenience. Upon a careful inquiry, it appeared that the latter had well salted, then boiled for some time, and afterwards pressed the agarics before eating them,—precautions which the unfortunate lieutenant had neglected.

AGA'SIAS, a Greek sculptor of Ephesus, whose age is not accurately known. The statue now at Rome called the Borghese Fighter, which is a fine specimen of skill in representing a figure in action, and also shows a careful study of external anatomy, is the work of this Agasias. On the support behind the figure is the following inscription in Greek.—*Agasias the son of Dositheus of Ephesus made it*

A'GATE, an ornamental stone used in jewellery, and for some purposes in the arts: it is sometimes called Scotch pebble. The name is derived from the Greek ἀχάτης (achates), a stone described by Theophrastus, and which, he says, came from the river Achates, in Sicily; now the Drillo, in the Val di Noto. It is one of the numerous modifications of form under which silica presents itself, almost in a state of purity, constituting in the agate 98 per cent. of the mineral. The siliceous particles are not so arranged as to produce the transparency of rock crystal, but a translucent, sometimes almost opaque substance, with a resinous or waxy fracture; and a variety of shades of colour are produced by a minute quantity of iron. The same stone sometimes contains parts of different degrees of translucency, and of various shades of colour; and the endless combinations of these produce the beautiful and singular internal forms, for which, together with the high polish they are capable of receiving, agates are prized as ornamental stones. Although occasionally found in other rocks, they are most usually met with in that variety of the trap rocks called Amygdaloid or Mandelstein, forming detached rounded nodules, not cemented to the base or mass of the rock, but easily separable from it, and having generally a thin layer of green earth interposed, and a rough irregular exterior, as if moulded on the asperities of the sides of a pre-existing cavity. The siliceous particles have often, but far from constantly, arranged themselves in thin layers parallel to the external surface of the nodule; sometimes the nodule is not solid, but a hollow space is left in it, studded with crystals of quartz; and not unfrequently crystals of carbonate of lime and other minerals, totally distinct in composition from that of the agate, are superimposed on those quartz crystals.

The theory of the formation of agates is a problem of great difficulty, and we must be much further advanced than we are, in our knowledge of the chemical processes of nature in the mineral kingdom, before we can expect to throw any light on this very obscure subject. The great supply of agates is from a class of rocks to which all geologists now assign an igneous origin, analogous to that of lava in existing volcanos. The theory divides itself into two parts; first, the formation of the cavities in which the agates are found; and, secondly, the filling of these cavities. With regard to the first, we have many analogies from modern lavas, and from processes of art, to guide us to a pretty satisfactory conclusion. Gases are evolved in great quantities by volcanos, and if produced at the same instant with a flow of lava, they would rise in bubbles in the melted mass; but in proportion as that became more viscid they would rise with greater difficulty to the surface, and when it consolidated would form cavities, the shape of which would be determined by the nature of the pressure of the surrounding viscid lava. To account for the filling up of the cavities three theories have been proposed: one supposes the siliceous matter to have been introduced in aqueous solution from without, and to have been gradually deposited in the cavities; another, that, in obedience to some peculiar laws of attraction, it has separated from the rest of the rock, and insinuated itself into the hollows left by the gases; and a third, that these hollows were filled by the sublimation of the silica and other materials from the rest of the mass by the action of heat. Each hypothesis is supported by particular cases, which it satisfactorily explains, but there are probably as many against as in favour of each; all of them imply conditions of chemical action different from anything of which we have had experience. We frequently find, it is true, masses of siliceous petrified wood in which hollows of the tree have been filled with agate, not to be distinguished from many nodules found in the trap rocks; and that the matter of the agate must have been introduced into the wood by aqueous infiltrations there can be no doubt. but, in this case, the whole substance of the sustaining mass, the wood, is penetrated by siliceous matter; and the difficulty of the theory of infiltration, in the case of the trap rocks, consists in the absence of any trace in the rock of the channel by which the solution of siliceous matter could have arrived at the cavity. The following section of an agate is a good example of the filling up of a cavity by infiltration, for it is evident that the siliceous matter, in whatever way it may have arrived, was introduced at the point *a*, and that there was a gradual deposition of it. Such examples would be more frequently met with, if there was anything in the external coat to tell us in what direction to slit the stone: this same specimen might have been cut in many directions without throwing any light upon its mode of formation, and the section we now see was an accidental cut in the right direction. An attentive consideration of the products of volcanos may lead to some satisfactory conclusion; for although agates have not been found in lavas, cavities in them are often partially or entirely filled with minerals distinct from any in the rest of the rock.



[Agate.]

Agates are often found as loose pebbles in the beds of rivers, or in gravel, but in those cases they have been derived from the disintegration of Amygdaloids, the base of which is very often subject to decomposition when exposed to air and moisture, and then the siliceous nodules fall out. They vary in size from that of millet seed to a foot in diameter; but one, two, and three inches in diameter are the most common.

The stones distinguished by mineralogists and lapidaries by the names of carnelian, calcedony, onyx, sardonyx, Mocha-stone, blood-stone, chrysoprase, and plasma, are so closely allied to agate, that they may be conveniently described under this head. In chemical composition they are not distinguishable, except in the case of the chrysoprase by its colouring matter.—CARNELIAN, so called because some kinds are of a flesh colour (*carnis*, Latin for flesh), is that variety of a uniform colour which is of most common occurrence: carnelians are never figured or striped. The colours are shades of red and yellow, the deep clear red being the rarest and most valuable. The great supply of carnelians is from Japan, where they exist in vast quantities, and they are also imported from Bombay, being collected in the province of Guzzerat; but the best, according to Niebuhr, come from the gulf of Cambay. Many of the antique gems are engraved in carnelian, and it is now much used for seals.—CALCEDONY, so called from having been early found at Calchedon (sometimes incorrectly written Chalcedon) in Bithynia, opposite Constantinople, is also of a uniform colour, generally of a milky-white or pale yellow, like turbid jelly, often with an internal wavy structure in the form of stalactites, and very generally with a peculiar mammillary surface. It is found in great abundance in the Faroe Islands, in Iceland, in Cornwall, and many places of Great Britain, as well as other countries; sometimes in large masses, from which cups and other vessels are formed. Pliny describes it as being found in the neighbourhood of Thebes in Egypt and as brought to Rome from Carthage.—ONYX. In this agate the siliceous particles are arranged in alternating horizontal layers of opaque white and translucent blue, grey, or brown; and because these have a resemblance to the marks on the human nail, the stone was called from the Greek word for nail, ὄνυξ (*onyx*). It was known to the ancients, and was employed by them, as it is now, for those beautiful gems called cameos, the figure being cut out of the opaque white, the dark part forming the ground, or the contrary. It is most valuable when the contrast of colours is strong, and when the layer is thick enough to give a high relief to the object to be engraved. In the royal library at Paris, there is an antique cameo cut out of an onyx with four layers, representing the apotheosis of Augustus, eleven inches by nine, which is supposed to be the finest in existence. Agates with an onyx structure are not uncommon, particularly among calcedonies, but the finest are brought from India. Cameos are sold at Rome which are made from a thick shell, having different coloured layers like an onyx.—SARDONYX is a variety of onyx which is supposed by some to have received its name from having been brought from Sardes, in Lydia. By others it has been said that the name comes from Sardo, the Greek name of Sardinia, there being some reason for thinking that the Carthaginians brought the stones from that island, and exported them during their occupation of it. In this the opaque white alternates with a rich deep orange brown of considerable translucency, and as this is of rare occurrence the sardonyx is of greater value. The finest are brought from the east, and some antique gems are formed of them.—MOCHA-STONES and MOSS AGATES are semitransparent calcedony, including various ramified forms, produced by iron, manganese, bitumen, and chlorite or green earth, but sometimes also, as has been proved by Daubenton and Mac Culloch, produced by the presence of real vegetable bodies, such as confervæ and mosses. The first are found in Guzzerat, but received their name from having been brought from Mocha, in Arabia.—BLOOD-STONE is a green agate coloured by chlorite, with numerous bright red spots like drops of blood; called also heliotrope and oriental jasper.—CHRYSOPRASE (from χρυσέος, *chruseos*, beautiful—and πράσον, *prason*, a leek) is a rare apple-green calcedony, found in Silesia, which owes its colour to the presence of the metal nickel;—and PLASMA is another scarce green semitransparent calcedony, but of a dark tint, which, in the opinion of Mac Culloch, is coloured by chlorite.

The great supply of the figured agates of commerce is from Oberstein, in the old Palatinate, about thirty miles east of Treves, and forty-five miles south of Coblenz. When they were used as buttons, knife-handles, &c., the trade was more extensive than at present. They are found in many parts of Scotland, especially at the Hill of Kinnoul, near Perth, where there is an amygdaloidal trap very full of fine specimens.

AGATHA'RCHIDES, a Greek writer on geography, a native of Cnidos, in Asia Minor. He lived in the time of Ptolemy VI., called Philometor, king of Egypt, (who reigned from B.C. 181 to 145,) and wrote numerous works on geography, and among them, one on the Erythræan Sea.

This work is now only known to us by extracts from the first and fifth books preserved by the Greek patriarch Photius, and some extracts in the compiler Diodorus. The works of Agatharchides doubtless contained a great deal of useful information, as we may fairly infer from the character of the fragments which remain. He is the earliest extant writer who attributes the annual rise of the Nile to the periodical rains in the upper regions of that river: (Diodorus, i., 41.) he has left a very minute and curious account of the mode of working the gold mines which lay between the Nile and the Red Sea; and he is the first extant writer who has mentioned the giraffe or camelopard (*Camelopardalis*), a singular quadruped peculiar to the African continent.

His remarks on the mode of hunting elephants, and on the inhabitants of the Red Sea coasts, are curious, and prove him to have been an inquisitive and careful writer.

What remains of Agatharchides may be seen in Hudson's *Minor Greek Geographers*, vol. i. The description of the gold mines is also to be found in Diodorus, iii., 12.

AGATHE'MERUS, a Greek writer who lived about the middle of the third century, and wrote a short treatise on general geography. The Greeks seem to have applied themselves for many centuries from the time of Herodotus downwards to geographical inquiry, and the nation was at no period deficient in men who laboured to give precision to the science, and to arrange all the known facts in systematic treatises. What we are now labouring to do at the present day, Agathemerus attempted for his age; though his work, as we now possess it, is merely a collection of short heads, or rather a kind of syllabus for a set of lectures. There are two books extant, of which the second is so confused and contradictory, that critics are disposed to assign it to a pupil of Agathemerus. The remains of Agathemerus may be seen in the second volume of Hudson's *Minor Geographers*. His first chapter contains a very short sketch of the history of Geography up to that time, with the names of those who had rendered the most eminent services to the science. His sixth chapter treats of the spherical figure of the earth, and what is now called the doctrine of the sphere, &c.

A'GATHIS is the generic name given by botanists to the trees, known in common language by the name of dammar and kawrie pines. These plants belong to the natural order Coniferæ, from all other species of which they are known, firstly, by their broad, lance-shaped, leathery leaves, the veins in which are numerous and nearly parallel, diverging a little at the base, and converging at the apex; and, secondly, by their seeds having a wing on one side instead of proceeding from the end.

The dammar pine (*agathis loranthifolia*), or the pinus dammara of Linnæus, is a large tree found on the very summits of the mountains of Amboyna, Ternate, and in many of the Molucca Islands. When young it has something of the aspect of a young cedar, the wood of which it is said to resemble. It is occasionally cultivated in the hot-houses of curious persons; but is of little value except for its resin, which, when pure, is white, clear, and brittle as glass, but in time becomes amber coloured.

Its timber is represented to be light and of inferior quality, wholly unfit for any situation exposed to wet, but answerng tolerably well for in-door purposes.

The kawrie pine (*agathis Australis*) grows only in New Zealand, in the forests of which it attains a considerable height, with a straight clean stem, which, from its lightness and toughness, has been found well calculated for the masts of ships. It is distinguished from the dammar pine by its narrower and more acute leaves, and by its more rapid mode of growth.

AGA'THOCLES, a Syracusan of low extraction, who became ruler of Syracuse, and great part of Sicily. The principal events in his life range between the years 330 and 289 B.C. He was the son of a potter, and is said to have worked at his father's trade. He was remarkable for beauty, strength, and capacity for enduring labour. In the outset of life, he belonged to a band of robbers; afterwards he served as a private soldier, and in that capacity gained the favour of a patron named Damas, who, being chosen general of Agrigentum, advanced him to the rank of chiliarch, or commander of a thousand men. On the death of Damas, who bequeathed his great wealth to his wife, Agathocles married the widow, and became one of the richest citizens of Syracuse. In this state of his fortune, he distinguished himself by his eloquence in the assembly of the people. But his conduct now was as seditious, as his former life had been profligate. Not content with wealth and popularity, he returned to his early habits, and committed continual acts of piracy against his countrymen.

The constitution of Syracuse, as established by Timoleon, was democratical: but, in the outset of Agathocles' political life, the aristocratical party, headed by Sosistratus, a personal enemy of his own, drove him into exile; and he retreated into Italy, where for some time he lived as a soldier of fortune. The restoration of democracy, and the banishment of Sosistratus and his friends, enabled him to return. The Carthaginians interfered in behalf of these new exiles; and a war ensued, in which Agathocles bore a distinguished part: but he was suspected of aiming at the tyranny, and was a second time compelled to quit Syracuse. In banishment, he collected an army which overawed both Carthage and Syracuse. After frequently defeating the troops of the former, he was recalled, under the pledge of an oath that he would attempt nothing against the democracy; and he was chosen general and protector, for the ostensible purpose of reconciling or putting down faction. Strong in the support of his own mercenary troops, united with some of the poorest and most desperate of the citizens, he proceeded to arrest and execute by military process the leaders of the aristocratical party, and gave up their adherents to the fury of his soldiery. In the massacre which took place, four thousand persons are said to have been murdered, and six thousand to have fled. The wives and children of the latter, those of them who were unable to accompany the fugitives, fell victims to the soldiery.

Agathocles now professed to have fulfilled his duty in clearing the city of the oligarchy, and declared his intention of retiring into private life: but he knew that the partners of his crimes could not maintain themselves without his countenance. At their call he consented to retain his office, on condition of holding it without a colleague (B.C. 317). He did not assume the state of a monarch, but exercised the powers of the most absolute king, with the title of *autocrator*, that is, *ruler according to his own pleasure*. He had risen as the champion of the poor; and he fulfilled his former promises by the abolition of debts and the distribution of lands. His whole career shows him to have been a bold bad man: but his government was able, and in quiet times not severe. It was not till the jealousy of the discerning rendered his situation difficult, or his unbounded ambition prompted him, that he incurred universal hatred by the renewal of sanguinary acts. He aimed at the dominion of the whole island; and succeeded in reducing all except the subjects of Carthage. But the Carthaginians made a strong effort to crush him, and they nearly succeeded. He was defeated with great slaughter (B.C. 309), his subjects nearly all revolted, and a siege being expected, he was obliged to shut himself up in Syracuse. In the following year he adopted the bold plan of carrying the war with his whole disposable force into Africa: but money was required for this purpose; and his contrivance for raising it seems borrowed from the habits of his early life. He offered to let those who feared the hardships of a siege retire from Syracuse, and he sent an armed force after them to plunder and murder those who availed themselves of the permission. By this atrocious act he at once gained supplies, and revenged himself upon his enemies.

On his first landing in Africa, the bold measure of Agathocles appeared to prosper. He burnt his ships, that his soldiers might have no opportunity of retreat, and no hope but in victory. He advanced inland, took several towns, defeated a powerful Carthaginian force sent to oppose him, and threw Carthage itself into great alarm. Meanwhile the Carthaginians prosecuted in vain the siege of Syracuse: but a new danger threatened the rule of Agathocles, from the powerful city of Agrigentum; which profited by the exhaustion both of Carthage and Syracuse to invite the Sicilians to shake off the dominion of both. Agathocles returned home in haste, and reduced some of the revolted cities. But the forces of the rest, united under the command of Deinocrates, a Syracusan, formerly general of the Greeks in the Carthaginian army, proved too strong for him. Moreover, his presence was again required in Africa, where the Carthaginians had repaired their losses, and regained their ascendancy. In this dilemma, he resorted to one of those infamous measures which disgrace his talents as a soldier and statesman. He saw the probability that the Syracusans might call in Deinocrates in his absence. A public festival took place shortly before his intended return to his African army. Being a man of popular manners, he affected to mix gaily in the mirth, and by plying the people with wine, encouraged them to open their hearts. By this insidious device, he ascertained who were his friends and who his enemies, and put to death the chief men of the latter, to the number of five hundred.

Whether in Sicily or Africa, the affairs of Agathocles never prospered in his absence. He was received on his return to the latter country by a mutiny among his troops, in consequence of his son Archagathus having been dilatory in furnishing their pay. On that occasion his popular eloquence saved him: he harangued the soldiery, saying that they must get their pay from the enemy, and that the booty, like the victory, should be in common. But the necessity of recovering the good will of his army betrayed him into imprudencies. He attacked the Carthaginians unadvisedly, and lost the battle, and a large portion of his men. He was compelled to retreat to his camp, where he saw that his rashness had set the soldiers against him, and he had reason to fear that they would renew the mutiny on account of the arrears of pay. He therefore fled in the night, accompanied by Archagathus. They were pursued, and the son was taken: the father, with better fortune, reached the ships in which he had returned from Sicily, and escaped. All his sons were murdered by the enraged soldiers, who then made terms with the Carthaginians. Agathocles avenged himself in kind on the murderers of his sons, by slaying the kindred of those who had served with him in Africa.

On his return to Sicily, he found that a large portion of the troops, and several of the cities, had gone over to Deinocrates, who himself aspired to sovereignty. He therefore made peace with the Carthaginians, and commenced a war against the exiles; whom he defeated, and treacherously slew to the number of seven thousand, after they had laid down their arms under assurance of safety. But he received Deinocrates with favour, and appointed him his general; nor did any enmity thenceforth occur between them, although both were equally ambitious and faithless. When all questions were settled between himself, the Carthaginians, and Deinocrates, Agathocles found it easy to reduce the revolted cities of Sicily. But he was not of a temper to be contented within the narrow boundaries of the island. He undertook an expedition into Italy against the Bruttii, laid the Lipari islands under contribution, and plundered their temples, but was obliged, by severe illness, to leave his main designs uncompleted. While in Italy, he made himself master of Crotona, and on the whole, with mingled prosperity and adversity, maintained the character of a mighty potentate, but a severe scourge of mankind. The final object of his ambition was to render Sicily a great naval power; and he had advanced far and successfully in the prosecution of this attempt, when he died, by one account, in consequence of a miserable and wasting illness,—by another, in consequence of poison administered by Mænon, one of his associates, in concert with his own grandson. His death took place in the year 289 B.C., at the age of seventy-two, after a reign of twenty-eight years.

AGATHODÆ'MON, of Alexandria, a map-maker, and apparently the author of the maps found in the oldest MSS. of the geography of Claudius Ptolemæus. There can be no doubt that Ptolemy's work was accompanied by maps; and indeed it is impossible that a tabular system of Geography, like his, could be without them. Maps on plates of copper are mentioned by Herodotus, who wrote above 500 years before Ptolemy. But, as we know nothing at all about the age of Agathodæmon, we cannot conclude, as some do, that he constructed Ptolemy's maps for him. It is more likely that he was a later editor or amender of them. In the Vienna and Venetian MSS., the following note in Greek is found at the end of the maps:—'According to the eight books of the geographical works of Claudius Ptolemæus, Agathodæmon of Alexandria delineated the whole earth.' It has been inferred from this that Agathodæmon was a contemporary of Ptolemy. But this does not seem to be quite conclusive. The shape which Agathodæmon gave to the different countries of the earth, maintained its ground on modern maps till the system of regular surveys became in use: and indeed till of late years, many features of our maps were only the traditional delineations of the old map-makers of Alexandria. [See Schoell, vol. ii. Heeren. *De fontibus Ptolemæi*. PTOLEMÆUS, CLAUDIUS.]

AGA'VE, in Botany, comprehends those plants which gardeners call American aloes. It consists of species producing clusters of long, stiff, fleshy leaves, collected in a circle at the top of a very short stem, and bearing flowers in a long terminal woody scape. With doryanthes and yucca it forms in the natural order Amaryllideæ an instance of high developement both in vegetation and fructification, compared with what is more generally characteristic of that tribe. If a crinum or an amaryllis had the stem elongated into a woody trunk, instead of being contracted into a short disk, lying at the bottom of a scaly bulb, the affinity between them and agave would at once be obvious.

There are many species of this genus, one only of which requires to be mentioned.

Agave Americana, or the American aloe, is a plant which, when full grown, has a short cylindrical woody stem, which is terminated by hard, fleshy, spiny, sharp-pointed, bluish green leaves, about six feet long, and altogether resembling those of the arborescent aloes. Each of these leaves will continue to exist for many years, so that but a small number have withered away by the time the plant has acquired its full maturity. It is commonly supposed that this occurs only at the end of one hundred years; but this, like many other popular opinions, is an error; the period at which the agave arrives at maturity varying, according to circumstances, from ten to fifty, or even seventy years. In hot or otherwise favourable climates, it grows rapidly and soon arrives at the term of its existence; but in colder regions, or under the care of the gardener, where it is frequently impracticable to attend to all the circumstances that accelerate its developement, it requires the longest period that has been assigned to it. Having acquired its full growth, it finally produces its gigantic flower stem, after which it perishes. This stem sometimes is as much as forty feet high, and is surrounded with a multitude of branches arranged in a pyramidal form, with perfect symmetry, and having on their points clusters of greenish yellow flowers, which continue to be produced for two or three months in succession. The native country of the American aloe is the whole of America within the tropics, from the plains nearly on a level with the sea, to stations upon the mountains at an elevation of between 9000 and 10,000 feet. From these regions it has been transferred to almost every other temperate country; and in Italy, Sicily, and Spain, it has already combined with the date and the palmetto to give a tropical appearance to European scenery.

[Agave.]

Independently of its beauty and curiosity, this plant is applicable to many useful purposes. Its sap may be made to flow by incisions in the stem, and furnishes a fermented liquor called by the Mexicans *pulque;* from this an agreeable ardent spirit, called *vino mercal*, is distilled. The fibres of its leaves form a coarse kind of thread; the dried flowering stems are an almost imperishable thatch; an extract of the leaves is made into balls, which will lather water like soap; the fresh leaves themselves cut into slices are occasionally given to cattle; and finally the centre of the flowering stem split longitudinally is by no means a bad substitute for a European razor strop, owing to minute particles of silica forming one of its constituents.

AGE. In legal acceptation, a person is said to be of age when he has passed those periods of his life at which he is supposed to have acquired sufficient discretion to enable him to do certain acts and enter into certain contracts, of which, before those periods have arrived, he is presumed to be incapable by reason of the immaturity of his understanding. The common law of England appoints certain specific times in the life of a man or woman before either is permitted to form contracts and incur municipal obligations. Thus, at the age of twelve years, a man may take the oath of allegiance; at fourteen, which for many purposes is considered the age of discretion, a person of either sex may choose a guardian, and may also, according to ancient authorities, be a witness in courts of justice; in the latter case, indeed, the rule is at the present day considerably relaxed, for children of much tenderer years are frequently permitted to give evidence, having been previously found competent upon examination to understand the nature of an oath. A female at the age of twelve years, and a male at the age of fourteen years, may make a valid will of personal estate, if proved to have had sufficient understanding at the time the will was made; but it is particularly provided by statute that no person under the age of twenty-one years shall make a will of lands. At the age of seventeen years, a person of either sex may be an executor or executrix.

With respect to matrimony, a woman may by law consent to marriage at twelve, and a man at fourteen years of age: though, by several statutes, parties under the age of twenty-one years cannot actually marry without the express consent of their respective parents or guardians. [See MARRIAGE.] The age of twenty-one years is, for most civil purposes, the full age both of a man and woman, at which period persons of either sex may enter into the entire possession of their real and personal estates, may manage and dispose of them at their discretion, and form contracts and engagements of all kinds upon their own account. A man cannot, however, be ordained a priest till twenty-four, nor be a bishop till thirty years of age.

With respect to criminal offences, the law of England regards the age of fourteen years as the age of discretion, at which the human mind is competent to distinguish between right and wrong; a person of either sex, therefore, who has attained that age is liable to prosecution and punishment for crimes. Under the age of seven years, a child is not in any case responsible by law for an offence committed by him; but, above that age, and under the age of fourteen years, if it clearly appears that a child is conscious of the nature and wickedness of the crime he commits, he may be tried and punished for it. A very singular instance is related by Mr. Justice Foster of a boy nine years old, who, under circumstances of malice and premeditation, had killed his companion, and hidden the dead body with much care and cunning, and who was tried for murder, and found guilty. The case was afterwards considered by the twelve judges, who thought that the circumstance of hiding the dead body proved the fact of consciousness of guilt, and therefore a capacity of distinguishing good from evil, inconsistent with the presumption of innocence arising from the tender age of the child; and they unanimously agreed that he was a proper subject for capital punishment. Foster's *Crown Cases*, p. 72. For more particular information on the whole of this subject, see INFANT.

AGE (Physiology). The term of human existence is divisible into distinct periods, each of which is distinguished by characters peculiar to itself. These characters, as far as they are external, are obvious to every one; but these external characters depend on internal states which are not obvious, and which have been discovered only by careful and persevering research. And the curious and interesting facts which those researches have disclosed, show that the different epochs into which life is divided are not arbitrary distinctions, but arise naturally out of constitutional differences in the system, dependent on different physiological conditions. The natural epochs of human life are six, namely, the period of infancy, childhood, boyhood or girlhood, adolescence, manhood or womanhood, and old age. The space of time included in the first four of these periods is fixed. In all persons after the lapse of a certain number of years, a definite change in the system uniformly takes place, in consequence of which the peculiarities which distinguish one period give place to those which characterise the succeeding. Thus the period of infancy, commencing at birth, extends to the end of the second year, the point of time at which the first dentition is completed: the period of childhood, commencing at the close of the second year, extends to the termination of the seventh or eighth year, the point of time at which the second dentition is completed: the period of boyhood or girlhood extends from the seventh or eighth year to the commencement of the age of puberty; that is, in general, in this country, in the female, from the twelfth to the fourteenth year, and for the male, from the fourteenth to the sixteenth year: the period of adolescence extends from the commencement of the period of puberty to the twentieth year of the female, and the twenty-fourth of the male: the period of womanhood extends from the twentieth, and of manhood, from the twenty-fourth year, to an age neither determined nor determinable with any degree of exactness; because the point of time at which mature age lapses into old age differs in every individual. It differs in many cases by a considerable number of years; and it differs according to primitive constitution, to the management of early infancy and childhood; according to regimen, exercise, occupation, physical and mental, and the several other circumstances included under the general term '*mode of life*.'

It is an observation familiar to every one, that some persons are older at fifty than others are at seventy, while instances every now and then occur in which an old man who reaches his hundredth year retains as great a degree of juvenility as the majority of those who attain to eighty. The period extending from the age of thirty or forty to that of extreme old age is then the only variable period in the term of human existence; the only period not fixed by limits which it is beyond the power of man materially to extend or abridge—a fact abounding with the most interesting practical suggestions.

The changes which take place in the system at the different epochs of life consist of changes in the physical condition of the body which it will be useful briefly to trace. These changes are intimately connected with, and are mainly dependent on the operation of a principle of consolidation, the influence of which, commencing at the first moment of existence, continues, without intermission, until the last moment of life. By this principle the body is changed, first from the state of a fluid into that of a solid; and next, from a soft and tender solid, into a solid which slowly, imperceptibly, but nevertheless uninterruptedly, increases in firmness and hardness.

When first the human embryo becomes distinctly visible, it is almost wholly fluid, consisting only of a soft, gelatinous pulp. In this gelatinous pulp solid substances are formed, which gradually increase and are fashioned into organs. These organs, in their rudimentary state, are soft and tender, but, in the progress of their development, constantly acquiring a greater number of solid particles, the cohesion of which progressively increases, the organs at length become dense and firm. As the soft solids augment in bulk and density, bony particles are deposited, sparingly at first and in detached masses, but accumulating by degrees: these, too, are at length fashioned into distinct osseous structures, which, extending in every direction, until they touch at every point, ultimately form the connected bony frame-work of the system. This bony fabric, like the soft solid, tender and yielding at first, becomes by degrees firm and resisting, fitted, as it is designed, to be the mechanical support of the body, and the defence of all the vital organs.

While the osseous system is thus extending in every direction, and everywhere increasing in compactness, the progressive consolidation of the body is equally manifest in all the tissues which are composed of the cellular membrane as well as in all those which possess a fibrous nature. The membranes, the ligaments, the tendons, the cartilages, gradually increase in firmness and elasticity, and proportionally diminish in flexibility and extensibility; and this change takes place, to a considerable extent, in the muscular fibre also, as is manifest from the toughness of the flesh of animals that are used for food, the degree of which every one knows is in proportion to the age of the animal; and from the conversion in extreme old age, in many parts of the body, of muscle into tendon, a denser material being substituted for the proper muscular fibre.

The steady and increasing operation of the principle of consolidation is still more strikingly manifest in the deposition, as age advances, of bony matter in tissues and organs to which it does not naturally belong, and the functions of which it immediately impairs and ultimately destroys. The textures in which these osseous depositions most commonly take place are membranes, tendons, cartilages, and the coverings of the viscera, but above all the coats of the blood-vessels, in consequence of which these highly flexible, elastic, and moveable organs become firm, rigid, and immoveable. But even when not converted into bone, several of these structures lose their flexibility with advancing age, and acquire an increasing degree of rigidity. This is strikingly manifest in all the parts of the apparatus of locomotion; in the joints, the mechanical contrivances for facilitating motion, and in the muscular fibre, the generator of the power by which motion is produced. The joints in old age are less pliable, less elastic, and more rigid than in youth; first, because the ligamentous and cartilaginous structures of which they are composed are more dense and firm; and secondly, because the oily matter which lubricates them, and which renders their motions easy and springy, is secreted in less quantity, and of inferior quality. Induration and proportionate deterioration take place then in the muscular fibre, the origin of the motive power, and in the joint the instrument by which the operation of the motive power is facilitated; and consequently the movements become slower, feebler, less steady, less certain, and less elastic.

But among all the changes induced in the body by the progress of age, none is more remarkable, or has a greater influence in diminishing the energy of the actions of the economy, and in causing the ultimate termination of all those actions in death, than the change that takes place in the minute blood-vessels. The ultimate divisions, or the smallest branches of the arteries and veins, the capillary vessels, as they are termed, are exceedingly abundant in the early periods of life, and are as active as they are numerous. The capillary arteries, the masons and architects of the system, by the agency of which all the structures are built up, and all the parts of the body grow and are developed, are numerous and active in the early stages of life, while they are carrying on and completing the organization of the frame. But from infancy to childhood, from childhood to youth, from youth to maturity, and from maturity to old age, the number and the activity of these vessels progressively diminish. Their coats, like other soft solids, increase in density and rigidity; their diameter contracts, many of them become completely impervious and ultimately disappear. The diameter of the capillary veins, on the contrary, enlarges. The coats of the veins, originally thinner than those of the arteries, instead of thickening and contracting, seem rather to grow thinner and more dilatable; hence their fulness, their prominence, their more tortuous course, and their greater capacity. At the two extreme periods of life the quantity of blood contained in these two sets of vessels is completely inverted. In infancy, the proportion of blood contained in the capillary arteries is greater than that contained in the capillary veins; in youth, this disproportion is diminished; at the period of maturity, the quantity in one set, nearly if not exactly balances that in the other; in advanced age, the preponderance is so great in the veins, that these vessels contain probably two-thirds of the entire mass. This difference in the distribution of the blood, at the different epochs of life, affords an explanation of several important phenomena connected with health and with disease. It shows, for example, why the body grows with so much rapidity at the early periods of life; why it remains stationary at the period of maturity; why it diminishes in bulk as age advances; why a plethoric state of the system affects the arteries in youth, the veins in age; why hæmorrhage, or a flow of blood, is apt to proceed in the young from the arteries, and in the aged from the veins; and so on.

The growth of the heart does not keep pace with the extension of the sanguiferous system, nor does its force increase with the augmenting density and resistance of the solids; hence there is a disturbance of the balance between the forces of propulsion and of extension which increases with advancing age; the diminished energy of the heart being indicated by the languor and slowness of the pulse, often not exceeding fifty pulsations in a minute, and sometimes sinking even lower than this. Hence, not only is less blood sent to the several organs, but that which is sent is less completely acted upon by the air in respiration on account of the diminished quantity which is transmitted through the pulmonary system of vessels; hence, the diminution of all the secretions, and hence, finally, the failure of the function of digestion, the source of the materials from which the blood itself is prepared and its losses replenished.

Upon the whole, then, it is clear that two great changes take place in the physical condition of the body in the progress of age; first, a gradual diminution in the quantity of the fluids, both of the entire mass contained in the system, and of the proportionate quantity contained in each organ: and, secondly, a progressive augmentation and induration of the solids. With this change in the physical condition of the body is uniformly combined a no less important change in its vital action. Progressively and proportionally as the solid parts increase in density and rigidity, they decrease in irritability and mobility; that is, they are less sensible to the influence of stimulants, and the power of contraction resident in the muscular fibre is less excitable. Now the knowledge of this two-fold modification of the system suggests practical applications of the greatest importance in the management of health, in the prevention of disease, in securing the attainment of perfect maturity, corporeal and mental, and consequently in promoting a general extension of the term of life.

In each of the epochs of life the health is peculiar; the diseases to which each is prone have also a specific character. A degree of energy in the vital actions, constituting a state of healthy vigour in one period, may be destructive violence in another; and a degree of intensity in the physical agent upon which those actions depend, merely sufficient to produce moderate excitement in one, may produce fatal stimulation in another.

It has been shown, that in the human infant by far the greater proportion of its body consists of fluids; and that this state of the system is characterized by an extreme degree of irritability and mobility. The capillary arteries, especially, are not only more numerous in this age than in any other, but they are also far more irritable; far more easily and dangerously excitable. And this is most particularly the case with the capillary arteries of the stomach and intestines; with those of the lungs; with those of the external skin; with those of the spinal cord and brain: and a consideration of the manner in which these vessels are acted on, for example, by aliment and by temperature, two agents which exert the most important influence over the health and life of the infant, will suffice to illustrate the value of knowledge of this kind.

The chief organ by which the function of digestion is performed is the mucous membrane that lines the stomach and intestines. Food, when in contact with the inner surface of this membrane, acts upon it as a stimulus and excites it to the performance of its office. Now so irritable is this membrane in the infant, that it can bear the contact only of one kind of aliment, namely, the milk formed by the mother. For this food, and only for this food, has nature specially adapted the organ, and the adaptation of this food to this organ is in its turn equally specific; and this relation cannot be disturbed or disregarded without preventing the due performance of the function, and thereby endangering health and life. Even the blandest substances, the milk of other animals, which, at a more advanced age, can be readily converted into nutriment, over excites the delicate digestive organ of the infant, producing first grievous irritation in the system, and, ultimately, exhaustion and death. From large experience it is found, that of the infants who are deprived of this their natural nourishment, not more than one in seven reaches the more advanced periods of life. Without doubt circumstances may justify a mother in abandoning her infant, but she ought, at least, to know the extent of the sacrifice she makes when she withholds from it the only food by which it can live; she ought to be fully aware that by this act she does abandon it.

Cold acts upon the lining membrane of the air-passages of the lungs, as injuriously as improper diet upon the mucous surface of the alimentary canal; and it also acts most energetically and deleteriously upon the whole external surface of the skin. The new-born infant has been kept for months in a constant and unvaried warmth. Both its external and its internal surfaces have been completely shielded from the contact of foreign bodies. But at the moment of birth its condition is wholly changed; both surfaces are fully exposed to agents, to the influence of which it is acutely sensitive. Air surrounds the external skin and rushes to the lung and expands it; cold acts simultaneously and powerfully on both organs. If the cold be severe, or if the changes of temperature be great and rapid, inflammation is sure to be excited in the *lung;* and this is one of the chief sources of the mortality of infancy. The injurious action of cold upon the *external* surface is two-fold; first, upon the vessels, and nerves of the skin; and, secondly, upon the vessels, and nerves of the internal organs; for the cold, constringing the external vessels, causes the blood diffused over this extended surface to rush to the internal parts, and especially to the brain, in which it often produces dangerous and fatal disease. The mother should never forget that a degree of cold which the child can bear with impunity may excite a mortal inflammation in the infant; and that an intensity of cold which may only invigorate the adult may kill the child. Were an accurate record kept of the number of children annually destroyed in England by improper exposure to cold, the sum would fill the country with dismay. The proper management of the period of infancy consists essentially in causing the infant to subsist on the milk of the mother only, at least during the first months; in keeping it in an equal and moderately warm temperature; in surrounding it by night as well as by day, when asleep as well as when awake, by a large bulk of fresh air; in frequently washing the entire surface of its body first with warm, then with tepid, and towards the latter months of the period, in perfectly cold water, followed immediately by vigorous friction.

There is one caution in relation to medicine which cannot be too frequently kept in view. The same state of the system which renders the infant so susceptible to the influence of ordinary physical agents, renders it at least equally susceptible to the influence of irritant drugs; and especially of those which act primarily on the mucous surface of the alimentary canal, or on the nervous system. The regulation of the bowels by aperient medicine is often necessary; but a tea-spoonful of castor oil, or from four to six grains of magnesia, is all that the mother or the nurse should venture to give unless under the superintendence of a medical friend. The aperients often given are far too irritating; while of an opposite class of medicines it may be truly said, that every preparation of opium, even in the very minutest dose, is, in the early period of infancy, highly dangerous. Opiates act on the nervous system of the infant most energetically and banefully, and many is the new-born infant whose life is suddenly cut short by quack medicines, soothing as they are called, (and soothing indeed they are!) which often contain a concentrated dose of a powerful narcotic, and which, according to the dose, excites either an inflammatory action of the capillaries of the brain, or an accumulation of blood in the cerebral vessels, one or other of which co-operating with the irritable state of the system, for the quieting of which the opiate was given, produces the quiet of death.

From the seventh month to the end of the second year, the consolidation and development of all the tissues and organs proceed with rapidity. The process of ossification advances: the soft solids grow firmer: the muscles enlarge in bulk and increase in strength: the brain especially becomes more developed, and its functions more active and more extended: consequently, sensation not only increases in acuteness and exactness, but embraces a wider range; hence perception becomes more perfect; the phenomena of mind appear; speech commences; affection is generated; passion induced; moral habits, good or bad, acquired, each of which events introduces into the economy a new power which ever afterwards exerts over it a prodigious influence for good or for evil, for pleasure or for pain, for health or for sickness.

As infancy passes into childhood, the brain, the spinal cord, the bones, the muscles, and the other soft solids, progressively acquire bulk, cohesion, firmness, and strength. All the capillaries of the system still continue exceedingly active and highly irritable. For the support of their action a large supply of nutritious food is indispensable. There is scarcely an organ that is not still to be completed, and the magnitude of which is not to be augmented. Aliment is the material by which these results are to be effected, and the consequences of privation at this period are truly deplorable. Not only is the growth of the body checked for a time, but the physical and mental constitutions are irreparably injured. From the beginning to the end of this period every effort should be directed to the development and invigoration of the physical, and the formation and direction of the moral powers; as yet the development of the intellectual is of little consequence. The health, the strength, the longevity, the physical, the intellectual, the moral qualities, the usefulness or the mischievousness, the happiness or the misery of the future man, depend essentially on the management of these two periods of human existence. For this reason we have endeavoured to direct attention to their paramount importance, and to the value of that knowledge which teaches in what their proper management consists. We shall have other occasions to return to the subject, and to state more in detail the regimen proper to these earlier, as well as to the more advanced stages of human life. In the mean time we earnestly intreat the attention of WOMEN to subjects of this class. The health and life, and what is of much more importance, the virtue and happiness of their children are far more deeply involved in the soundness of the knowledge they acquire on subjects of this kind, than they have hitherto been taught to believe.

AGE OF LIFE. [See MORTALITY.]

AGE OF ANIMALS. It is often a matter of great importance to possess some means of determining the age of organized bodies, both in the animal and vegetable kingdoms. It is to be regretted, however, that for our guidance in these matters we possess but few general principles derived from well-regulated observations and experiments. As far as regards animals, indeed, it has been said, that the duration of life is generally between seven and eight times the period which elapses from birth till they become adult; but this rule, besides being vague and indefinite, is quite useless and inapplicable in practice, because it affords no scale of gradation which would enable us to ascertain the precise age of individuals, the only inquiry of real importance or of practical application to the interests of society. More certain and scientific principles are derived from observing the growth and decay of the teeth; and if we were acquainted with the various phenomena which attend the development of these organs in all quadrupeds, there is no doubt but that we should be enabled to obtain general and, in a great measure, certain rules, not only applicable to individual cases, but likewise to the speculative philosophical problem of the duration of life in each separate species. At present, however, we do not possess a series of observations sufficiently extensive to enable us to solve this problem generally; and we shall, therefore, confine ourselves to the few individual cases in which it has been determined, and which relate only to the most important domestic animals.

The age of the horse is known principally by the appearance of the incisive teeth, or, as they are technically called, the nippers. Of these there are six in each jaw, broad, thin, and trenchant in the foal, but with flat crowns marked in the centre with a hollow disk in the adult animal. The foal or milk teeth appear fifteen days after birth; at the age of two years and a half the middle pair drop and are replaced by the corresponding permanent teeth; at three years and a half the two next, one on each side, fall and are likewise replaced; and at the age of four years and a half the two external incisors of the first set drop and give room to the corresponding pair of permanent teeth. All these permanent nippers, as we have already observed, are flattened on the crown or upper surface, and marked in the centre with a circular pit or hollow, which is gradually defaced in proportion as the tooth wears down to a level with its bottom. By the degree of this detrition or wearing of the teeth, the age of the animal is determined, till the eighth year, at which period the marks are generally effaced; but it is to be observed that the external incisors, as appearing a year or two after the intermediate, preserve their original form proportionally for a longer period. After the eighth year the age of the horse may be still determined for a few years longer by the appearance and comparative length of the canine teeth or tushes. These, it is true, are sometimes wanting, particularly in the lower jaw, and in mares are rarely developed at all. Those of the under jaw appear at the age of three years and a half, and the upper at four; till six they are sharp-pointed, and at ten they appear blunt and long, because the gums begin about that period to recede from their roots, leaving them naked and exposed; but after this period there are no further means of judging of the horse's age, excepting from the comparative size, bluntness, and discoloured appearance of the tushes. The duration of the horse's life seldom surpasses thirty years, though there have been instances recorded in which it is said to have extended to double that period.

In horned cattle the age is indicated more readily by the growth of these instruments than by the detrition and succession of the teeth. The deer kind, which shed their horns annually, and in which, with the single exception of the rein-deer, they are confined to the male sex, have them at first in the form of simple prickets without any branches or antlers; but each succeeding year of their lives adds one or more branches, according to the species, up to a certain fixed period, beyond which the age of the animal can only be guessed at from the size of the horns and the thickness of the burr or knob at their roots, which connects them with the skull. In the common stag, the pricket or first horn falls during the second year of the animal's life, and is replaced by one with a single antler, and called, from this circumstance, the fork. This again falls during the third year, and is replaced by the third horn, which, as well as the fourth or following pair, have commonly three or four, and sometimes even five branches. In the same manner the number of antlers goes on increasing till the eighth year of the animal's life, beyond which period they follow no fixed rule, though they still continue to increase in number, particularly towards the summit of the horn, where they are often grouped in the form of a coronet, and in this state they are called royal antlers. The fallow-deer, the roe-buck, and others of this genus, present similar phenomena; the number of the antlers increases according to certain fixed rules up to a certain period, beyond which the age can only be determined, as in the stag, by the comparative size and development of the burr and shaft, or that part of the horn from which the antlers grow. In the former species, the prickets of the second year are replaced by horns bearing two antlers, and already beginning to assume the palmated form which distinguishes them from the antlers of most other deer. Afterwards this palm increases in breadth, and assumes an indented form on the superior and posterior borders: these are the fourth horns, which are shed in the animal's fifth year, and are replaced by others in which the palm is cloven or subdivided irregularly into distinct parts, so that the horns of old animals frequently assume a great diversity and singularity of form. From this period the horns begin to shrink in size, and are even said to end in becoming simple prickets as in the first year.

The horns of oxen, sheep, goats, and antelopes, which are hollow and permanent, are of a very different form, and grow in a different manner, from those of the deer kind. These, as is well known, consist of a hollow sheath of horn, which covers a bony core or process of the skull, and grows from the root, where it receives each year an additional knob or ring, the number of which is a sure indication of the animal's age. The growth of the horns in these animals is by no means uniform through the whole year, but the increase, at least in temperate climates, takes place in spring, after which there is no further addition till the following season. In the cow kind, the horns appear to grow uniformly during the first three years of the animal's life; consequently, up to that age they are perfectly smooth and without wrinkles, but afterwards each succeeding year adds a ring to the root of the horn, so that the age is determined by allowing three years for the point or smooth part of the horn and one for each of the rings. In sheep and goats the smooth or top part counts but for one year, as the horns of these animals show their first knob or ring in the second year of their age; in the antelopes they probably follow the same rule, though we have very little knowledge of their growth and development in these animals.

There are very few instances in which the age of animals belonging to other classes can be determined by any general rules. In birds it may be sometimes done by observing the form and wear of the bill; and some pretend to distinguish the age of fishes by the appearance of their scales, but their methods are founded upon mere hypothesis and entitled to no confidence. The age of the whale is known by the size and number of laminæ of whale-bone, which increase yearly, and, if observation can be relied upon, would sometimes indicate an age of three or four hundred years for these animals.

AGE OF TREES. Every thing connected with the growth of timber-trees, their duration, and the causes which conduce to their decay, bears so directly upon points not only of general interest, but of great practical importance, that we have thought it advisable to devote an article to its separate consideration.

Plants, like animals, are subject to the laws of mortality, and, in many cases, have the period of their existence determined by nature with as much exactness as that of an insect. But at the same time, not only their structure, but their vital actions are so peculiar, that little analogy can, in any case, be traced between the more perfect of them and the animal world, and a very large proportion appear to be capable of an almost indefinite period of existence, if it were not for accidents and disease, independent of old age.

It is chiefly to annual and biennial plants that what may be called a precise period of duration is fixed; a period determined by the production of their fruit, and not capable of being prolonged beyond that event, except by artificial means. Dismissing all such from our consideration, the remainder of the more perfect part of the vegetable kingdom, whether herbaceous, or shrubby, or arborescent, consist of plants which may be classed under two principal modes of growth.

One of these modes is to increase, when young, in diameter, rather than in length, until a certain magnitude is obtained, and then to shoot up a stem, the diameter of which is never materially altered. The addition of new matter to a trunk of this kind takes place by the insinuation of longitudinal fibres into the *inside* of the wood near the centre; on which account such trees are called ENDOGENOUS; they also bear the name of *Monocotyledons.*

The other mode is, from the beginning, to increase simultaneously in length and diameter, but principally in length. The addition of new matter to a trunk of this kind takes place by the insinuation of longitudinal fibres into a space beneath the bark, and on the *outside* of the wood near the circumference; on which account such trees are called EXOGENOUS; they also bear the name of *Dicotyledons.*

Some modifications of these two modes are known to exist, but it would only confuse the subject if they were adverted to on this occasion.

To the first of these classes belongs the palm-tribe, and some other tropical trees. There is scarcely any well-attested evidence of these plants ever acquiring any considerable age. It has, indeed, been supposed, that certain Brazilian cocoa-nut palms may be from 600 to 700 years old, and that others probably attain to the age of something more than 300 years. But the method of computing the age of palms, which is either by the number of rings externally visible upon their rind between the base and the summit of the stem, or by comparing the oldest specimens, the age of which is unknown, with young trees of a known age, is entirely conjectural, and not founded upon sound physiological considerations; besides which, the date-palm, which is best known to Europeans, does not at all justify the opinion that palms attain a great age; the Arabs do not assign it a greater longevity than from two to three centuries. Independently of this, the mode of growth of such endogenous trees as palms seems to preclude the possibility of their existing beyond a definite period of no great extent. The diameter to which their trunk finally attains is very nearly gained before they begin to lengthen, and afterwards all the new woody matter, which every successive leaf *necessarily* produces during its developement, is insinuated into the centre. The consequence of this is, that the woody matter previously existing in the centre is displaced and forced outwards towards the circumference; as this action is constantly in progress, the circumference, which in the beginning was soft, becomes gradually harder and harder, by the pressure from within outwards, till at last it is not susceptible of any further compression. After this has occurred, the central parts will gradually solidify by the incessant introduction by the leaves of new wood which thrusts outwards the older wood, till at last the whole stem must become equally hard, and no longer capable of giving way for the reception of new matter; *for what has once been formed always remains, and is never absorbed by surrounding parts.* As soon as this occurs, and occur it must in trunks which rarely exceed a foot, and, perhaps, never a foot and half in diameter, the tree will perish; because its vitality is dependent upon the full action of all the functions of the leaves, and the cessation of one is the cessation of all. It is for these reasons that we feel justified in considering it probable that endogenous trees, such as palms, attain no considerable age, and that the duration of their existence must be absolutely fixed in each species by the power they may respectively have of permitting the descent of woody matter down their centre.

But in exogenous trees, it is quite the reverse: to their existence no limited duration can be assigned; on the contrary, there is nothing physically impossible in the notion that some individuals now existing may even have been silent witnesses of the Noachian deluge. In consequence, first, of the new woody matter which is constantly formed by the leaves of such trees being insinuated beneath the bark near the circumference of their trunk, and, secondly, of the bark itself being capable of indefinite distention, no compression is exercised by the new parts upon those previously formed; on the contrary, the bark is incessantly giving way to make room for the wood beneath it, while the latter is, in consequence, only glued, as it were, to what succeeds it, without its own vital powers being in any degree impaired by compression. It is in the newly-formed wood that the greatest degree of vitality resides: in the old wood near the centre life in time becomes extinct; but as each successive layer possesses an existence in a great degree independent of that which preceded it, the death of the central part of an exogenous tree is by no means connected with any diminution of vitality in the circumference. Hence it is that hollow trees are often so healthy; and that trees in the most vigorous state are often found decayed at the heart without any external sign, as timber-merchants frequently discover to their cost. The manner of growth in exogenous trees being such as has been just described, they may be compared to a succession of hollow cylinders increasing gradually in diameter and sheathing one another. This being the case, and the last cylinder having its own independent vitality, it will be apparent that, under circumstances constantly favourable to growth, individuals of this kind may continue to exist to the end of time; for there is no conceivable manner in which their death can be brought about in the absence of accidents; among which would, of course, be classed starvation, arising from the destruction of nutriment in the soil where they grow, and suffocation caused by the obstruction of their respiration, whether by the absence of light or the exclusion of air.

This it is which explains the extreme old age which some trees certainly attain. Of the many remarkable cases upon record, the following are among the more interesting.

At Ellerslie, the birth-place of Wallace, three miles to the south-west of Paisley, stands an oak, in the branches of which tradition relates that celebrated chieftain to have concealed himself with three hundred of his followers. However improbable the latter circumstance may be, it is at least certain that the tree may well have been a remarkable object even at the period assigned to it by tradition, namely, in the beginning of the fourteenth century, and if so, this individual must be at least 700 years old. Its branches are said to have once covered a Scotch acre of ground; but its historical interest has rendered it a prey to the curiosity of the stranger, and its limbs have gradually disappeared till little remains except its trunk.

[The Wallace Oak.]

Many other cases of oaks of extreme old age are recorded, some of which have been estimated at 1500 or 1600 years.

At Trons, in the Grisons, there existed, in 1798, a lime tree which was a celebrated plant in the year 1424, and which, when last measured, was fifty-one feet in circumference. The age of this specimen could not have been less than 580 years.

In the year 1776, there existed in the Palace Garden of Granada some famous cypresses called *Cupresos da la Sultana*, in consequence of some event that occurred in the time of the Moorish kings, at which time they formed a cypress grove. These are thought to have been at least 800 or 900 years old.

The famous sweet-chestnut trees on Mount Ætna, especially those called the *Castagna de' Cento Cavalli*, 180 feet in circumference at the bottom of the trunk, *de Sta. Agatha*, seventy feet in circumference, and *della Nave*, sixty-four feet in circumference, must be of high antiquity; but nothing precise is known upon this point, and it is almost certain that the first mentioned has been in reality formed of five or six trunks grown together.

Equally unknown is the age of an immense oriental plane tree now growing in the valley of Bujukdere near Constantinople, which is 150 feet in circumference, with an internal cavity eighty feet in circumference.

The walnut sometimes attains a prodigious size, consequently a great age. Scamozzi, an Italian architect, mentions his having seen at St. Nicolas, in Lorraine, a single plank of its wood twenty-five feet wide, upon which the Emperor Frederick III. had given a sumptuous feast.

Eight olive trees still exist in the Garden of Olives at Jerusalem, which can be proved by historical documents to have existed anterior to the taking of the city by the Turks, and consequently to be at least 800 years old.

Of ancient yews several authentic instances can be named. At Ankerwyke House, near Staines, is a yew older than the meeting of the English barons at Runnymede, when they compelled King John to grant the Magna Charta.

[The Ankerwyke Yew.]

This tree, at 3 feet from the ground, measures 9 feet 3 inches in diameter; and its branches overshadow a circle of 207 feet in circumference. The yews of Fountain's Abbey, in Yorkshire, are probably more than 1200 years old, and to others an age of from 2500 to 3000 years has been assigned.

Even this degree of antiquity is, however, much less than that of the Baobab trees of Africa, estimated by Adanson at 5150 years; and the deciduous cypress of Chapultepec in Mexico, which the younger De Candolle considers still older.

The way in which the age of some of these specimens has been computed is twofold. firstly, by comparing them with other old specimens, the rate of growth of which is known; and secondly, by cutting out a portion of their circumference and counting the number of concentric rings that are visible. For in exogenous trees the woody cylinder of one year is divided from the succeeding one by a denser substance, which marks distinctly the line of separation of the two years.

The first of these methods is sufficiently correct to give at least an approximation to the truth, and the latter would be absolutely correct, if one could be quite sure that observers provided against all possible causes of error. But it has been shown, (see Dr. Lindley's *Introduction to Botany*, p. 66,) that in consequence of the extreme inequality in thickness of the annual layers of wood on opposite sides of a stem, a person who judged of the whole age of a tree by the examination of the layers of the stunted side only, would commit errors to the amount of sixty per cent. and more. It is by no means impossible that the great age assigned to the deciduous cypress and the Baobab may be connected with an error of this nature.

In the course of the inquiry into the method of computing the age of ancient trees, a discovery has been made of some importance to timber growers, inasmuch as it shows that those who plant for profit alone should not allow their trees to grow beyond a certain number of years, varying according to species: for it has been found that so far are exogenous trees from continuing always to increase in diameter at the same rate, that every kind diminishes in its rate of growth after a certain age;—the oak, for example, between its fortieth and its sixtieth year, the elm after its fiftieth, the spruce fir after its fortieth, and the yew probably after its sixtieth. With reference to this subject, Professor De Candolle has constructed a table of rate of growth, which we subjoin.

Table of the rate of Increase in Diameter of certain Exogenous Trees, expressed in lines.

Yrs. Yrs.	Quercus pedunculata, 130 years old.	Quercus sessiliflora, 210 years old.	Quercus sessiliflora, 333 years old.	Larch Fir, 255 years old.	Elm, 335 years old.	Spruce Fir, 120 years old.	Yew, 71 years old.
1 to 10	54	10	18	48	16	41	8
10 . 20	64	16	33	61	44	54	11¼
20 . 30	54	22¼	39½	58	58½	52	12

100 . 110	30	9¼	7½	32	30	22	
110 . 120	36	9	8½	26	30	22	
120 . 130	30	9	8	20½	24		
130 . 140		9¼	10	22	24		
140 . 150		10	8	23	18		
150 . 160		8¼	8½	21	19		
160 . 170		9	9	20	17½		
170 . 180		10	8	19	23		
180 . 190		9	8	18	30		
190 . 200		9	7	21	34		
200 . 210		9	8	22	34		
210 . 220			7	22½	26		
220 . 230			6	21	36		
230 . 240			8	22	28		
240 . 250			8	20¼	26		
250 . 260			7½		24		
260 . 270			8		17½		
270 . 280			8		26		
280 . 290			8½		28		
290 . 300			8½		29		
300 . 310			9		16		
310 . 320			8		16½		
320 . 330			8		21		

It is very much to be wished that observations of this kind should be multiplied, as they would probably lead to some very important conclusions, and, at all events, would throw light upon a part of botany that is at present very obscure. It, however, would be of little use to find the diametrical measurement of trees less than 100 years old.

AGES OF THE WORLD. In the mythology of the Greek and Roman poets, the history of the world was divided into four ages, the golden, the silver, the brazen, and the iron; as for instance, Hesiod in his poem entitled *Works and Days*, and by Ovid, in his *Metamorphoses*. The golden age, when Saturn reigned, is represented as having been that of perfect innocence and happiness; from which the others have gradually degenerated more and more,—the iron age, or that which now subsists, being the most wicked and miserable of all. Sometimes these ages are spoken of as merely so many successive periods in the history of Italy. Saturn having been driven out of heaven by his son Jupiter, is supposed to have sought an asylum in that country, where, in return for the protection he received from King Janus, he taught him and his people agriculture, and the other arts of cultivated life. According to this latter mode of telling the story, it will be observed, the golden age is represented as consisting in the triumph of civilization over previous barbarism; whereas the other version seems intended to indicate that the primeval state of man was that in which he enjoyed the greatest felicity and purity, and that he has been rather corrupted than improved by what is called civilization. The two statements, therefore, may be taken as expressing two opposite theories or opinions which have divided speculators upon this subject down even to our own day. The disagreement among the fabulists, however, is only with regard to the original condition of man; it seems to have been admitted on both sides that a gradual declension both of the happiness and virtue of the world has been going on ever since the age of gold. The golden age is that of which the most complete pictures have been drawn; indeed it may be said to be the only one of the four of which the description is at all distinct. The age of iron was deemed to have commenced long before Hesiod's day, who lived probably at least twenty-six hundred years ago; it was, in fact, merely a general name for the existing order of things, as distinguished from some imaginary previous state. But neither that immediately preceding state, designated the age of brass, nor its forerunner, the age of silver, is to be found discriminated in the poetic painting by anything more than some slight varieties of shade. Of the golden age, when universal harmony prevailed throughout the living creation, and the bounteous earth yielded her increase untilled, we have various descriptions from the pens of modern as well as of ancient poets. The reader of Italian poetry will recollect in particular the celebrated chorus at the end of the first act of Tasso's *Aminta*, and the imitation of it at the end of the fourth act of Guarini's *Pastor Fido*.

AGENEIO'SES, in Ichthyology, a genus of abdominal *Malacopterygious* fishes, separated from the silures by Lacepede, and containing two species, both from the fresh-water lakes and rivers of Surinam.

AGENT. An agent is a person authorized by another to do acts, or make engagements in his name; and the person who so authorizes him is called the principal.

An agent cannot be appointed to bind his principal by deed, otherwise than by deed; nor can an agent be appointed by a corporation aggregate (unless it be for certain ordinary and inferior purposes) otherwise than by deed: and for the purpose of making leases and other acts specified in the first, second, and third sections of the statute of frauds, the authority of the agent is required to be in writing. In all other cases no particular form is necessary: in commercial affairs agents are most usually commissioned by a letter of orders, or simply by a retainer; but a verbal appointment is quite sufficient; and even the mere fact of one person's being employed to do any business whatever for another will create between the parties the relation of principal and agent.

An agent's authority (unless it is an authority coupled with an interest, such as a power of attorney granted as a security for a debt) may, in general, be revoked by the principal at any time. It also ceases upon his death or bankruptcy.

There are numberless kinds of agents, answering to the endless diversity of modes in which one person may be employed to act for another. Many of these are known by specific names, such as bailiffs, factors, brokers, &c. The particular rights, duties, and liabilities of each of these will be found under their respective heads. The object of this article is to state the general principles of law, which are applicable equally to all.

Whenever the relation of principal and agent exists between two persons, the law fixes upon them certain rights and duties as the result of such relation; or, (as the same thing is sometimes differently expressed,) the law implies a certain contract between the parties, and points out what shall be the consequences of that contract with respect to third persons.

In the first place, we shall explain what are the rights and duties with respect to one another, resulting from the relation of principal and agent.

And secondly, what are the rights and duties with respect to third persons, resulting from the relation of principal and agent, or, in other words, what is the effect of the contract implied by law between them, as far as regards third persons.

I. First, of the relative rights and duties of principal and agent.

1. The first great duty of an agent is to use faithfully, and in its full extent, the authority which has been given him.

An agent's authority is said to be limited, when he is bound by precise instructions; and unlimited, when he is not so bound. Where his authority is limited, an agent is bound to adhere strictly to his instructions in every particular. Thus, if instructed to sell, he has no right to barter; nor if instructed to sell at a certain price, is he authorized to take less.

When the agent's authority is not limited by precise instructions, his duty is to act in conformity with what may reasonably be presumed to be the intentions of his employer. And in the absence of all other means of ascertaining what these intentions are, he is to act for the interest of his principal, according to the discretion which may be expected from a prudent man in the management of his own business. Thus, if he is authorized to sell, and no price is limited by his instructions, it should be his endeavour to obtain the best price which the goods are fairly worth. If there have been other transactions of the same nature between the parties, it is to be presumed that the principal intends that the same mode of dealing should be pursued, which, in former cases, he had either prescribed or approved of.

In mercantile transactions it is a rule of universal application, that, in the absence of other instructions, the principal must be presumed to intend that his agent should follow the common usage of the particular business in which he is employed. This, therefore, is the course which it is the agent's duty to pursue; and he will, in all cases, be justified in so doing, even though, under the particular circumstances, he might have acted otherwise to the greater advantage of his principal.

Thus a factor of common right is to sell for ready money, but if he is employed in a dealing or trade where the usage is to sell upon credit, he will be authorized in selling to a person of good credit, and giving such time as is reasonable and customary.

An authority is always to be so construed as to include all necessary or usual means of executing it with effect. An agent is, therefore, authorized to do all such subordinate acts as are either requisite by law, in order to the due performance of the principal objects of its instructions, or are necessary to effect it in the best and most convenient manner, or are usually incidental to it in the ordinary course of business.

Thus it is the duty of an agent employed in the receipt or dispatch of goods, to take care that the custom-house duties are satisfied, and the proper entries made; and he will be authorized in making any advances, as well for such incidental charges as warehouse-room, as for any other expense necessarily incurred for the preservation of the property.

2. The next duty of an agent is, in the execution of his trust, to exercise a proper degree of diligence and skill. He is required to use, in the concerns of his employer, the same diligence and care which would be expected from a prudent man in the management of his own business; and he is bound, without any particular instructions, to take every precaution ordinarily used for the safety and improvement of property intrusted to him.

He is also expected, in common with every professional man who holds himself out as ready, for a proportionate remuneration, to transact any particular kind of business for another,—to possess and exercise such a competent degree of skill and knowledge, as may in ordinary cases be adequate to the accomplishment of the service undertaken.

If an agent does an act which is not warranted by his authority, either express or implied, or if he does an act within his authority, but with such gross negligence or unskilfulness that no benefit can accrue from it, the principal may, at his option, either reject or adopt what he has done. But if he rejects it, he must do so decisively from the first, and give his agent notice thereof within reasonable time; for if he tacitly acquiesce in what has been done, and still more if he in any way act upon it, he will be presumed to have adopted it.

Thus, if an agent puts out his employer's money at interest without his authority, or if a factor, employed to purchase, deviates from his instructions in price, quality, or kind; or if he purchases goods which he might at the time have discovered to be unmarketable, the principal may disavow the transaction; but if, in the first cases, he knowingly receives the interest, or, in either of the others, if he deals with the property as his own, he adopts the act of the agent, and takes upon himself all responsibility for the consequences.

But if he does not afterwards either expressly or impliedly adopt the act, the whole hazard of it lies with the agent, even though he did it *bonâ fide*, and for the interest of his employer. Any profit or advantage that may accrue from it he must account for to his principal; and if loss ensues, he is bound to make it good to him. An agent is likewise answerable to his principal for all damage occasioned by his negligence or unskilfulness. This responsibility applies in all cases, not only to the immediate consequences of his misconduct or neglect, but likewise to all such losses, as, but for his previous misconduct or neglect, would not have occurred: such, for instance, as the destruction of goods by fire in a place where he had improperly suffered them to remain; but it does not extend to such losses by fire, robbery, or otherwise, as are purely accidental, and happen by no default of his own; and his responsibility extends to the whole amount of the damage suffered by the principal, either by direct injury occasioned to his own property, or by his being obliged to make reparation to others.

If an agent's negligence is so gross, or his deviation from his authority so great, as to amount to a breach of the duty created in law, by the relation of principal and agent, or (which is the same thing) to a breach of the contract, which (if none exist) the law, as we have before seen, will imply between them, the agent is liable to an action for such breach of duty or of contract, whether any injury has been sustained by it or not; but if no injury has been in fact sustained, the damages will be merely nominal.

3. The third general duty of an agent is to keep a clear and regular account of his dealings on behalf of his principal, including as well what he has received as what he has paid; to communicate the results from time to time; and to account when called upon, without suppression, concealment, or overcharge.

An agent is not in general accountable for money until he has actually received it, unless he has, by improper credit, or by other misconduct or neglect, occasioned a delay of payment. But an agent acting under a commission *Del credere*, that is, one who has undertaken to be surety to his principal for the solvency of the persons he deals with, is, in their default, accountable for the debt; and in all cases where an agent has actually received money on behalf of his principal, he is bound to take care of it according to the general rules which regulate his conduct; and if any loss is occasioned by the fraud or failure of third persons, he will, unless his conduct be warranted by his instructions, or the usage of trade, be bound to make it good; if a stranger, for instance, calls upon him by a written authority to transfer the money in his hands, and the authority is a forgery, he will remain accountable for all that is transferred under it.

The principal is in general entitled not only to the bare amount of what has been received by his agent, but to all the increase which has accrued to the property while in his possession. The agent is, therefore, accountable for the interest, if any has actually been made, upon the balance in his hands; and likewise for every sort of profit or advantage which he may have clandestinely derived by dealing or speculating with the effects of his principal.

4. It is also the duty of an agent to apprize his principal, with all convenient expedition, of all material acts done or contracts concluded by him.

5. An agent, confidentially intrusted and relied on for counsel and direction—as an attorney, for instance—is rarely allowed, in equity, to take a gift from his employer; especially if it is a grant of the property which he has been employed to manage; and it is also a general principle, that an agent cannot make himself an adverse party to his principal —if he is employed to sell, he cannot make himself the purchaser: such a transaction is liable to be set aside in a court of equity, unless it be made clearly to appear that the principal gave his express consent to it, and that the agent furnished him with all the knowledge he himself possessed: and in like manner, an agent employed to purchase cannot be himself the seller; if he acts as such, he is accountable to his principal for all the profits he has made by his indirect dealing.

We are now to consider what are the obligations of the principal with respect to his agent; in other words, what are the rights of an agent.

1. The first right of an agent is to his commission; that is, the remuneration to be paid to him in return for his services. The amount of commission is sometimes determined by positive agreement between the parties; sometimes it is regulated by the usage of trade; and in some few cases, as of brokerage for the procuring of loans, &c., the amount of commission is limited by act of parliament.

An agent has no right to commission for doing any act not within his authority, unless it is afterwards adopted by his principal. He may also forfeit his right to commission by misconduct: as, if he keeps no account; if he makes himself an adverse party to his principal; or if, in consequence of his negligence or unskilfulness, no benefit accrues to the principal from the services performed.

2. Besides his commission, an agent is entitled to be reimbursed all such advances made on behalf of his principal, as are justified by his authority, whether express or implied, or subsequently sanctioned by his principal. And cases may sometimes occur of urgent danger, without means of ref

ring for instructions, in which an agent, acting for the best, is justified in making advances without particular directions, and under exigencies not provided for by regular rules of business. Thus if, on account of the lateness of the season, or other good cause, he insures the cargo without orders, he is entitled to charge his principal with the premium, and in such a case even the assent of the principal would be inferred from very slight circumstances. But an agent is not entitled to be reimbursed payments that are merely voluntary and officious; nor expenses occasioned by his own negligence or unskilfulness.

An agent has also, as a further security, a LIEN upon the property of his principal; that is, a right to retain it in his possession in the nature of a pledge for the satisfaction of his demands. Lien is either particular or general. A particular lien is a right to retain the thing itself in respect of which the claim arises. This right is very extensively admitted in our law, and is possessed by bailees in general, and consequently by all agents in the nature of bailees. [See LIEN.]

General lien is a right to retain any property of the principal which may come into the agent's possession in the regular course of business. This, being an extension of the general right, exists only where it is created by express contract, the previous dealings of the parties, or the usage of trade. Factors, packers, where they are in the nature of factors, insurance-brokers, and bankers, have, by usage, a general lien in their respective employments.

This right may in general be exercised in respect of any claim to commission or reimbursement, which the agent may have acquired in the due execution of his authority; but it does not extend to demands arising from transactions not within his course of dealing as such agent. An agent can, therefore, have no lien for debts due to him as agent for a third person, nor, as it should seem, for any demands which originated before the commencement of his agency.

An agent's lien does not attach unless the property is actually in his possession: a consignee has, therefore, no lien on goods consigned to him, if the consignor stops them before they come into his hands: nor unless it has come into his possession in the ordinary course of business; he has consequently no lien on property which has been casually left in his office, which has been deposited with him as a pledge for a specific sum, or which he has obtained possession of by fraud or misrepresentation. And if an agent parts with the possession of the property, the lien, being a personal right, is in general lost: but by stat. 6 Geo. IV. c. 83. (the factor's act,) if a factor pledges the goods or commercial documents of his principal as a security for advances made, with notice that they are not his own; or if, without such notice, he pledges them for a pre-existing debt due from himself, the lien of the factor on such goods or documents is transferred to the person with whom they are pledged; that is to say, in other words, he acquires the same right upon them which the factor, while they remained in his possession, could have enforced against the principal.

The right of lien may also be destroyed by the special agreement of the parties; and if the agent enters into a contract with his employer inconsistent with the exercise of the right, (as if he stipulates for a particular mode of payment,) he must be understood to waive it.

We have hitherto considered only the case of hired or paid agents; between whom and gratuitous agents there exists nearly the same difference with respect to their relative rights and duties as between bailees for hire and gratuitous bailees. [See Sir W. Jones, *On the Law of Bailments*.]

The responsibility of a gratuitous agent (the mandatary of the Roman law) is much less than that of one who is paid for his services. He will in general incur no liability, provided he acts with good faith, and exercises the same care in the business of his employer as he would in his own. But if he is guilty of gross negligence, or if, having competent skill, he fails to exert it, he will be answerable to his employer for the consequences. He has of course no right to commission, but he is entitled to be reimbursed for any reasonable payments made, or charges incurred in behalf of his employer. [For the principles of the civil law as to the rights and obligations of principal and agent, see Domat's *Civil Law*, book 1, tit. xv.]

II. Having considered what are the legal consequences of the relation of principal and agent, as far as regards the parties themselves, it now remains to explain the consequences of this relation as between the parties and third persons; and, first, as between the principal and third persons; and, secondly, as between the agents and third persons.

First, then, as between the principal and third persons: it is a general rule that the act of the agent is to be considered as the act of the principal; giving him the same rights, imposing on him the same obligations, and subjecting him to the same liabilities as if he had done it in his own proper person.

A bargain or agreement entered into by an agent is therefore binding upon his principal, whether it tends to his benefit or his disadvantage; and, in order to have this effect, it is not absolutely necessary that it should actually be within the agent's real authority, either express or implied, provided it be within what may most properly be called his *apparent authority*,—that is, provided it is such as the person dealing with the agent might, from the conduct of the principal, reasonably presume to be within his authority.

An authority may be presumed, first, from the principal's having previously authorized or sanctioned dealings of the same nature. Thus, if a person has been in the habit of employing another to do any act,—as, for instance, to draw or indorse bills,—he will be answerable for any subsequent acts of the same nature,—at least, until it is known, or may reasonably be presumed, that the authority which he had given has ceased. An authority may likewise be presumed from the conduct of the principal, with reference to the subject-matter of the transaction in question. For if a person authorizes another to assume the apparent right of engaging in any transactions, the apparent authority must, as far as regards the rights of third persons, be considered as the real authority. Thus, a broker employed to purchase has no authority to sell; and if he does, his employer may (unless the sale was in market overt) reclaim the goods so sold, into whatever hands they may have come. But if the principal has permitted the broker to assume the apparent right of selling the goods, he will be bound by a sale so apparently authorized.

Upon the same principle, where a general agent is employed,—that is, an agent authorized to transact all his employer's business of a particular kind, as to buy and sell certain wares, or to negotiate certain contracts,—he must be presumed to have all the authority usually exercised by agents of the same kind in the ordinary course of their employment: and though the principal may have limited his real authority by express instructions, yet he will not thereby be discharged from obligation incurred in the ordinary course of trade, towards persons who have dealt with the agent without any knowledge of such limitation. Thus where an agent purchases goods on credit, the seller may come on the principal for payment: and this right cannot be affected by any private agreement between the principal and agent, by which the agent may have stipulated to be liable to the seller.

Although the agent is, in all these cases, ultimately answerable to his employer for any damage that may follow from his having entered into an engagement not within his authority; yet the principal is, in the first instance, bound to keep an engagement so entered into by his agent upon a reasonable presumption of authority.

But in the case of a special agent (that is, of a person appointed merely to do certain particular acts), as no presumption of authority can arise from usage of trade, so the principal will not be bound by any act, not within the real authority of the agent,—and it lies upon those who deal with the agent to ascertain what that authority actually is.

Thus, in order to illustrate more fully the difference in this respect between general and special agents,—If a person employs a stable-keeper, whose general business it is to sell horses, to sell a particular horse for him; and he warrants the horse to be sound, inasmuch as the giving such warranty is within the ordinary course of his employment, the owner will be bound by such warranty, even though he may have directed expressly that none should be given; but if he employs another person to sell his horse, whose ordinary business it is not to sell horses,—then, although, if he has given no orders to the contrary, the agent will be justified in giving a warranty, as being a thing incidental to the main object of his employment; yet if he has given express orders that no warranty should be given, and the agent gives a warranty in opposition to his orders, he will not be bound by it.

As the agreement made by an agent, so likewise all his dealings in connexion with it, provided they are within his real or apparent authority, are as binding on the principal, as if they were his own acts.

Thus the representations made by an agent, at the time of entering into an agreement, (if they constitute a part of such agreement, or are in any way the foundation of, or inducement to it,) and, in many cases, even the admissions of an agent as to anything directly within the course of his employment, will have the same effect, as if such representations or admissions had been made by the principal himself. [See EVIDENCE.]

So also if notice of any fact is given, or if goods are delivered to an agent, it will be considered as notice or delivery to the principal. And in general, payment to an agent has the same effect as if it had been made to the principal, and in such cases the receipt of the agent is the receipt of the principal. But such payment is not valid if it is not warranted at law by the apparent authority of his agent.

Thus, if money is due on a written security, as long as the security remains in the hands of an agent, it is to be presumed that he is authorized to receive the money, and payment to him will therefore discharge the debt: but if the agent has not the security in his possession, the debtor pays him at his own risk, and will be liable, in case the agent should not account for it to his principal, to pay it over again.

So also if the principal gives notice to the buyer not to pay the money to the factor with whom he made the bargain, he will in general not be justified in doing so; but if the factor had a lien upon the goods for his general balance, then, inasmuch as his lien will attach upon the price of the goods when they are sold, he has a right to require the buyer to pay him instead of his principal: and such payment to the factor, notwithstanding any notice given by the principal, will operate as a discharge of the debt.

A principal is in general civilly liable for all damage occasioned to third persons by the negligence or unskilfulness of his agent within the scope of his employment; and for any misconduct or fraud committed by him, if it be either at his express command or within the limits of his implied authority.

From this liability, however, it is reasonable that those persons should be exempted, who, though they appear in some degree in the character of principals, yet have no power in the appointment of those who act under them. Thus the post masters-general, and persons at the head of other public offices, have been held not to be liable for the conduct of their inferior officers.

And, on the same principle, the owners and masters of vessels are by statute released from all liability to third persons from the negligence or unskilfulness of the pilots by whom they are navigated into port.

It now remains for us to state what are the effects of the relation of principal and agent, as between the agent and third persons.

An agent is not in general personally responsible on any contract entered into by him on behalf of his principal: to this rule, however, there are several exceptions.

First. If an agent has so far exceeded his authority that his principal is not bound by his act; as for instance, if an agent without any authority undertakes for his principal to pay a certain sum, or if a special agent warrants goods, contrary to his instructions; and the principal refuses to adopt such undertaking or warranty, the agent alone is liable to the person to whom it was given.

Secondly, an agent is liable where the contract was made with him individually. And, therefore, if in any contract made on behalf of his principal, the agent binds himself by his own express undertaking; or if the circumstances of the transaction are such that the credit was originally given to him and not to the principal, (whether such principal were known at the time or not,) in either of these cases he will be liable, in the first instance, to the persons with whom he has so dealt.

And for the same reason, when an agent takes upon himself to act in his own name, and gives no notice of his being employed in behalf of another person—as if a factor delivers goods as his own and conceals his principal—he is to be taken, to all intents, as the principal, and the persons who have dealt with him are entitled to all the same rights against him as if he actually were so. They may, for instance, in an action by the principal on demand arising from such transactions, set off a debt due from the agent himself; which they could not have done, if they had known that he acted only as an agent. And if he afterwards discloses his principal, he is, nevertheless, not discharged from his liability,—those with whom he has dealt may, at their option, come either upon him on his personal contract, or on the principal upon the contract of his agent.

And even where it is known, that the agent acts in a representative character, yet if the principal is not known, or if there is no responsible principal to resort to,—as may be the case with the committee of a club, or the commissioners appointed under a navigation act,—the agent will be personally liable on all the contracts he enters into.

An agent is likewise responsible to third persons for any wrongful acts, whether done by the authority of his principal or not;—and in most instances the person injured may seek compensation either from the principal or the agent, at his option.

An agent cannot delegate to another the authority which he has received, so as to create between his employer and that other person the relation of principal and agent: but he may employ other persons under him to perform his engagements, and the original agent is responsible to his principal as well for the conduct of such sub-agents, as for his own: but with respect to damage sustained by third persons from the wrongful acts of such sub-agents, the case is different; such damages must be recovered either from the person who in fact did the injury, or from the principal for whom the act was done. The original agent is responsible to third persons only for his own acts, and such as are done at his command.

The misconduct of an agent, besides the civil responsibility which it imposes on him, amounts in some cases to a misdemeanor, subject to very severe punishment. For if an agent intrusted with any money or valuable security, with written directions to apply the same in any particular manner, in violation of good faith converts it to his own use; —or if an agent intrusted with any chattel, valuable security, or power of attorney for the transfer of stock, either for safe custody, or for any special purpose, in violation of good faith, and without authority, sells or pledges, or in any manner converts the same to his own use, he is in either case guilty of a misdemeanor punishable with fourteen years' transportation. [See EMBEZZLEMENT.] But this does not extend to prevent his disposing of so much of any securities or effects on which he has a lien or demand, as may be requisite for the satisfaction thereof. It is also a misdemeanor, punishable in the same manner, if a factor or agent employed to sell, and intrusted with the goods or the documents relating to them, pledges either the one or the other, as a security for any money borrowed or intended to be borrowed, provided such sum of money is greater than the amount which was at the time due to the agent from the principal, together with any acceptances of the agent on behalf of his principal. Stat. 7 and 8 Geo. IV., cap. 29, sect. 49, &c.

AGESILA'US, younger son of Archidamus, king of Lacedæmon, succeeded his brother Agis, B.C. 398, to the exclusion of his nephew Leotychides, who laboured under the stigma of bastardy, being believed to be the son of Alcibiades, and not of Agis, his reputed father. As the crown descended in direct line from father to son, the succession of Agesilaus seemed, in his youth, to be barred; and his education was conducted as that of a private person, in all the strictness of Spartan discipline. He was lame, and advantage was taken of this to excite a prejudice against him: yet so high was his personal character, or so general the belief in the spurious birth of Leotychides, that by a vote of the general assembly, the heir-apparent was passed over, and Agesilaus was appointed king.

In the first year of his reign, a plot was formed to effect a change of government. The political constitution, established by Lycurgus, had degenerated into an oligarchy of a peculiar kind. Almost all political power, with the exclusive right to hold high civil or military office, was engrossed by those families who boasted to be of pure Spartan blood, the term *Spartan* being opposed to *Lacedæmonian*. This Spartan caste is supposed to have consisted of the legitimate and unmixed descendants of the original Dorian conquerors: the Lacedæmonians are conjectured to have been the progeny of enfranchised Helots, strangers associated into the citizenship, a remnant of the Achæi, and in a word, all who could not trace an unblemished line of Spartan descent to the early ages of the monarchy. Foreigners might become members of the community and Lacedæmonians: but they could never become Spartans; at least, Herodotus only knew of two instances up to his time (ix. 33, 35). The consequence was, that the bulk of the population became constantly more Lacedæmonian; in the time of Agesilaus, the number of Spartans had so dwindled, that they could not be spared for foreign service in any rank below that of commanders. The ephori, and all the leading officers of administration, civil and military, were taken from this privileged caste. The object of Cinadon's conspiracy, who complained that he counted only forty Spartans in the *agora*, or place of assembly, and that these were all official persons, was to extend the right of holding these high offices to all citizens. As happens in a majority of cases, the plot was discovered before it was ripe; Cinadon, the author and ring-leader, was executed, and the Spartans held fast their monopoly.

In order to prosecute more effectually the war with Persia (B.C. 396), Agesilaus was sent to command in Asia. At setting out, he pledged himself either to conclude an honourable peace, or to press his enemies so as to disable them from giving any further disturbance to the Greeks. His first object was to conciliate the Asiatic cities by prudent management and liberality; and he succeeded in reconciling their factions. It may be doubted whether the design of Agesilaus was limited to the protection of the Greek states of Asia. The recent example of the successful retreat of the *ten thousand* (see ANABASIS), the powers with which Agesilaus was invested, and the disorganized state of the Persian monarchy, would perhaps have tempted him to penetrate as far as Susa and Ecbatana, had he been allowed to follow up his successes. But the war that broke out in Greece, after he had been about two years in Asia, saved the Persian monarchy for a time, and reserved the triumph of its overthrow to the Macedonians and Alexander.

The intrigues of the Persians and the hatred of the Spartan influence had occasioned a dangerous league to be formed against Sparta; nor were the Spartans sorry to have an opportunity for going to war, especially against the Thebans, whom they detested for various causes (Xenophon *Hellenic.* iii. 5). Thebes, Argos, and Corinth declared against the Lacedæmonians, and Athens followed the example at the pressing instance of the Thebans. The ephori ordered Agesilaus home: in the height of his glory, and with the prospect of victory, he instantly obeyed. The Lacedæmonians and their enemies met near Coroneia in Bœotia, and a fierce battle took place (August, B. C. 394). The Thebans alone made a gallant resistance; and the Spartan king was wounded, who obtained only a doubtful victory. He returned to Sparta, not importing with him the luxuries of Asia, but adhering to the temperance and frugality characteristic of his country's discipline. Those virtues were peculiarly Spartan: and that nation was not exempt from the meanness of jealousy. The probability of Athens recovering her former power after her walls were rebuilt (B.C. 392), induced the Spartans to send Antalcidas (B.C. 387) with proposals to Persia, favourable to themselves, but disadvantageous to the rest of Greece. The bearer of these offers was the personal enemy of Agesilaus, and was supposed to have a mean pleasure in lessening his power and tarnishing his glory. The Persians dictated the treaty in the language of conquerors (Xen. *Hellen.* V., i. 31). All the Grecian cities of Asia were to be subject to the king of Persia: all the rest to be independent: the king was to keep possession of Cyprus and Clazomenæ; and the islands Lemnos, Imbros, and Scyros, were given to the Athenians, to whom they formerly belonged. Artaxerxes concluded with denouncing war against those who should not submit to his terms. The Thebans refused; but their steadiness was shaken by preparations for coercion on the part of the ephori, invidiously recommended by Agesilaus, in revenge for a former affront. Thus the bad policy of the Greeks, arising from their foolish dissensions, annihilated the advantages which should have been the fruit of victories and military virtue of no common stamp. Sparta had now, though not worthily, recovered her power in Greece. Her virtues, indeed, were to be found rather in adversity than prosperity; nor did she profit by her own experience, that tyranny leads to the destruction of the tyrant. Phæbidas, one of her generals, on his march into Thrace against Olynthus, was encamped in the neighbourhood of Thebes, while parties were so nearly balanced, that Ismenias and Leontiades, the heads of opposite factions, exercised the chief magistracy together. Leontiades, who *courted* the friendship of Lacedæmon, secretly introduced Phæbidas and his troops into the Cadmeia, the citadel of Thebes (B. C. 382). This at once gave the superiority to that party of which he was the head: Ismenias was apprehended, and 400 of his friends immediately fled to Athens. Complaint was made at Sparta of this treacherous aggression in time of peace. Agesilaus was, in general, more just and liberal than the rest of his countrymen; but he contended that it was necessary to examine whether the possession of the Cadmeia was of advantage to Sparta, to which every other consideration must give way: and in this instance, he not only discredited, but contradicted his better thoughts. On a former occasion, speaking of the king of Persia, he said, 'Can this king, whom you call Great, be more so than I, if he be not more just?': this anecdote rests on Plutarch's authority. The decree of the Spartans was, as we might expect, in their own favour. The assembly resolved to keep the citadel, and to bring Ismenias to trial, who had been seized and imprisoned by his opponent, ostensibly on the vague charge of seeking Persian connexions, but really for the vote which he had carried, forbidding any Theban to join the army of Phœbidas. But a counter-revolution was soon effected; and the Spartans were compelled to evacuate the citadel.

That the Lacedæmonians, when now at the height of power, were all at once involved in a train of misfortunes which effectually broke that power, is ascribed by Xenophon to the divine anger against their perfidious seizure of Thebes. Agesilaus probably had come round to the same opinion; for he excused himself from the command of the army sent to reduce the Theban revolutionists, on the plea of being weighed down by age. His colleague, Cleombrotus, was appointed in his stead. The events which occurred during the absence of Agesilaus, form no part of the present subject. On returning home, Cleombrotus left Sphodrias at Thespiæ, in command of part of his army. Sphodrias, whether from his own folly, or, as many believed, induced by Pelopidas, made a most unwarrantable and faithless inroad upon Attica. The Athenians complained to Sparta, and Sphodrias was recalled, and brought to trial. Unfortunately, Agesilaus was persuaded to exert his influence in the delinquent's favour and he was acquitted; at which the Athenians were so much offended, that they immediately concluded an alliance with Thebes against Sparta. Agesilaus then resumed the command, and held it through two successive campaigns, till obliged to resign through failing health.

The battle of Leuctra, (B.C. 371,) in which the Lacedæmonians under Cleombrotus were overcome by inferior numbers, produced a striking instance of Spartan character. The news arrived at Sparta during a religious festival, but the ephori did not allow the celebration of it to be interrupted. The list of the slain was sent to the houses of their kindred, and the women were told to bear their sorrows in silence. Those parents whose children had met with a glorious death went abroad the next day to receive congratulations; the friends of the survivors kept their houses, as if in shame and sorrow. On this occasion, a number of the combatants having fled, Agesilaus was allowed to suspend the law, which visited cowardice with disgraceful punishment. He prudently announced that it might sleep for one day only, and then resume its power.

There was a proverb, frequently repeated by Agesilaus, 'That a Spartan woman had never seen the smoke of an enemy's camp:' but he had the mortification to see his proverb belied. The Theban army increased daily by the defection of the allies of Sparta: it penetrated into Laconia, and laid waste the whole country; the city, however, was saved by the prudence of Agesilaus, who shut himself up in Sparta, and avoided an engagement. Epaminondas did not venture to assault the city; and at last, his allies growing weary of the service, the winter approaching, and relief coming to Sparta from Athens, the Theban general found it necessary to retreat.

After the death of Epaminondas, at the battle of Mantinæa, (B.C. 362,) the weariness of all parties produced a partial cessation of hostilities. Agesilaus was now above eighty years old, but he had still vigour enough left to lead an army into Egypt, to assist the Egyptians who had rebelled against the Persian king. According to Plutarch, Agesilaus went expressly to help Tachos against his master King Artaxerxes II.; but a rival to Tachos starting up in the person of Nectanebos, another Egyptian, Agesilaus found it convenient to change sides. That his motives were not of the purest kind, may very safely be asserted. After establishing Nectanebos in the government of Egypt, the old king set out on his voyage homewards, loaded with money and presents, the reward of his services and his treachery. Being driven by contrary winds on the coast of Africa, he died there at the advanced age of eighty-four. His attendants preserved the body in melted wax, and took it to Sparta to be buried, consistently with the usages of their country, which did not allow the body of a king to rest in a foreign land.

The character of Agesilaus is exalted by Xenophon far above its merits. The historian was on terms of personal intimacy with the Spartan king, and was besides no great admirer of the constitutional forms of Athens, his native city, which he loved to contrast disadvantageously with those of Sparta. We may admire the energy and vigour of Agesilaus, and grant him a full share of those peculiar virtues, as they are termed, which characterized his country. He may also have been temperate in his habits, kind to his friends, and not cruel to his enemies; but more than one public act of his life is of such a description as to throw suspicion on his integrity as an individual and a statesman. (See Plutarch's *Life of Agesilaus;* Xenophon's *Hellenica,* and *Panegyric on Agesilaus;* Pausanias, iii. 9.)

AGGERHUUS, a name of one of the five great divisions of the kingdom of Norway, better known under that of CHRISTIANIA.

AGGERZEEN, the name of a species of large antelope, mentioned by Pearce, in his *Account of his Residence in Abyssinia.* Unfortunately he gives no account of its form, nor description of its characters, and the only information which he affords of its habits is, that it occasionally mixes with the herds of domestic cattle which graze in the vicinity of the forests, and that the natives esteem its flesh for making brind, that is, meat cut into long slices of the breadth and thickness of a man's hand, and dried in the sun. This meagre account is insufficient to enable us to identify the species; but if, as we suppose, the aggerzeen of Pearce be the same animal which Salt mentions in the *Appendix to his Second Journey,* under the name of agayen, it would appear, according to the report of that traveller, to be the koedoe of the Cape, the antelope *Strepsiceros* of naturalists; a species which inhabits moist, woody situations, and to which the physical characters of the low parts of Abyssinia are in all respects well adapted. We have not been able to find the name in Lobo, Poncet, Bruce, or any other traveller. (See ANTELOPE, *Strepsiceros.*)

AGHRIM, a village in the county of Galway, in Ireland, famous for the great victory obtained in its neighbourhood, on the 12th of July, 1691, by the forces of King William, commanded by General Ginkell, over those of King James, commanded by General St. Ruth. The latter were 25,000 strong, and very advantageously posted; the former amounted only to 18,000, and had to march to the attack through a bog, in which they sunk up to the middle. The result was in a great measure owing to the circumstance of General St. Ruth being killed by a cannon ball in the early part of the action; and the officer who took the command having, through a jealousy which subsisted between them, been left in ignorance of the dispositions of his superiors. The attack of the English, however, was singularly bold in conception, and the impetuosity with which it was commenced was sustained in a manner which has probably never been surpassed. The victors, not satisfied with gaining the battle, followed up their success with a terrible slaughter of the defeated and flying enemy, whom they pursued till night-fall: no fewer than 7000 are said to have been destroyed. Only 450 prisoners were taken. The loss of the English did not exceed 700 killed, and 1000 wounded. All the enemy's baggage and ammunition fell into their hands; and the victory was followed by the immediate and complete submission of Ireland. The accounts of this battle mention an old castle of Aghrim, which was occupied by a party of the Irish infantry. In Archdall's *Monasticon Hibernicum* it is stated, that there was formerly here a priory of canons regular of St. Augustine, which was said to have been founded in the 13th century. Aghrim, which is a vicarage, in the diocess of Clonfert, had, in 1806, a church in good repair, with a glebe house, and above twenty acres of glebe. [See Carlisle's *Topographical Dictionary of Ireland,* 1814.] It is in the barony of Clonmacow, and is situated twenty-eight miles east from the town of Galway, and seventy-five miles west from Dublin. The village is now much decayed. There is another Aghrim in Wicklow, (sometimes mistaken for that at which the battle took place,) which is a market-town, situated on the banks of the Ovoca, or Avoca, thirty-five miles from Dublin. There is also a village named Aughrim in the county of Roscommon.

AGINCOURT, or AZINCOUR, a village in the department of Pas de Calais, France, in the ancient province of Artois, celebrated for a great victory obtained by the English under Henry V., over a French army vastly superior in numbers. Encouraged by the distracted condition of France, where the imbecility of Charles VI. had allowed the quarrels of the nobility to reach a great height, prompted by his own ambition, and perhaps desirous of finding employment for the turbulent spirits of his own court, the English monarch, in 1415, conveyed over to Normandy (the hereditary possession at one time of his ancestors) a considerable army, and having reduced the town of Harfleur near Havre, set out for Calais. The siege of Harfleur occupied thirty-six days; and the loss sustained by the English, principally by sickness, during this period, was immense. Upon reaching Abbeville and Amiens, Henry found the passes of the Somme guarded, and the bridges broken down; but, having erected a temporary bridge, at a place called Nesle, he passed his army over, and, pursuing his route, came to an engagement with his opponents on the 25th of October in the year abovementioned. The disparity of forces was very great: the English army, at the commencement of the invasion, consisted of about 2500 men at arms, 4000 archers on foot and as many on horseback, and other troops to the number of 1000; but the attendants of the men at arms and other followers swelled the whole to about 30,000. The loss during the siege, the garrison left to defend the conquest, the ravages of disease (the dysentery), and the desertion of several, reduced this force exceedingly. An ancient muster-roll, still extant, gives 812 as the number of men at arms who were with the king at Agincourt, and 3071 archers; so that, allowing two attendants to each man at arms, we have a total of rather more than 5500. No ancient English writers make the number more than 10,000; and two French writers, one of whom was with the English army, say it was about 11,000 or 12,000. Other French writers make it 15,000, 18,000, or even 20,000. The accounts of the number on the other side differ as widely, varying from 50,000 to 150,000.

The previous night was passed by the English near the village of Maisoncelles, in preparing their weapons, confessing themselves, and receiving the sacrament; by the French, who were posted a mile off, between Ruissauville and Agincourt, in gaming and drinking. The descriptions of Shakspeare, in which these circumstances are mentioned, are supported by the contemporary chroniclers. In the morning the armies were formed. The English archers were posted in front, supported by the main body under the king in person, and flanked by the wings under the Duke of York and Lord Camoys respectively. The baggage had been left under a guard near Maisoncelles, and with it several priests on horseback, who put up their prayers for the success of their countrymen. The archers, to whom the victory was mainly owing, wore little armour, but, in addition to their bows, they had hatchets or swords hanging from their girdle; many were barefooted and had no hats, while others had leather caps crossed with iron. Henry had, during the march, ordered them to provide themselves with long stakes, which they might plant before them to resist the charge of cavalry.

The French were drawn up in three lines; the first under D'Albret, Constable of France (who commanded in chief), accompanied by many noblemen; the second under the Duke of Alençon, the Duke of Bar, and others; and the third under Counts Marle, Dampmartin, &c. The ground, being between two woods, was too narrow for them to avail themselves usefully of their superior numbers; and a heavy rain which had fallen the night before, and the trampling of the horses, who were kept moving all night by the pages, had broken it up.

Henry, who had heard mass in the morning, addressed his little army; and after an unavailing negotiation (commenced by the French), Sir Thomas Erpingham, who had drawn up the archers, threw up his truncheon, and gave the signal for the attack. The volleys of arrows did fearful execution among the French, while the stakes of the archers enabled them to repel the attack of some cavalry on their flanks. They gave way, indeed, for a minute, to the charge of the French line under the Constable, but, rallying, they cast aside their bows, and made havoc with bill-hooks and hatchets. The French pressed on over the dead until they were piled up almost to the height of a man, and then the English mounted on the heaps, and slaughtered their enemies, whose heavy armour and crowded array rendered them almost incapable of resistance. The first and second lines of the French were routed, notwithstanding a brave attempt of the Duke of Alençon to rally his forces. That nobleman exchanged blows with the king himself, and was slain, as were a vast number of knights and noblemen. The third line fled, with the exception of their leaders and a few others, who were either killed or taken; and, after a contest of three hours, the victory remained with the English. During the battle the baggage of the victors was plundered by some peasants and a few men at arms; and upon a report of this, and of the rallying of the French rear, Henry ordered the prisoners taken to be slain. This cruel order was, except with respect to a few men of rank, complied with.

The loss of the respective armies is variously stated: that of the French was probably 10,000, including the Constable, three Dukes, five Counts, and ninety Barons. The victors lost probably 1200, including the Duke of York, the Earl of Suffolk, and one or two other persons of rank. Henry continued his march to Calais, which he reached on the 29th, and from thence proceeded to Dover and London, which last he entered, with great pomp, on the 23rd of November. The immediate consequences of the battle were by no means important. It was a useless display of valour, prompted by personal ambition. Upon such fearful scenes of carnage mankind will, one day, look with astonishment and shame, instead of admiration. [See Nicolas's *History of the Battle of Agincourt*, 1827.]

AGIO, a term generally used to denote the per centage difference existing between the values of the current and standard monies of any place. The metallic currency of wealthy states generally consists of its own coin exclusively, and it is in the power of the state to prevent the degradation of that coin below the standard, so that no calculations of agio, strictly so called, are rendered necessary. In smaller states, the currency seldom entirely consists of their own coin, but is made up of the clipt, worn, [and diminished coins of the neighbouring countries with which the inhabitants have dealings. Under these circumstances, banks were, at different times, established by the governments of Venice, Hamburg, Genoa, Amsterdam, &c., which, under the guarantee of the state, should be at all times bound to receive deposits and to make payments, according to some standard value. The money, or obligations of these banks being better than the fluctuating and deteriorated currency of the country, bears a premium equivalent to the deterioration, and this premium is called the agio of the bank.

To facilitate his money dealings, every merchant trading in a place where the deterioration of the currency is thus remedied, must have an account with the bank for the purpose of paying the drafts of his foreign correspondents, which drafts are always stipulated to be paid in bank or standard money. The practice being thus universal, the commercial money payments of the place are usually managed without the employment of coin, by a simple transfer in the books of the bank from the account of one merchant to that of another. The practical convenience, which this plan of making their payments affords to merchants, who would otherwise be obliged, when discharging obligations incurred in standard money, to undergo troublesome and expensive examinations of the various coins in use, causes the money of the bank to bear a small premium above its intrinsic superiority over the money in circulation, so that the agio of the bank does not usually form an exact measure of that superiority.

The term agio is also used to signify the rate of premium which is given, when a person having a claim which he can legally demand in only one metal, elects to be paid in another. Thus in France, silver is the only legal standard, and payments can be demanded only in silver coin, a circumstance which is found to be so practically inconvenient, that the receiver will frequently pay a small premium in order to obtain gold coin, which is more easily transportable; this premium is called the agio on gold.

AGIS. Four kings of Sparta have borne this name. The first was the son of Eurysthenes, and grandson of Aristodemus, to whom Laconica was allotted after the Heracleid invasion. Aristodemus had two sons, Eurysthenes and *Procles*; and this Agis was, therefore, the second in one of the series of that double race of kings, which reigned conjointly. No certain dates can be assigned to these early times. The other kings bearing this name were of the race of the Proclidæ. (See Pausanias, iii. 2.)

AGIS II. the son of Archidamus, reigned from B.C. 427 or 426 to 397, and was actively engaged in the Peloponnesian war. In the fourteenth year of the Peloponnesian war, the Lacedæmonians endeavoured to recover their influence in Peloponnesus, and marched out with all their force under Agis. His generalship was so skilful, that the Argeian army, against which his operations were directed, was completely hemmed in, and exposed to great danger. Two Argeians went privately to Agis, and pledged themselves to effect a reconciliation between their country and Lacedæmon, if he would grant a truce of four months. To this he consented on his own authority. The order to retreat was heard with astonishment by the army of Agis, and the Argeians, on their part, were highly incensed against their countrymen for having defrauded them of an opportunity, as they thought, of destroying the enemy. The Lacedæmonians were loud in their displeasure against Agis for his retreat. He was called to account, and it was proposed to fine him, and demolish his house; but his humble demeanour and earnest entreaty prevailed, and he was allowed to resume the command, under the mortifying restriction of a superintending council. But he made amends, a short time after, by defeating the Argeians, and their allies the Athenians, in a great battle. [Thucydides, v.—Pausanias, iii. 8.]

In B.C. 421, the Eleians had been involved in a dispute with Sparta, which afterwards led to their taking a part in the war just alluded to, as allies of the Argeians. Agis conducted an army into Elis, which yielded him abundant spoil, since it had usually been accounted sacred ground, as the scene of the Olympic festival, and therefore exempted from the ravages of war. The resort of strangers to the games also brought a great accession of wealth. The city of Elis, as neutral ground, was unfortified; and Xenophon says, that Agis was supposed rather to be unwilling than unable to capture it. At the siege and surrender of Athens, accompanied with the mortifying demolition of the long walls, and the fortifications of Peiræeus, Pausanias and Agis, the two kings of Sparta, with the whole strength of the Peloponnesian allies, conducted the operations by land, while Lysander blockaded the city with his fleet. Agis was succeeded by his brother Agesilaus. [See AGESILAUS.]

AGIS III., the son of another Archidamus, reigned from B.C. 338 to 331 or 330. At the time of the battle of Issus, (B.C. 333,) Agis was communicating with the Persian naval commanders in the Ægean, to obtain supplies for the war against the Macedonians. While Alexander was engaged in his fourth campaign in Asia, (B.C. 331,) an action between Agis and Antipater, whom Alexander had left governor of Macedonia, took place in Peloponnesus. Authorities differ as to the precise date of the battle: Plutarch ascribes it to the year here mentioned; Diodorus places it one year later. The Lacedæmonians had formed the siege of Megalopolis, which however held out till the arrival of Antipater to its relief. A bloody battle was fought, in which the Lacedæmonians behaved with their accustomed gallantry, but were overpowered by superior numbers. Agis, their king, fell after this phalanx was broken, and with him more than five thousand three hundred of the Lacedæmonians and their allies. After this defeat they sued for peace, and obtained it: giving hostages that they would submit to Alexander's decision on their fate. (Pausan. iii. 10. Arrian, ii. 13.)

AGIS IV., son of Eudamidas II. (B.C. 244). On his accession to the throne, at the age of twenty, at a period when the public manners had degenerated from their ancient severity, Agis undertook the task of restoring the institutions of Lycurgus. His system carried with it its best recommendation, and the sure pledge of its sincerity, in his own personal example. But unfortunately, both for himself and his country, his colleague, Leonidas, had formed his habits in the luxurious court of Seleucus, king of Syria. The manners of the mass of the people, as well as of the rich, had become tainted, and so wide as well as general had been the departure from the original pattern of conduct, that it seemed hopeless to attempt a general correction of abuses. The privileged class, to whom the name of Spartans was confined, was now reduced to seven hundred heads of families, of whom not more than one hundred enjoyed wealth; such was the effect of the inequality introduced by intercourse with strangers, and especially the Persians, and by the gains attendant on success in war. The oligarchy was rich, haughty, and licentious; the poor were oppressed and burdened with debt. These considerations suggested the immediate adoption of measures, sanctioned by the venerable authority of Lycurgus; but the event proved the hopelessness of reform, when the evils of corrupt government had worked their way into the sentiments and habits of the people. The two great features of the proposed reformation were, the renewal of the partition of the lands, and the abolition of all debts; the latter measure, which must in all cases necessarily be one of injustice, throws suspicion on the character of Agis, who otherwise might pass for an honest reformer. But the rich and luxurious, as Plutarch has it, shuddered at the very name of Lycurgus, like runaway slaves about to be led back to their masters. Agis also proposed adopting as an act of the legislature, what Cinadon, in the reign of Agesilaus, (see Agesilaus,) had attempted to effect by conspiracy; namely, to abolish the distinction between Spartans and Lacedæmonians, retaining that between the Lacedæmonians and the Periœci, or people of the smaller towns. These latter, however, were to be trained in the strict discipline of Lycurgus, and to succeed to the privileges of citizenship as vacancies occurred. In laying his proposals before the senate, Agis recommended them most strongly by the offer of the first personal sacrifice, in the contribution of his own lands and money to the common stock. His mother and his kindred followed his example. The multitude applauded: but Leonidas and the rich men opposed the plan, and persuaded the senate to reject it: the question was lost only by a majority of a single vote. To rid himself of Leonidas, Agis contrived to get Lysander appointed one of the ephori; who forthwith accused Leonidas of having violated the laws, by marrying a stranger, and residing for a time in a foreign land; two acts forbidden to the race of Hercules. Leonidas could not venture to make his appearance; he was therefore deposed, and his crown devolved to his son-in-law, Cleombrotus, who co-operated with Agis in his measures of reform. On the expiration of Lysander's office, a reaction took place. As the reformers now despaired of succeeding by mild means, Agis and Cleombrotus went to the place of assembly, plucked the ephori, now of the anti-reforming party, from their seats, and placed others in their room. This violence was not followed up by personal injury. The life of Leonidas, who had returned into the city during the short triumph of his faction, was threatened; but Agis himself protected him from assassination, meditated against him by Agesilaus, who was the uncle of Agis. The want of sincerity in this unworthy relation of the reforming king occasioned the failure of the scheme, when all its difficulties seemed to have been nearly overcome. Agesilaus was deeply involved in debt: he therefore persuaded the two kings to burn all deeds, registers, and securities in the first instance. When the division was proposed, he devised repeated pretexts for delay. Before the first measure, owing to these underhand practices, could be completed, the Achæans, who were allies of Sparta, applied for assistance against the Ætolians, who threatened to lay waste the country of Peloponnesus. Agis was, therefore, unavoidably sent to command the army, and exhibited the same republican virtues in his military office, as in his civil administration. His popularity was deservedly great; and it enabled him, notwithstanding the licentious spirit of the times, to preserve the strictness of ancient discipline. He now joined his forces to those of Aratus, whose over-caution left no room for enhancing the glory of the Lacedæmonian soldiery: but the conduct of the troops, and the rigid performance of every duty on the part of their commander, impressed both the allies and the enemy with respect for the commonwealth.

On the return of Agis, he found that a change had taken place in the condition of his country. The poor had been disgusted by finding, that although Agesilaus was again one of the ephori, the lands were not divided according to promise. Their anger was natural enough, but they directed it unjustly and unwisely. They threw themselves into the party of their own enemies, and suffered them to dethrone Cleombrotus and restore Leonidas to power. The tide of popular favour had turned against Agis, and he was compelled to fly to sanctuary. Some treacherous friends entrapped him, got possession of his person, and dragged him to prison. Being questioned by the ephori, whether he did not repent of having introduced innovations into the state? he replied, that in the face of death, he would not repent of so worthy an enterprise. He was condemned, and executed with indecent haste; the plea for this was, the danger of a rescue. One of his executioners was moved to tears. Agis, observing this mark of feeling, said, 'Lament me not; though I suffer unjustly, I am happier than my murderers.' The cruelty of the victorious party did not end here: his mother and grandmother were strangled on his body. His reign lasted only four years. His widow was forcibly taken out of her house by Leonidas, and married against her will to his son Cleomenes. Though a husband by compulsion, Cleomenes was attached to his wife, whose conversation inspired him with the desire of accomplishing the projected reform. [See Cleomenes.] (Plutarch's *Life of Agis.*)

AGISTMENT. This word is taken from an old French word *gister*, 'to lie down.' The original application of the term will appear from the explanation of the legal meaning of agistment. When the owner of land depastures the cattle of another person at a certain rate per week or month upon his ground, he is said to *agist* such cattle: and this contract is so called because the stranger's cattle are permitted *agister*, that is, to lie down, or be domiciled in the land appropriated to them.

AGNA'NO, a remarkable lake near Naples, not far from the road leading to Pozzuoli and Bajæ. Its bed is supposed to have been formerly the crater of a volcano; it is about two miles round, and entirely surrounded by hills rising in the form of an amphitheatre. Some antiquaries have started the supposition, that this lake was originally the fish pond of Lucullus' villa, that wealthy Roman having had a magnificent residence in this neighbourhood. The banks of Agnano present a striking scene of solitude; hardly any habitation is to be seen on the slope of the hills; the country is very unwholesome in summer, and the malaria is increased by the practice of the country people steeping large quantities of flax in the water of the lake. The pestilent effluvia reach high up the hills, even to the convent at the summit of Mount Camaldoli, from which there is perhaps the finest view in all the neighbourhood of Naples. Tradition says, there was formerly a town on the site of Agnano, which was swallowed up in some earthquake, the epoch of which is unknown. Near the banks of the lake are the natural vapour-baths of San Germano, which are beneficial in cases of rheumatism and gout. On the opposite side is the famous *Grotta del Cane*, a small cave in the rock from the ground of which a mephitic vapour issues, which has the power of depriving a dog or other animal of all sensation in a few minutes. There is no mention in the ancient writers, either of Agnano or of the Grotta, only Pliny the Elder says in his Natural History, that in the country about Puteoli there were vents in the ground from which deadly vapours arose. Traces of ruins of mosaic pavements, and stoves for baths, are found scattered in the neighbourhood. On the western side of the lake rises the volcanic hill of Astroni, the extinct crater of which, nearly three miles in circumference, has been converted into a royal park and preserve, planted with large trees, and abounding in game of every description.

AGNESI (Maria Gaetana) was born at Milan in 1718. When very young, she distinguished herself by the acquisition of various languages; she is said to have understood Latin, Greek, Hebrew, French, German, and Spanish. She then turned her attention to mathematics and philosophy, and at the age of 19, wrote in defence of 191 theses which were published in 1738, under the title of *Propositiones Philosophicæ*. In 1748, she published her celebrated work, *Instituzioni Analitiche ad uso della Gioventù Italiana*, in two volumes, 4to. The first volume contains the elements of Algebra, with the application of Algebra to Geometry; the second contains an excellent treatise on the Differential and Integral Calculus. In 1750, her father, who was then a professor of the university of Bologna, being ill, she obtained permission from the Pope Benedict XIV. to supply his place. She ended her career, but in what year we cannot ascertain, by retiring into a convent, and taking the veil. She died in January, 1799, aged 81.

The second volume of the *Analytical Institutions* was translated into French by D'Antelmy, with additions by Bossut, and published at Paris in 1775. The whole was translated into English, and published at the expense of Baron Maseres in 1801.

There is an éloge of Agnesi by Frisi, translated into French by M. Boulard, which we have not been able to obtain.

AGNOLO, BACCIO d', a Florentine, was at first a wood-engraver, and afterwards an architect. He was born in 1460, and had already acquired considerable reputation in the practice of his earlier profession at Florence, when he was attracted to the study of architecture, and went to Rome to pursue it among the remains of antiquity there. He appears, nevertheless, during his residence in Rome, to have continued to employ himself in his art and business as a wood-engraver, probably for the means of subsistence, and his study or shop was frequented by the most eminent men of taste and learning then in Rome. Among these were Raffaelle, Michael Angelo, Sansovino, and the brothers Sangallo.

On settling himself as an architect in Florence, Baccio was engaged in several works of importance there, and acquired notoriety of a disagreeable nature through deviations from the ordinary practice of the time. He adorned the windows of a mansion or *palazzo*, (as the Italians term the large town-house of a distinguished person,) in the Piazza di Santa Trinità, with frontispieces, and put a frontispiece, consisting of columns with a regular entablature, to the portal, in the manner, indeed, which has been so commonly practised ever since, and is at the present time in vogue, but which had been restricted to churches up to this time. All the wits in Florence set upon poor Baccio, who was lampooned and ridiculed in every possible way, for making, as it was said, a palace into a church; indeed, he was almost induced to retrace his steps, but being conscious that he had done well, 'he took heart and stood firmly.' It was a novelty, and as the biographer of all the architects says, 'like almost all other novelties, it was at the first scorned and afterwards worshipped.' But the same writer is somewhat severe on him for making, perhaps, too bold a crowning cornice to the front of this identical edifice, saying, that it looked like a boy with a huge hat on his head!

Baccio had been engaged to complete the architectural arrangements about the tholobate or drum of the cupola of the metropolitan church of Santa Maria del Fiore, which were left incomplete by Brunelleschi, and whose design for that part was lost. Baccio was about to supply what was wanting after his own invention, and had begun to cut away the toothings left by Brunelleschi in the work because they did not suit what he proposed to do. At this juncture Michael Angelo happened to come to Florence from Rome, and attacked him so violently on the unfitness of his design, that Baccio was stopped, and in consequence of subsequent disputes on the subject, the edifice, in that particular, still remains incomplete.

Baccio d'Agnolo died in 1543, being eighty-three years of age, and left a son Giuliano, an engraver and architect, who succeeded to the direction of his father's works. The most esteemed of Baccio's productions are the villa Borghesini, near Florence, and the campanile or bell-tower of the church di Santo Spirito (a production of Brunelleschi's), in Florence. By some writers, the great palazzo Salviati, in the Transtiberine portion of Rome, is attributed to this architect, but it is more commonly referred to Nanni di Baccio Bigio, a man of far inferior merit and reputation to Baccio d'Agnolo.

A'GONUS, in Ichthyology, a genus of Acanthopterygious fishes, first separated from the Cotti by Block, and afterwards adopted, by Lacepede and Pallas, under the different names of Aspidophorus and Phalangistes. The greater number of the species belonging to the genus Agonus are found in the northern Pacific ocean, particularly along the coast of Japan, and northwards as far as Behring's Straits. They are all of diminutive size, never exceeding nine or ten inches in length, and are no where used as an article of human food. One species only, the Pogge, (*A. Europæus,*) inhabits our own coast, as well as the coasts of France, Holland, Iceland, and even Greenland; it is also found in the Baltic, but according to Baron Cuvier, never in the Mediterranean, though Brunnich expressly affirms the contrary.

[Agonus Accipenserinus.]

The reader who desires a detailed description of the characters of this genus is referred to Schneider's edition of Block's *Systema;* the *Spicilegia Zoologica* of Pallas; an excellent monograph of the genus by Tilesius, in the fourth volume of the *Memoirs of the Academy of Sciences of Petersburg*, and more particularly, the *Histoire Naturelle des Poissons*, of the late Baron Cuvier and M. Volenciennes.

AGOSTA, OR AUGUSTA, is a sea-port town on the south-east coast of Sicily in the *Val di Noto.* The town was built in the 13th century, by the Emperor Frederick the Second, on a low peninsula. On its north side the peninsula is connected with Sicily by a long narrow causeway, having considerable salt ponds on each side. The harbour formed by this projection is one of the safest and most sheltered in the island of Sicily. This town suffered from an earthquake in the year 1693, by which it was nearly reduced to ruins; during the shock, the powder magazine in the citadel exploded, and the light-house was thrown into the sea. Various accounts agree in stating, that one-third part of the inhabitants were crushed to death by the falling buildings. The town has since been rebuilt on a regular plan, and in order to mitigate the evils of any similar visitation in future, the houses are all made very low. The place is slightly fortified on the land side, and is protected towards the sea by three forts, built on as many small islands at the entrance of the port. Agosta has never recovered the degree of importance which it enjoyed previous to the earthquake. The knights of Malta, during the time of their prosperity, had a considerable establishment and extensive magazines at this port. The trade of Agosta is in wine, flax, olive-oil, salt, and sardines. The remarkable caves of Timpa are in its vicinity. The town is situated eighteen miles north of Syracuse in 37° 8′ N. lat., and 15° 8′ E. long. Population said to be about 15,000.

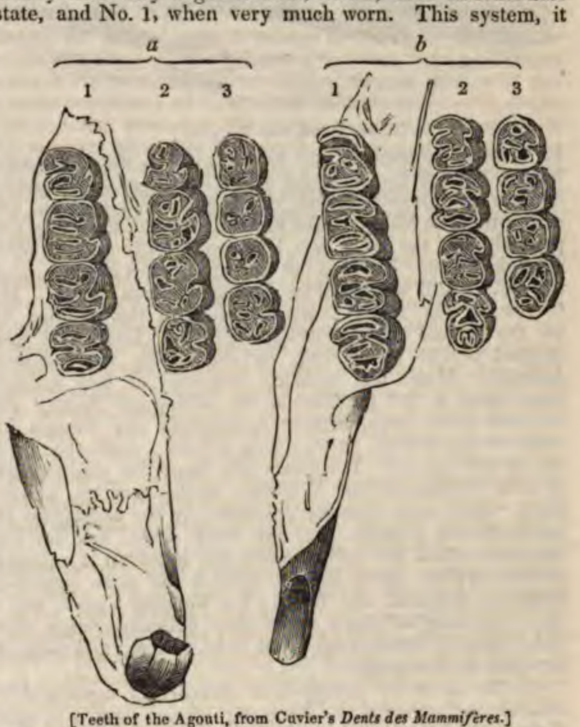
AGOUTI, (*Dasyprocta*, Illiger; *Chloromys*, F. Cuvier,) in Zoology, a genus of animals belonging to the class Mammalia and order Rodentia. The peculiar and appropriate character of the Rodentia consists in having two long incisors, or front teeth, in each jaw, with which they not only mince and triturate the hard substances which serve them for food, but which they likewise apply to a great variety of other purposes, such as the formation of subterraneous burrows, hollowing out artificial habitations in the trunks or among the roots of trees, sometimes even cutting down very large timber, as in the instance of the beaver, and generally in gnawing and destroying whatever they happen to encounter. To enable them to perform these operations, the incisor teeth, which, with these animals, are also the most important organs of mastication, are shaped something like a chisel. They are extremely sharp on the external edge, and slope abruptly towards the internal, so that the plane of the outer surface makes with the crown of the tooth a very acute angle. Neither is the enamel or hard flinty principle of the teeth dispersed through the body of these organs in waving irregular lines, as in the molar teeth of all animals which feed upon vegetable substances, but it is here accumulated in a particular part, covering the external surface of the tooth like a thin crust, so that the heart and inner edge, being composed of softer substances, (viz., common bone or ivory,) wears much more rapidly than the external surface, and thus continually preserves the sharp-edged, chisel-shape of the tooth, so essential to the economy of the animals. Leading as they do a peaceful, harmless life, and feeding principally upon vegetable substances, the rodentia are destitute of canine teeth; but in the number, form, and composition of their molar teeth, as well as in the number, separation, and moveableness of their toes, they present an almost infinite variety, and it is upon these differences that their generic characters are principally founded.

Though zoologists have not succeeded in subdividing the rodentia into natural families, distinguished by the same definite and logical characters as have been developed in some of the other orders of mammals, they admit of being distributed into small natural groups, the component parts of which are very intimately allied among themselves. Among these groups, certainly one of the most natural is that which composes the genus Cavia of Linnæus, at present divided into five natural genera, differing equally in the conformation of their organs of mastication and of locomotion. These are the capybara, (*Hydrochærus*, Brisson,) the pacas, (*Cælogenys, F. Cuvier,*) the moco, (*Kerodou*, F. Cuv.) the common cavies or guinea-pigs, (*Cavia*, Cuv.) and the agoutis, (*Dasyproctæ* and *Chloromys* of Naturalists.) Besides the large incisor or rodent teeth, the genera of this group have universally four molars in each side of each jaw, destitute of real roots, and penetrated by laminæ of enamel, which assume various forms, and appear marking the crowns of the teeth with divers irregular figures. This character, indeed, is not peculiar to the caviform rodentia, but is equally apparent in the porcupines, couendous, and other genera of the same order, but the number and form of the toes is, as far as we are aware, altogether peculiar to the present group. These are, four on the fore feet, and three on the hind, a combination only found in one other mammal, the tapir; and so invariable and essential does this character appear to be among the cavies, that the only instance in which the general rule admits of exception, is the case of the pacas, which have two small additional toes before and one behind: the supernumerary toes are mere rudiments, of no use in the functions of locomotion and prehension. Even in the qualities of their hair, these animals agree with one another, and differ from the generality of other rodentia; and their habits and economy are in most respects alike: the hair is universally of a coarse, bristly quality; they inhabit the hotter parts of South America and the West Indian Islands, and are most especially fond of low, marshy situations, and the banks of inland lakes, and rivers.

The most prominent zoological characters of the Agoutis are found in the nature and conformation of the feet and toes. The toes are provided with large powerful claws, and yet the animals make no use of them in digging or burrowing; they are pretty long and perfectly separate from one another, enabling them to hold their food between their fore-paws, and in this manner to convey it to their mouth. Like all other animals which are thus accustomed to use the fore-paws as hands, they have a habit of sitting upright upon their hind quarters to eat, and frequently also assume the same position when they would look around them, or are surprised by any unusual sound or occurrence. Their food is exclusively of a vegetable nature, and consists most commonly of wild yams, potatoes, and other tuberous roots in the islands of the different West India groups, they are particularly destructive to the sugar-cane, of the roots of which they are extremely fond. The planters employ every artifice for destroying them, so that at present they have become comparatively rare in the sugar islands, though on the first settlement of the Antilles and Bahamas, they are said to have swarmed in such countless multitudes, as to have constituted the principal article of food for the Indians. They were the largest quadrupeds indigenous in these islands upon their first discovery. The same rule of geographical distribution holds good generally in other cases; viz., that where groups of islands are detached at some distance from the mainland of a particular continent, the smaller species of inhabitants are usually found spread over both, whilst the larger and more bulky are confined to the mainland alone, and are never found to be indigenous in the small insulated lands.

Though the Agoutis use their fore-paws as hands to hold their food whilst they eat, yet their toes are nevertheless rigid and inflexible, and their claws large, blunt and nearly straight. They are consequently deprived of the power of ascending trees; and as they also do not construct burrows they wander at large among the woods, sheltering themselves beneath fallen timber, or in the hollow of some decayed tree. Here they produce and nurture their young, bringing forth, according to some accounts, three or four times in the year; according to others, never having more than a single litter in the same season, and even that consisting of not more than two or three individuals. It is probable, however, from the amazing numbers of these animals found in all the hotter parts of South America, notwithstanding the destruction made among them by small carnivorous animals, as well as by the Indians, and likewise from the close affinity which they bear to the hare and rabbit of our own country, that the Agoutis are tolerably prolific. The young are brought forth with the eyes closed, as in the case of most of the rodentia and the carnivora; but they are covered with hair, or rather small bristles, of the same colour as the mother: they soon acquire the use of their limbs and members, and learn to shift for themselves.

The hind legs of the Agoutis are considerably longer than the fore, and their pace is tolerably rapid for a short distance. But they seldom trust to speed of foot for their safety, but seek for shelter and security in the first hollow tree, or under the first rock they meet with. Here they allow themselves to be captured, without any other complaint or resistance, than the emission of a sharp plaintive note. The head of the Agouti is large, the forehead and face convex, the nose swollen and tuberous, the ears round, short, and nearly naked, and the eyes large and black. The hair is annulated in different degrees, with black, yellow, and green; it is generally coarse and bristly, like the weak spines of a hedgehog, though in one species it approaches in fineness to the fur of the rabbit; the tail is most commonly a mere naked stump or tubercle, which in the acouchy alone attains any apparent length, and is covered with a few short scattered hairs. The teeth are twenty in all; namely two incisors and eight molars, four on each side, in each jaw. The latter are all nearly of the same size, oval in figure, and with flat crowns, which exhibit the different convolutions of the enamel, as it penetrates the softer materials of which the body of the tooth is composed. It is impossible from mere description to convey an idea of the intricate figures which these convolutions assume; and we, therefore, refer to the annexed figure, where *a* and *b* represent respectively the upper and lower jaws, and the figures 1, 2, and 3, the appearances of the teeth at different ages, or after different degrees of trituration: No. 3, representing the teeth shortly after they begin to wear, No. 2, their intermediate state, and No. 1, when very much worn. This system, it will be observed, is exclusively adapted to a vegetable food; it is essentially formed for grinding and bruising, not for cutting and tearing: the stomach and intestines, therefore, which are always in harmony with the organs of mastication, are fitted only for the digestion of vegetable substances. The flesh of these animals is white and tender; it is a very common and favourite article of food in South America, and is dressed like hare or rabbit. There are four species distinctly known, and one alluded to by M. F. Cuvier in his treatise *Des Dents des Mammifères*, but of which we have no further knowledge nor description.



[Teeth of the Agouti, from Cuvier's *Dents des Mammifères*.]

1. The common Agouti, (*Dasyprocta Acuti*,) sometimes called the olive cavy, from the prevalent colour of its back and shoulders, is the size of a middling hare, being one foot eight inches in length, and about eleven or twelve inches high at the croup. The head resembles that of the rabbit, the nose is thick and swollen, the face arched, the upper lip divided, the ears round and naked, the eyes large, the upper jaw considerably longer than the lower, and the tail a naked flesh-coloured stump. The hairs of the upper and fore parts of the body are annulated with brown, yellow, and black, which give the animal a speckled yellow and green appearance on the neck, head, back, and sides; on the croup, however, they are of a uniform golden yellow, much longer than on any other part of the body, and directed backwards; the breast, belly, and inner face of the forearms and thighs are light straw colour, and the moustaches

and feet black. The general length of the hair on the upper and anterior parts of the body is about an inch, that of the croup is upwards of four inches long, and all, excepting the short coarse fur of the legs and feet, and that on the breast and belly, is of a stiff, harsh nature, partaking more of the quality of bristles than of simple hair.

2. The black Agouti, (*Dasyprocta Cristata,*) is rather improperly called the crested agouti, by M. Geoffroy St. Hilaire, since the hairs of its head and neck do not exceed those of the shoulders and back in length. It is considerably smaller than the common agouti, being about the size of a rabbit, whilst that species approaches the dimensions of the hare.

[Black Agouti, from F. Cuvier.]

Its general proportions and form, however, are the same, but the hairs of the back and sides, instead of being annulated with various-coloured rings as in that species, are nearly uniform black, whilst the long hairs of the croup are perfectly so; the belly and legs are equally covered with short dark hair. There is not any appearance of crest, and the tail is still shorter than in the common agouti. M. Cuvier in the *Règne Animal,* considers this species to be the female of the former, and M. Desmarest has marked it with an asterisk, as considering the question doubtful. Males and females, however, of both species have lived in the gardens of the Zoological Society for the last three years, without undergoing any change in colour or appearance, thus proving beyond a doubt that they are distinct species. It appears also from the observations of MM. Desmarest and F. Cuvier, made upon two individuals which were formerly possessed by the menagerie of the Jardin des Plantes, that the black agouti has but six mammæ, whilst the other species (the common) is reported to have twelve. Both seem to inhabit the same climates, Surinam, Guyana, and Brazil; the common agouti, however, appearing to have a rather more extensive range, and to be likewise found in the West India islands, and even as far south as Paraguay.

3. The Acouchy (*Dasyprocta Acuchi*) is considerably smaller than either of the foregoing species, and is at once distinguished by the greater length of its tail, which is upwards of two inches in length, not much thicker than a crow's quill, and covered with short scattered hairs like those on the tail of a rat. In other respects it is of the same form as the Agoutis; has the same naked round ears, the same large black eyes, and the same olive-green colour mixed with yellow and black. The hairs of the croup are not so long as in the Agoutis, but are perfectly black, and all the under parts of the body, the breast, belly, and interior of the arms and thighs, straw-coloured with a tinge of red. The hair of the legs and feet is short and black, and that of the body much finer in quality than the hair of the Agoutis. Stedman informs us that this species is very rare in Surinam: in Guyana it is more common, though less so than the Agouti, and according to the report of De la Borde is there called a rabbit, whilst the Agouti is denominated the hare. It also inhabits the islands of St. Lucia and Grenada, lives in the woods like the Agoutis, but its flesh is said to be insipid and dry.

[The Acouchy, from Buffon.]

4. The Mara or Patagonian Cavy (*Dasyprocta Patachonica*) is an animal as yet but imperfectly known to naturalists, and seems, from many details of its description, to form the connecting link between the present genus and the Chinchillas and Lagostomys. It is considerably larger than the Agoutis, measuring two feet six inches in length, and one foot seven or eight inches high at the croup. The ears also are essentially different, being three inches and a half in length, erect and pointed; and this circumstance, together with the length and elevation of the legs, gives the mara more the appearance of a small stag or antelope, than of a rodent animal. The hair also is materially different from that of the Agoutis, and approaches in texture and quality to the fine rich furs of the Bischaco and Chinchilla. On the head, shoulders, and back, it is greyish-fawn colour mottled with white, darker on the loins and hips, and terminating in a well defined curve over the croup, within which the colour is almost a jet black. All the under parts of the body are white; and this colour is separated from the greyish-fawn of the back and sides by a yellowish band, which passes along the flanks as in certain antelopes and gazelles. Under the chin and on the throat the colour is white, and there is a band of the same colour, and of a semicircular form, situated between the back and the hinder part of the thigh, above the groin, and surrounding the dark colour of the croup. The male and female are in all respects alike; the latter has four mammæ, and is said to bring forth but two young ones at a litter, which she conceals in the warrens of the Bischaco, till they acquire strength to follow her abroad and learn to shift for themselves.

[Patagonian Cavy, from Lesson.]

This species inhabits the open plains and wilds of Patagonia, as far south as the Straits of Magellan, where, according to M. Lesson, it is called Mara by the natives. It is often mentioned as a hare in the voyages of Sir John Narborough, Commodore Byron, and other navigators, who found it in great plenty about Port Desire, on the eastern coast, and to whom its flesh was a welcome and wholesome substitute for the dried and salt provisions, which formerly composed the only food of the sailor. The maras are said to go in pairs, to keep entirely in the open pampas or plains; they never form burrows, but couch in a lair by the side of some plant or shrub, run with great velocity for a short distance, but are easily fatigued. In the pampas, south of Buenos Ayres, Azara informs us that they are pursued on horseback, and killed with two heavy iron balls connected by a long cord, which the natives are very expert in throwing, and seldom miss their aim.

AGRA, CITY. The capital city of the province of Agra is situated on the south-west bank of the river Jumna, 27° 12′ N. lat. and 77° 56′ E. long. It was originally an inconsiderable village, but in the beginning of the sixteenth century was much enlarged by the Emperor Sekunder Lody, who bestowed on it the rank of an imperial city and made it the capital of his dominions, under the name of Badulghur. Half a century later, the city was further enlarged by the Emperor Akbar, who built here an extensive palace, and again changed its name to Akbarabad. This city continued to be the seat of the Mogul government until the year 1647, when Delhi was declared the capital by the Emperor Shah Jehan, from which period the decline of Agra may be dated. Shah Jehan, during his residence at Akbarabad, built a most superb mausoleum, as the cemetery of his favourite wife the Begum Noor-Jehan, about three miles from the city. This building, which is called the tâge-mahal, or crown of edifices, is composed of white marble, and is raised on an elevated terrace of white and yellow marble. It contains a central hall, within which are the tombs of the Begum and of Shah-Jehan himself, and around this hall are several smaller apartments and corridors. This mausoleum, the finest probably in the world, is said to have cost 750,000*l.*; it is kept by the British government in excellent order, together with its beautiful garden of trees and flowering shrubs. In this respect it contrasts favourably with the condition of the city, which is, for the most part, in a ruinous state,—the splendid palace of Akbar 'being used as warehouses, armories, offices, and lodging-rooms for the garrison.'

The houses in Agra are built of stone, and are very lofty, while the streets are so narrow as scarcely to allow a carriage to pass through them. The city contains many public baths, caravanseries, and mosques.

Agra was taken, in 1784, by the Mahratta chief Madajee Scindiah, and was retained by him until 1803, when it was captured, after a siege, by the forces under Lord Lake. It is now the seat of British government for the province. The Hindoo inhabitants hold the city in great veneration, as the place of the *avatâra*, or incarnation of *Vishnu*, under the name of Parasu Rama. Agra is one hundred and thirty miles, travelling distance, from Delhi, and eight hundred and thirty miles from Calcutta by way of Berbhoum.

AGRA, PROVINCE, a soubah or province of Central India, bounded, on the north, by Delhi; on the south, by Malwah; on the east, by Oude and Allahabad; and on the west, by Ajmeer. It lies between 25° 35′ and 28° 18′ north latitude. Its length is about 250, and its breadth about 180 miles. The province is divided into thirteen circars, or districts, viz., Agra, Calpy, Kanage, Cowl, Gualior, Irej, Sanwan, Narwar, Mundlayer, Alvar, Tejareh, Narnoul, and Sehar; and these districts are subdivided into 203 pergunnahs, or hundreds, containing, together, 40 considerable towns and about 340 villages. The chief towns and fortresses are Alvar, Bhurtpoor, Deeg, Mathura, or Muttra, Etaweh, Gualior, Gohud, Calpy, and Narwar. In the *Institutes of Akbar*, compiled by Abul Fazl, in 1582, it is stated, that the revenue of the soubah of Agra amounted to about 1,615,625*l.* sterling, and that it furnished 50,600 cavalry, 477,570 infantry, and 221 elephants. The chief rivers of the province are the Ganges, the Jumna, and the Chumbul. There are also some smaller streams; yet the country is but ill-supplied with water, and except in the immediate neighbourhood of the rivers, the water required for agricultural purposes must, in the dry season, be procured from wells. For this reason rice is but little cultivated. North of the Chumbul, the country is, for the most part, flat and badly timbered; but, on the other side of that river, and towards the north-western quarter of the province, the surface is somewhat hilly and more plentifully covered with trees. The climate, during a part of the year, approaches to temperate, and in the winter months may even be pronounced cold; but during the prevalence of hot winds, to which the whole of Central India is occasionally liable, the heat is insupportably great, and the climate, in consequence, unfavourable to European constitutions. These winds are seldom of long continuance.

The soil is, in general, particularly well adapted for the production of indigo, the cultivation of which may be extended almost indefinitely; the same may be said of sugar and cotton. The country between the Ganges and the Jumna, called the Dou-ab, is the most fertile part of the province, and furnishes all these articles for export.

There are but few mineral productions to be noticed in the province. It is said that copper has been discovered, but not under circumstances favourable to the working of the mines. There are marble quarries in the vicinity of Futtehpore. The breed of horses is superior to those of Bengal, and the more southern and eastern provinces. A good deal of coarse cloth is manufactured, principally for home use, in several of the circars; fine muslins and silks were formerly made, but these branches of industry have now much diminished.

Agra is not so thickly peopled as Bengal. It is said to contain not more than 6,000,000 inhabitants. All the territory which lies to the east of the Jumna, together with the city of Agra and a small district round the same, are in the immediate possession of the East India Company. The country north of the Chumbul is held by rajahs or native chiefs, in strict alliance with the British. South of that river, the territory is mostly held by, or tributary to, the Mahrattas. The natives are, for the most part, a handsome and robust race, and superior, in these respects, to the Bengalese. They are composed of a mixture of Hindoos and Mohammedans. Hindostannee is the language used in common intercourse, but the Persian is the official tongue, and is spoken by the higher class of Mohammedans.

AGRAM, a fortified town on an eminence near the Save, 45° 49′ N. lat., 16° 1′ E. long. It is about 150 miles nearly due south of Vienna. Agram is the chief town of Austrian CROATIA, and the residence of the Viceroy of Croatia and Slavonia. The town consists of three parts, the upper, the lower, and the part called Opatowina. It is the seat of a bishop, has an academy, a grammar-school, and a convent of Franciscans. Agram carries on some trade along the Save, which joins the Danube at Belgrade; and is also the great market for the sale of Hungarian wheat and tobacco, and Bosnian pigs. The population is stated at above 17,000.

AGRARIAN LAW was the general title of any law among the Romans which related to the *ager publicus*, or public domain. As the subject of agrarian laws constitutes perhaps the most important element in the history of the Roman republic, and as an utter misconception of their application has pervaded, till of late years, every work upon the subject, especially the popular writings of Hooke, Ferguson, &c., it seems desirable to place before the general reader a brief account of those more correct views which have been established by the researches of Heyne, Niebuhr, and Savigny.

Ever since the revival of letters it has been a universal error to look upon the agrarian laws, with which the names of the Gracchi and others were connected, as attempts to limit the amount of landed property that any individual might hold; and such an interference with private rights would indeed afford strong ground for condemning any statesman who could be the author of such a proposition; and any state where such a proposition could be favourably received. In the frenzy of the great French Revolution, there were indeed political fanatics, who, following the advice of Macchiavelli and Montesquieu, were willing to enact an agrarian law of this extravagant nature; and so much stress was laid upon the examples of Roman history, that Heyne, in March 1793, availed himself of the opportunity offered to him by the installation of a new prorector in the University of Göttingen, to address to that body a paper entitled *Leges agrariæ pestiferæ et execrabiles*, (see his *Opuscula*, vol. iv. p. 351,) in which he successfully contended that the laws so called among the Romans, instead of interfering with private property, solely applied to the lands of the public domain. Heeren and Hegewisch carried the inquiry further; but for the fullest and most satisfactory investigation of the whole subject we are indebted to Niebuhr and his friend Savigny.

As the victorious arms of the Romans extended their authority over one state of Italy after another, the right of conquest gave them a title to the lands of the conquered; but, except in cases of strong provocation, as in the defection of Capua in the second Punic war, it became the clemency of the conquerors to restore a part of the territory to the unfortunate owners. Yet a portion would perhaps always be reserved and added to the public domain. With regard to the disposition of the territory so acquired, we will not go back to an earlier date than the Servian constitution, which gave to the *plebes* or commonalty a share in the government, though an inferior one, with the patricians. The disposition of the conquered land was then, we may perhaps say, fourfold. Part was given in full property to religious uses, and part was sold by the quæstors for the supply of the treasury. The plebeians, who constituted the most important part of the army, received assignments of fixed and equal portions in full ownership, never perhaps exceeding seven jugers (*i. e.* between four and five acres) to each individual. These lands were often given under the form of a colony, the parent state sending a body of the citizens to occupy some conquered town, or to found a new one. In all cases the boundaries of lands so assigned were marked out according to the strict principles of Roman limitation, and placed under the religious sanction of the augury. But a large portion of the territory which fell into the hands of the conquerors in the issue of a successful war must often have been in a state of utter desolation, for devastation by fire and sword was a constant and leading feature in ancient warfare; and in a country where the olive and the vine form an important branch of agriculture, such desolation was not easily repaired. Thus large districts were unfit for distribution among the plebeians, or for sale by the quæstors. Moreover, much of the mountain land, and even of the unhealthy plains in Italy, was, as it still is, adapted solely for pasturage, and therefore equally unfit for partition, though far superior in immediate value. The disposition of this unappropriated land, which constituted the permanent public domain, led to a singular mode of occupation. An edict was issued, giving authority, most probably to the patricians alone, to cultivate these lands, but with the full understanding that the state reserved to itself the ownership, and might at any time resume possession,—a right which was from time to time exercised. Yet, though the occupants had no title whatever as against the state, they appear to have been protected against individuals by the interdicts of the prætor, and a branch of law entitled *caussæ possessionum.* Under this protection these lands often passed from father to son by a species of permitted inheritance, or as dowries to daughters, or were even transferred to other citizens by purchase; and in this way even plebeians, it would appear, might come into the occupation of them. But, no matter through how many hands the lands might pass, the tenure to the last occupier was as precarious as to the first; and, of course, this was always taken into account in estimating the value. On the other hand, the occupier was subject to certain restrictions and payments. He could not legally hold, at least after the Licinian law, more than 500 jugers (about 333 acres) of this public land; on the public pastures he was limited to 100 head of great, and 500 of small cattle; and he was bound to employ a fixed number of freemen. Some of these restrictions indeed did not always exist, but it seems highly improbable that some regulations of the kind should not have existed from the very beginning, if only to protect one patrician from another. But whatever doubt there may be on this subject, the state was always entitled to the payment of a tenth upon all grain, and a fifth on the olives and the wine, besides some charge, we know not how determined, for the use of the common pasture land. The technical terms used with regard to these possessions were as follows: the lands themselves were called *agri occupati, a. occupatorii, a. possessi, a. concessi, a. arcifinales,* or generally *possessiones.* The holder or *possessor* was said to have the *usus* of them; and the payment he made to the state was the *fructus* or *vectigal.* Instead of collecting this branch of the revenue directly, it was the practice to farm it out, which was expressed by selling or letting the *jus vectigalis* or *fructus;* and in the same sense they used the phrase *agrum fruendum locare,* or even more briefly, though somewhat ambiguously, *agrum locare.*

It must be confessed, indeed, that in this view of the first occupancy of the public domain, there is still something to be cleared up; for a mere edict, such as we have spoken of, without qualification or restriction, would have been little better than an invitation to a general scramble. Yet, however this may be, it is established incontrovertibly that the possession was simply permissive. If the original occupancy was founded in collusion, the case against the patricians will only be the stronger.

In the various usurpations of the patrician body the restrictions enumerated above were little attended to. The vectigal was rarely paid. While the plebeian was serving in the army abroad, the portion of the public domain possessed by him—and this could only be through purchase—was violently or fraudulently seized by a powerful neighbour. Large districts were monopolized by single holders. It was by them found more profitable to cultivate the land by slaves than by freemen, who were always liable and often called upon to perform military service. Those who held the chief power in the government conspired to deny the title of the state to resume their possessions; and even when new conquests added to the domain, the most desperate efforts were made to resist all further assignments of land to the plebeians, that is, to the very veterans who had effected the conquests. To redress these grievances, or rather to moderate them, agrarian laws were from time to time brought forward; but, we repeat, these laws never interfered with private property. The wealthy might hold land really their own to any amount. The sole object which the reformers had before them was to check usurpations of the public domain.

We cannot trace the subject historically through the whole existence of the republic, but a few remarks may still be useful. If we look at the birth, the station, the conduct, and the character of the distinguished men whose names are connected with the promulgation of agrarian laws, we shall find little reason for considering them as demagogues. Spurius Cassius indeed lived in a time when we can place little reliance upon the truth of Roman history; but he was himself a patrician, he had thrice been consul, and had thrice triumphed; and though he was eventually tried and executed for treason, the trial took place not before a plebeian court, as is generally stated, but, as Niebuhr has established, in the *Comitia Curiata,* where the patricians themselves, whose usurpations he had contended against, were at once his accusers and his judges. For understanding the true character of Licinius Stolo, and the wisdom and justice of his legislation, we will only refer to the forthcoming number of Niebuhr's third volume. In the time of the Gracchi, it may be thought by many that injustice and tyranny had obtained a title by prescription; but though there may be a question about the policy of the reforms they were endeavouring to introduce, no candid reader of Roman history can doubt the purity of their intentions, or the baseness of the majority among those who resisted them by revolution and assassination. Except the presumed guilt of supporting these agrarian laws, not even their enemies could find a blot in the characters of the two sons of the virtuous Cornelia. Velleius was no friend to democrats, but he says, speaking of the elder Gracchus, *Vir alioqui vita innocentissimus, ingenio florentissimus, proposito sanctissimus, tantis denique adornatus virtutibus, quantas perfecta et natura et industria mortalis conditio recipit.*—('A man in other respects (*i. e.* except in his opposition to the usurpations of the patricians) as to his life most blameless, in ability most distinguished, in principle most upright, in fine adorned with every virtue in as high a degree as man can attain to, when the best gifts of nature are improved by discipline.')—At the same time his opponent Octavius, and his murderer the Pontifex Maximus, Scipio Nasico, were actually offenders under the very law which Tiberius was endeavouring to enforce. On the other hand, the consul Opimius, who headed his party in the premeditated massacre of the younger Gracchus and three thousand of his defenceless countrymen, and then erected a temple to Concord, was afterwards convicted of sacrificing the interests of his country for the gold of Jugurtha. For a full examination of the agrarian laws of Rome, see Niebuhr's *History,* translation by Hare and Thirlwall, vol. ii., pp. 129—173; and among the ancient writers, Appian's *Civil Wars,* book i. c. 7—27; Plutarch's *Lives of the Gracchi;* Dionysius and Livy; Cicero's speech against Rullus, &c.

AGREEMENT, a mutual bargain, contract, or covenant. In its most extended sense, it comprehends a large proportion of the transactions of civilized man in the mutual intercourse of society, and may even be said to form the basis of civil society itself. In a more limited sense, it gives rise to those obligations which it is the object of all government to enforce. The following is a short outline of the law of England, in reference to the latter class of contracts: it may, however, be noticed that, as it appears to be founded, for the most part, on the obvious wants of society and the ordinary maxims of natural justice, its provisions will be found to coincide, in their general features, with the laws of civilized communities.

1. *Assent* is the essence of an agreement: hence the parties to a legal and valid contract must be in a situation to testify their free assent to it. Thus lunatics, infants, and married women are, for obvious reasons, deemed incapable of binding themselves by any engagement. In some few transactions of urgent necessity,—as in the purchase, for example, of those articles which nature, or the conventional usages of society, have rendered fit and necessary, the contracts of the two former classes of persons are obligatory on them; or, in the case of a married woman, on her husband. In the same manner, fraud, intimidation, or other undue advantage taken by the party who has attempted to secure to himself a benefit by an agreement, will discharge the party who, from ignorance or the operation of external force, has yielded an apparent assent to it.

2. The *subject* of agreement must not be tainted with illegality; for it would be evidently repugnant to common sense that the law should be called upon to enforce perform-

ance of any act which it has expressly forbidden, or which contravenes its general policy.

3. An agreement, in order to secure the aid of the law in carrying it into effect, must have certain qualities mutually beneficial to the parties, or must be entered into with certain prescribed solemnities. Courts of justice cannot be called upon to give effect to every idle or inconsiderate promise. An agreement must either be contracted by a formal instrument in writing, sealed and openly acknowledged by the party who has bound himself by it, and which is technically called a *deed*, or *specialty contract;* or if contracted in a less formal manner, by word or otherwise, it must appear that the parties derive from it reciprocal benefit. This is the meaning of lawyers when they affirm that a *parole* agreement (*i. e.* an agreement not contained in a deed) cannot be legally enforced, unless there be a sufficient *consideration* to support it. Thus A. cannot found legal proceedings against B., in respect of any promise made by B. to A., unless by the terms of the original agreement A. was either to confer some reciprocal advantage upon B., or was to put himself to some specific disadvantage at B.'s request. Upon this principle it is that, by our law, a promise to make a voluntary gift can never be enforced; but there is a continuing right, in the party promising, to retract his promised donation, until the gift is actually completed. An agreement, thus defective for want of consideration, is called a '*nudum pactum,*'—a phrase borrowed from the Roman law, though used in a sense somewhat different from that which it bears in the Roman code.

4. The *form* of agreements has in some cases been regulated by positive law. The most remarkable instance is that which was introduced by the Statute of Frauds, in the reign of Charles II.; by which it is enacted that contracts, in certain cases, shall not be available, unless there be some memorandum or note of them in writing, duly signed by the parties to be charged, or their agents. Doubts have been entertained on the efficacy of this provision in the prevention of frauds; yet similar precautions have, we believe, been adopted in other countries, and the legislature has, in our own time, been induced to extend its application to cases not within the scope of the original statute.

The rules respecting the *construction* of agreements; the various modes by which parties may be released from the performance of them; and the circumstances under which they may excuse or justify non-performance, belong rather to works exclusively adapted to legal students than to a sketch like the present.

With regard to the mode of enforcing agreements, the law has provided two different remedies, to which the injured party may resort, according to the nature of his case. He may either seek a pecuniary compensation for the breach of the agreement in the courts of common law; or, in cases where such compensation is inappropriate, he may obtain from the courts of equity a decree that the party offending shall perform his agreement specifically.

See further Blackstone's *Comm.*, b. ii., c. 30.—Fonblanque's *Treatise of Equity*, vol. i.—Bacon's *Abridgment*, tit. '*Agreement.*'

AGRICOLA (CNÆUS JULIUS) was born on the 13th of June, in the year 38 A. D., at Forum Julii, now Fréjus, a city at that period of considerable celebrity. (See FREJUS.) The father of Agricola was Julius Græcinus, a writer of some eminence on agriculture, and distinguished, as a senator, both for his eloquence and his integrity. But his virtues were the cause of his destruction. The emperor Caligula being desirous to get rid of his father-in-law, M. Silanus, called upon Græcinus to undertake the accusation which was to be the pretext for his destruction. This disgrace Græcinus refused to incur, and consequently he met with the same fate as the unfortunate Silanus. Agricola was an infant at the time of his father's death. His mother was Julia Procilla, and thus on both sides Agricola was connected with the Julian house. This fact, however, affords no evidence of any connexion by blood; and it is most probable that the name was originally obtained by the ancestors of Agricola as freedmen of Julius Cæsar, or Augustus. We find them at any rate connected with a colony, Forum Julii, which appears to have been founded by the former, for it existed in the time of Cicero; and again the grandfathers of Agricola on both sides held the dignity of procurator or chief fiscal officer in the provinces, which was not uncommonly bestowed on the favourite freedmen of the Cæsars. After receiving his education at Massilia, (Marseilles,) the principal seat of learning in Gaul, he was sent to Britain, where he served under the immediate eye of Suetonius Paulinus, one of the ablest generals of Rome; and his service in this island included perhaps the most critical period during the whole Roman occupancy, viz., the grand insurrection under Boadicea (61 A. D.), when, availing herself of the absence of Suetonius in his attack upon the sacred island of the Druids (Anglesey), she fell upon the three chief settlements of the Romans—Camalodunum (commonly supposed to be Maldon in Essex), St. Albans, London, and massacred seventy thousand men; for which Suetonius soon after exacted ample vengeance. In 62 he returned to Rome, where he married Domitia Decidiana, a lady belonging to one of the first families. He was now elected quæstor, and received Asia for his province, the wealth of which too often tempted the cupidity of Roman officers: and, on the present occasion, the Proconsul Salvius Titianus (a brother of the future emperor Otho) would willingly have made a compromise with his quæstor for mutual impunity; but Agricola did not yield to the temptation. During the latter part of Nero's reign distinction was dangerous, and Agricola, well knowing the jealousy of the emperor, endeavoured—even when holding the offices of tribune and prætor—to avoid all appearance of ostentation and ambition. On the accession of Galba (68) he was selected as a commissioner to examine the state of the treasures belonging to the temples, and to restore to them whatever had been taken away; for under Nero the valuable gifts consecrated in the temples had been repeatedly seized to fill the empty coffers of the prince. How far Agricola was engaged in the civil contests which ensued between Otho and Vitellius does not appear. At the outset of this war his mother was murdered by a detachment from Otho's fleet which landed in Liguria, and ravaged the property of the family near Intemelium (Vintimiglia). As Agricola was hastening to pay the last offices to his mother, he learned that Vespasian had been proclaimed by the legions in the east. He instantly declared in his favour, and was soon rewarded by the command of the twentieth legion in Britain. On his return to Rome (about 73) he was enrolled by the emperor among the patricians, and soon after appointed governor of Aquitania, a province which, since the distribution of the empire made by Augustus, included all the south-western part of Gallia, from the Pyrenees to the Loire. This appointment he held for nearly three years, and his successful administration of this peaceable province proved him to possess abilities beyond those of a mere soldier. He was recalled to receive the still higher honour of the consulship. His daughter, born during his quæstorship in Asia, was now betrothed to the celebrated historian, C. Cornelius Tacitus, and the next year she was given to him in marriage. Agricola, at the expiration of his consulship, was appointed governor in chief of the island where he had already twice served in an inferior capacity. He proceeded thither about the year 78, but the date cannot be fixed with any certainty. During his last absence from Britain the command had been in the hands of Petilius Cerialis and Julius Frontinus, the former of whom had subdued a part of the territory of the Brigantes (Yorkshire, Lancashire, &c.), and the latter had entirely reduced the Silures in South Wales. Agricola passed seven or perhaps eight summers in Britain; in the first of which he added North Wales and the sacred island of Anglesey to the Roman province. By the end of the fourth campaign, the whole island south of the Clyde and the Forth was secured to the Romans by a line of forts running from the one æstuary to the other. Every summer extended the dominion of the Roman arms, but it was only in the last year of his government that he entirely broke the spirit of the Britons, by the defeat of Galgacus on the Grampian hills. At the close of this campaign, a Roman fleet, for the first time, sailed round the island, as if to mark the extended boundary of the Roman empire. The splendid successes of Agricola were, however, unpalatable to the suspicious Domitian, who could not fail to observe how ready the people would be to contrast them with his own pretended victories over the Germans. Agricola was honourably recalled, under the pretext of being sent as governor to Syria. By order of Domitian he entered Rome at night, and after a cold reception by the emperor he quietly retired into private life. When his consular rank a few years after entitled him to the proconsulship of Asia or Africa, he wisely declined an appointment which had been fatal to the previous possessor. He died on the 1st of September, A. D. 93, in the fifty-sixth year of his age, not without some suspicion of poison. His property was left between his wife Domitia, his only child, (married, as we have already said to Tacitus,) and the emperor Domitian. The latter appeared highly pleased at this mark of esteem, but, as the historian observes, a good father never bequeaths his property to a good prince. All that we know of Agricola, with the exception of a single chapter in Xiphilin (66. 20) which is very inaccurate, is from the pen of Tacitus.

AGRICOLA (RODOLPHUS), one of the most learned and remarkable men of the fifteenth century, was born at a village, variously written Bafflou, Baffeln, Bafflen, Baffel, or Baflo, two or three miles from Groningen in Friesland, about the end of August 1443, not in 1442 as often stated (see the inscription on his tombstone as given in M. Adam's *Apograph. Monument. Haidelburgens.* p. 22). In a short notice of Agricola by M. Guizot, in the *Biographie Universelle*, it is said, but we do not know upon what authority, that his name was properly *Huesmann.* His first master is also there said to have been the famous Thomas à Kempis. After distinguishing himself at school, he proceeded to the college of Louvain, where he remained till he took his degree of M.A. He was then solicited to accept a professorship in that college; but he declined an office which would have prevented him from visiting the chief seats of learning in other countries. According to a custom common with the students of that age, he set out on his travels and came to Paris. After remaining here for some time, he proceeded to Italy, and arrived at Ferrara in 1476, where he resided during that and the following year, and attended the prelections of Theodore Gaza on the Greek language. He also extended his own reputation by giving a similar course on the language and literature of Rome. The favour of the duke, Hercules D Este, and the admiration of the most famous scholars of Italy were liberally bestowed upon the accomplished foreigner, who used to contend, we are told, in amicable rivalry with the younger Guarino in writing Latin prose, and with the Strozzis in verse. After visiting Rome and some of the other cities of Italy, he left that country, probably in 1479. On his return to Holland he appears to have occupied a chair for a short time in the university of Groningen, and he was also chosen a syndic of that city, in which capacity he spent about half a year at the court of the emperor Maximilian I. In the year 1482 he removed to Heidelberg on the invitation of Joannes Dalburgius, the bishop of Worms, whom he had taught Greek, and by whom he was appointed to one of the professorships in the university of Heidelberg. The remainder of his life seems to have been spent partly at Heidelberg and partly at Worms, where he lodged in the house of his friend the bishop. At the request of the Elector Palatine, who greatly delighted in his conversation, he composed a course of lectures on ancient history, which he delivered at Heidelberg, the Elector being one of his auditors. He also after coming to reside in the Palatinate, commenced the study of the Hebrew tongue, under the tuition of a converted Jew, whom his friend the bishop kept in his house for that purpose. In this new study Agricola had made great progress, when a sudden attack of illness carried him off at Heidelberg, on the 28th of October, 1485, at the early age of forty-two. There was certainly no literary name out of Italy so celebrated as that of Agricola during his age; and, if we except Politian and Mirandola, perhaps not even Italy could produce a scholar equal to him. The most eminent cultivators of classical learning in the next age have united in placing Agricola among the first of his contemporaries. We need only mention Cardinal Bembo, Ludovico Vives, the elder Scaliger, and, above all, Erasmus. Agricola indeed may be regarded as the immediate forerunner of the last great writer, and in some degree as the model on which he was formed. Agricola, in the same manner as Erasmus, appears to have clearly discerned many of the ecclesiastical abuses of his time, and to have anticipated the revolution in the opinions of men that was at hand, although he refrained from doing anything to urge on the crisis. If Agricola did not write Latin with all the exactness of Erasmus, his compositions are not less distinguished by a natural ease and perspicuity of style, and often by an eloquence which is altogether classic in spirit at least, if not in form. Erasmus has himself told us that in beauty of diction he placed him on a level with Politian, and in majesty before him. Besides his skill in ancient learning, Agricola was a skilful practitioner of the arts of music and painting. His collected works were published, as it is commonly stated, in two volumes 4to. at Cologne, in 1539, under the title of *R. Agricolae Lucubrationes aliquot, &c.* According to Gesner's *Bibliotheca Universalis*, and the *Bibliotheca Belgica* of Foppens, the principal contents of this collection are his three books De Inventione Dialectica, some letters, orations, and poems, and some translations from Aphthonius, Lucian, Isocrates, and other Greek authors. It does not appear to contain, as commonly stated, his abridgment of Universal History. The work De Inventione Dialectica is the most celebrated of Agricola's performances. It has been repeatedly printed with ample scholia; in 1534 a compendium of it, by Joannes Visorius, appeared at Paris; and an Italian translation of it was published in 4to. at Venice, in 1567, by Oratio Toscanella. It is considered to have been one of the earliest treatises which attempted to change the scholastic philosophy of the day. Morhof speaks of it as having anticipated in several respects the Logic of Peter Ramus. In the injunctions given by Henry VIII. to the University of Cambridge, in 1535, the Dialectics of Agricola and the genuine Logic of Aristotle are ordered to be taught instead of the works of Scotus and Barlæus; and in the statutes of Trinity College, Oxford, founded some years later, we find a similar recommendation. Besides the works already mentioned, the following authorities may be referred to for further information respecting Agricola; Bayle, *Dictionnaire;* Baillet, *Jugemens des Savans; Vitæ Germanorum Philosophorum*, a Melchiori Adamo;—*Vie d'Erasme*, par Burigny, Paris, 1757, vol. i., p. 17; *Vita R. Agricolæ*, autore Ger. Geldenhaurio Noviomago, in *Virorum eruditione et doctrina illustrium vitis*, Francfort, 1536, p. 83, &c. See also an interesting letter on the habits and character of Agricola, from Melancthon, dated Frankfort, 28 March, 1539, in the edition of Agricola's works published at Cologne.

AGRICULTURE. The important subject of the cultivation of the earth may be conveniently regarded in three distinct points of view, namely, practically, historically, and politically.

If we were to attempt, as is done in several *Cyclopædias*, to give a connected account of the practice, the history, and the statistics of Agriculture, many Numbers of this publication would be insufficient even for a slight sketch. We shall, therefore, only point out here some of the larger divisions in which the subject will be arranged.

1. The *Practice* will be found principally under the heads Arable Land, Draining, Farm, Grass Land, Live Stock, Orchards, Woods.

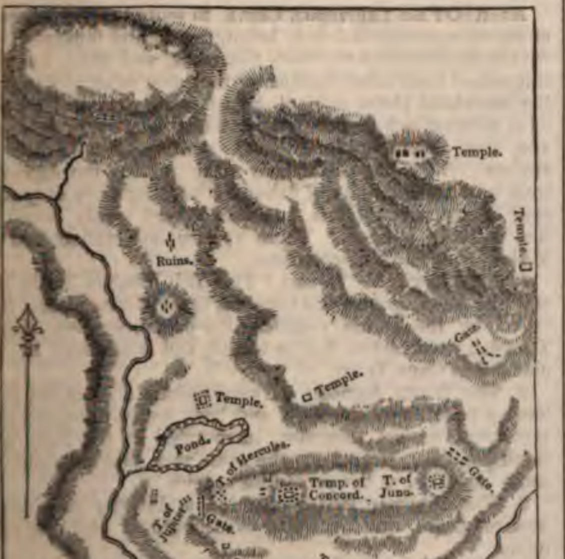
2. The *History* will be treated under the head British Husbandry, which will include a comparative account of the progress of other nations.

3. The *Statistics and Political Economy* will chiefly be embraced under the heads Corn-Laws, Cottage Allotments, Food of Labourers, French Economists, Markets, Poor-Laws, Rent, Tithes.

AGRIGENTUM, now called Girgenti, a Sicilian city, distinguished by the magnificence and gigantic size of its ruins, which bear certain testimony that the stories related of its extraordinary wealth in old times are not entirely without foundation. It was called by the Greeks Acragas, and by the Romans Agrigentum. It is situated on the southern coast of Sicily, about two and a half miles from the sea, 37° 17′ N. lat. 13° 28′ E. long. and was a colony from Gela, another city lying on the same coast, to the eastward, founded about Ol. 50, B.C. 580. We first hear of it in connexion with the well-known name of Phalaris, tyrant of Agrigentum, of whom many improbable stories are told. The duration of his power, variously stated by ancient authors, is placed by Dr. Bentley from Ol. 53, 4, to Ol. 57, 3 (B.C. 565 to 550). It seems that he was a prince of considerable ability, who, having made himself master of the state, like Pisistratus or Dionysius, was called *tyrant*, a word having in itself no signification of cruelty, but merely expressing the assumption of unconstitutional or absolute power. He was destroyed in a popular tumult, by a general attack of the people, (Cic. Off. ii. 7,) and after his death a democratical government was established for about sixty years, during which we find in extant history no mention of Agrigentum.

Anterior to the year 480, we find Theron ruling the city, with the title of prince, (δυνάστην, Diod. xi.) known by two odes of Pindar, composed in honour of victories gained by his chariots in the Olympic games. Theron was a mild and popular ruler. He reduced Himera, a town on the northern coast of Sicily, the tyrant of which, Terillus, sought help at Carthage, and gave occasion to the first important attempt of that city to extend its dominions in Sicily. A large army of Carthaginians passed over, and besieged Himera, but was defeated with great slaughter by the combined force of Agrigentum and Syracuse. A vast number of prisoners were taken and made slaves on this occasion, insomuch that it is stated, probably with some exaggeration, that 400 fell to the share of many individual citizens, and yet the greatest part were retained for the public use, and employed in those stupendous buildings, of which we still admire the remains. Theron died Ol. 77, 1, B.C. 472, and Thrasydæus, his son, a man of licentious and cruel temper, succeeded. He provoked a war with Syracuse, in which he was defeated, and his power probably being shaken, he was expelled by the Agrigentines, who again established a democracy.

When the Athenians invaded Sicily in the Peloponnesian war, Agrigentum remained neuter. We find few notices of it again till B.C. 408. At that time the city flourished, according to Diodorus, in wealth and luxury, such as no other state but Rome itself had exhibited. Of the means by which such wealth was acquired, we know nothing, except that extraordinary fertility is ascribed to the soil, and that the resort of foreigners makes it likely that it was a great commercial depôt. The number of citizens is stated by Diodorus (xiii.) at 20,000, and of foreigners settled there 180,000 more, a number probably much exaggerated. In B.C. 406, this prosperous city was again attacked by Carthage. The residents were supported by a body of Italian mercenaries, commanded by a Lacedæmonian, Dexippus; and a powerful diversion was made from without by Syracuse. But civil discord and insubordination rendered fruitless a resistance, which for some time was spirited, and might have been successful. The Carthaginians completed lines of circumvallation; and when the place was reduced to extremity by hunger, the bulk of the citizens passed the enemies' lines in a winter night, and reached Gela in safety. The town was preserved by Hamilcar or Imilcon, the Carthaginian general, for winter quarters, but razed in the following spring: the pictures, statues, and most valuable spoil was taken to Carthage, the rest sold. The vacant town and territory of Leontini was given by the Syracusans to the fugitives.



Agrigentum, from Capt. Smyth.

Of the subsequent history of Agrigentum only scattered notices remain. It is said, by Plutarch, to have been rebuilt by Timoleon, which must have been between the years B.C. 344 and 337. We find it stated, indeed, that the Agrigentines united with Dionysius the elder, when he declared war against Carthage, Ol. 95, 4. B.C. 397: but this may, perhaps, refer only to the Agrigentines established in Leontini. Ol. 117, 4. B.C. 309, they made an attempt to recover their ancient power in Sicily, and for a time seemed to prosper, but desisted from the attempt in the second year, in consequence of experiencing a defeat from the Syracusans. The prosperity of the city at a somewhat later period is rendered probable by a statement in Diodorus, (xxii. ecl. 14,) that Pyrrhus received from the Agrigentines 18,000 foot and 800 horse 'equal to the Epirot troops,' when they admitted him into their city, about B.C. 280. In the first Punic war the state adhered to Carthage. During the struggle in Sicily between the Carthaginians and Romans, it was taken, retaken, and taken again; and suffered very severely in all these changes. Little more is known of its history, and there would be no profit in attempting to combine the scattered notices of a city which never again filled an important part. For an account of the modern town, see GIRGENTI.

The situation of Agrigentum is said by Mr. Wilkins to be one of the most beautiful in Sicily. 'At the foot of the high mountains which bound the plains of the Acragas, a low ridge of hills extends from east to west. The southern side gently slopes towards the river, while the northern and western sides fall much more steeply towards the Hypsa, which still flows, though with a current much diminished.' (*Magna Græcia.*)

The most remarkable objects mentioned by Diodorus in his account of the town, (Book xiii. c. 82.) are the temple of Jupiter Olympius; and an artificial lake, seven stadia, or near a mile in circumference, and twenty cubits, or thirty feet deep, fed constantly by running streams, well stocked with fish, which were eaten at the public entertainments: the pond was also a favourite haunt of swans. This, before the time of the historian, was filled with mud, in consequence of neglect, and turned into orchard or garden ground, which afforded a considerable revenue to the town. He also mentions the tomb of Theron as a considerable work. The temple of Jupiter is said by Diodorus to have been the largest in the island: indeed, except the temple of Ephesus, it was the largest Grecian building applied to sacred purposes. Its dimensions, as given by him, are—height, exclusive of the platform, 120 feet; length 340; breadth 60. It was of the Doric order, but *apteral*, that is, it had no external portico, the interval between the columns being filled up by wall. This deviation from the general practice arose probably from the impossibility of finding stones large enough to serve as epistyles; for the distance from centre to centre of the columns being 30 feet, a series of masses of stone of that length, and of corresponding depth and thickness, would have been required, had not the superincumbent entablature been sustained by a continued wall. As it is, many blocks of the entablature weigh eight tons and upwards. The columns are *engaged*, that is, little more than half their mass projects from the wall. The circumference of the external and visible part is 20 feet, the diameter, as given by Mr. Cockerill, 13. Their proportions cannot be exactly ascertained; they are conjectured by Mr. Cockerill, from other examples at Agrigentum, to have been $4\frac{3}{4}$ diameters in height. The echinus of each (that is, the swelling part of the capital) was formed by two stones, each a quarter of the whole capital, had the pillar been disengaged. Two of them at least remain, each weighing (by computation we presume) $21\frac{1}{3}$ tons. These enormous masses were raised to the height of 70 feet from the ground. To the inside of the building, as Diodorus expresses it, they are square, and 12 feet in diameter, that is, there is a series of pilasters within, 12 feet broad, corresponding in position with the external columns. The columns were built in courses of masonry, not single blocks, so that in fact they formed an integral part of the wall. The flutings are said by Diodorus, and the account is verified by recent travellers, to be wide enough to contain a man in their hollow, as in a niche. When the town was first taken by the Carthaginians, the temple was completed except the roof, and this deficiency was never supplied. In the eastern pediment was sculptured the war of the Giants: in the western, the siege of Troy. Within, the temple was divided into what we may call a nave and two aisles; and it may assist the reader's comprehension to state, that according to Mr. Cockerill's measurements, (whose description of the temple, in the 4th vol. of Stuart's *Athens*, is the latest and best,) the height of the nave was 18 feet more than that of the nave of St. Paul's, and its breadth 2 ft. 2 in. greater. The walls of the interior were strengthened by massive pilasters, supporting an entablature upon which stood a row of *Atlantes*, as the Greeks called male figures when thus applied. These colossal figures were about 25 feet high, and supported an upper entablature, which rose about 110 feet above the floor of the temple. Fragments enough to restore one of these giants were collected by Mr. Cockerill. The width of the chest is more than 6 feet, the head is 3 ft. 11 in. high, and 3 ft. wide. The style of sculpture approaches that of the Æginetan marbles: the giants must, however, be considerably later in date. Fazellus says, that 'one part connected with three giants and some columns was long standing, but fell, December 9, 1301, and the common people still call the spot the Palace of the Giants.'

A thin coating of plaster, resembling the finest marble, covered the whole building. The breadth, as given by Diodorus, is clearly wrong, unless we suppose him to mean the cell, or nave of the building, in which case he is not very far from the true dimensions as ascertained by measurement. We may here remark, that some modern works give the height, as stated by Diodorus, at 220 feet. Wesseling, however, reads 120, and the other is so glaringly out of proportion, that there can be no doubt which is right. The dimensions, given in English feet by Mr. Cockerill, are—

	ft.	in.
Extreme length of basement	369	5
——— breadth	182	8
——— of cell	68	6
——— temple within the walls	142	6
Height of podium or basement	9	6
From the basement to the top of the capitals	61	6
Entablature	25	6
Tympanum	23	6
Total height	——120	

Of this splendid building, with the exception of the basement, scarce one stone remains above another. Traces of the walls, however, have been discovered by excavation, enough to enable the skilful architect to determine the ground-plan with accuracy. Not a single column remains standing, but two capitals are still visible on the ground,—one with a portion of the entablature attached,—which excite the wonder of the visiter by their gigantic size.

We have described at length this the most remarkable of the Agrigentine ruins in size and construction: of the others, we must speak very briefly—they differ little from other Greek remains. At the south-east angle of the ancient city, stood the remains of a temple formerly dedicated to Juno Lucina. Further to the west, stands the temple of Concord, in better preservation, owing to its having been converted into a Christian church. More recently it was restored according to the original design, by the late king of Naples. The portico is perfect, and the columns in good preservation. Both these temples are of the Doric order, and nearly of the same size and plan. Both are *peripteral*, or surrounded by a portico, consisting in each of six columns in front and thirteen on the side, and their dimensions are about the same—length 124 feet, breadth 54. They are situated on the immediate edge of an abrupt rock, and form most striking objects from the plain below. A good view of them and the surrounding scenery is to be seen in Mr. Wilkins' *Magna Græcia*. Of the temple of Hercules but one pillar remains; of that of Æsculapius, only three. The area of the fish-pond is still visible; it is now a garden, as in the time of Diodorus. The form is traceable, and the dimensions seem to be larger than those given by the historian. Other remains of antiquity exist, and among them, one is said to be the tomb of Theron; but there is nothing further to call for particular description.

Many stories of the extraordinary wealth and profuseness of the Agrigentines are told, which are not without interest; they may be summed up in the pithy observation of Empedocles, himself a native of the city, that 'the Agrigentines built as if they were to live for ever, and feasted as if they were to die on the morrow.'

AGRIMO'NIA is the name of a plant of the rose-tribe, to which the English give the name of herb agrimony. It is known from all the other genera of the same tribe by its having only two or three pistilla enclosed in the deep tube of its calyx, from seven to twenty stamens, and small-notched petals.

[Agrimonia Eupatoria.]

The common species, *Agrimonia eupatoria*, is an erect, hairy, herbaceous plant, frequent by the sides of hedges in fields, on the skirts of woods, and in similar situations all over England. Its lower leaves are interruptedly-pinnated, with the leaflets of an oval form, and coarsely serrated. When bruised, they yield a slight, but pleasant aromatic odour. The stem is nearly simple, and a foot and half or two feet high. The flowers, which are small and yellow, are succeeded by little bur-like fruits.

The leaves, which are astringent and aromatic, have been found useful in the preparation of fever-drinks, and for the cure of slight inflammation in the mouth or throat; on this account agrimony is always reckoned one of our wild medicinal plants, and is often employed as an ingredient in herb teas.

AGRIOPES (*Agriopus, Cuv.*), in ichthyology, a genus of acanthopterygious fishes, belonging to the family which M. Cuvier denominates *Joues Cuirassés*, and which are distinguished from other families of the same order, by having the suborbital plates extending backwards over the cheeks, so as to cover either the whole or the greater part of them, and thus defending them, as it were, with a buckler or cuirass. But what particularly distinguishes the Agriopes from most other genera of fishes, is that they have only nine rays in the pectoral fins, a number very rarely found in this class of animals. Three species are enumerated by MM. Cuvier and Volenciennes.

1. The *Agriopus Torvus*. This fish inhabits Table Bay and the seas around the Cape of Good Hope, where it is called by the Dutch colonists *Zee-paard*, or Sea Horse. This fish exceeds two feet in length, and is common in the markets of Cape Town.

2. The Warty Agriope, (*A. verrucosus*,) is so called from having the skin of the head and body entirely covered with prominent conical tubercles, surrounded at the base with small papillæ. It grows to the same size, and inhabits the same localities, as the preceding species.

3. The *Agriopus Peruvianus* is found in the neighbourhood of Lima, and grows to the length of eight or nine inches.

AGRIPPA (HENRY CORNELIUS) a remarkable personage, who may be ranked with his contemporaries, Paracelsus and Cardan, as at once a man of learning and talent, and a quack. It may be added that each of the three was probably to a certain extent the dupe of his own pretensions. Agrippa was born at Cologne, of a noble and ancient family, on the 14th of September, 1486. His first employment was as secretary at the court of the Emperor Maximilian, after which he served in the wars in Italy, where, having repeatedly signalized himself by his bravery, he obtained the honour of knighthood. About his twentieth year he seems to have assumed the character of a scholar, and to have commenced a wandering life. The profession which he took up was that of a physician; but he allowed himself also to be regarded as an alchemist, an astrologer, and even as a practitioner of magical arts. Not satisfied even with this extensive range, he thought proper to set up likewise for a great theologian, as well as to indulge himself with occasional excursions into other departments of literature and science. The effect in that age of all this pretension, supported as it was by unquestionable talent and by real acquirements of great extent, was to raise Agrippa, for a time at least, to high estimation and importance. Pressing invitations were sent to him by several crowned heads that he would enter into their service—by our Henry VIII. among the rest. He appears to have visited England before this, one of his pieces being dated from London in 1510. His excessive imprudence, however, was continually involving him in difficulties; and especially, having by some of the effusions of his satiric spirit provoked the enmity of the monks and the church, he experienced the consequences to the end of his days. After having led for many years what may almost be called a fugitive life, this singular character died at Grenoble, in 1535. He had been thrice married, and had several children. The works of Agrippa were published in two volumes, octavo, at Leyden, in 1550, and also at Lyons in 1600. The most remarkable of them, and the only one which is now remembered, is his Treatise *On the Vanity of the Sciences*, which is a caustic satire on the kinds of learning most in fashion in that age. Bayle has dedicated a very long article to Agrippa, to which we refer those of our readers who wish for more information respecting him. See also Gabriel Naudé's *Apology for the Great Men who have been suspected of Magic*.

AGRIPPA (HEROD, son of Aristobulus), king of Judea. [See HEROD.]

AGRIPPA (HEROD) son of the above. [See HEROD.]

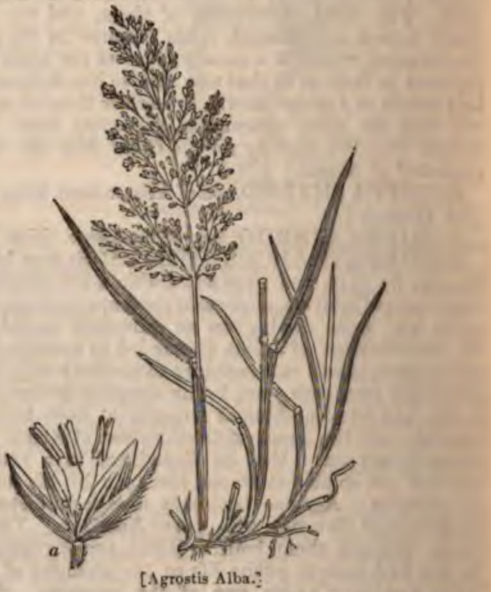
AGRIPPA (MARCUS VIPSANIUS) was born about the year 63 B. C., and thus was within a few months of the same age as Octavius, afterwards the emperor Augustus, with whom his whole destiny was so intimately united. When the assassination of Julius Cæsar led to a renewal of civil distractions, it was extraordinary to see the young Octavius, only in his twentieth year, boldly stepping forward into public life, and proving himself superior at once to the ablest generals and the most subtle statesmen of Rome. Not less extraordinary was it that he should find in a youth of his own age one so able to second him both by his counsel and his energies. Agrippa is already named in history as the companion of Octavius, while yet at Apollonia. The death of Cæsar brought them both to Rome, and Agrippa appears for the first time in public life as the promoter of an accusation against Cassius, one of the assassins. Again, in 40 and 41, when he was still only twenty-two years of age, we find him playing a highly important part in the war against Lucius Antonius; and indeed the capture of Perusia, which brought that war to a conclusion, was in a great measure due to the exertions of Agrippa, who covered the siege, on the eastern side, against the united forces of Ventidius, Pollio, and Plancus. In his consulship, 37 B. C. (or perhaps the year before his consulship,) he added to his reputation by a considerable victory over the Aquitani, and rivalled the glory of Julius Cæsar by leading a second Roman army across the Rhine. A large portion of this year was employed on the part of Augustus in preparing a fleet to oppose Sextus Pompeius, whose decided superiority at sea enabled him to blockade the whole coast of Italy, so that it was difficult for Augustus to provide a fleet, much more to train a body of sailors to the manœuvres of naval warfare. The fertile genius of Agrippa was able to meet the difficulty. By cutting a passage through the celebrated barrier of Hercules, which separated the Lucrine Lake from the sea, he converted that lake and the interior lake of the Avernus into a serviceable harbour, giving it the name of Portus Julius. In the following year he commanded the fleet of Augustus, in the victory off Mylæ; and afterwards in that more decisive contest which annihilated the power of Sextus Pompey, and gave to Augustus the full possession of Sicily. In the year 33, though already of consular rank, he held the office of ædile, his administration of which was distinguished by the restoration of the numerous aqueducts, and the erection of fountains throughout the city. In the naval victory off Actium, (B. C. 31,) which left Augustus without a rival in the empire, Agrippa was again the admiral of the successful fleet. In reward for these services he shared with Mæcenas the full confidence of Augustus, who associated him with himself in the important task of reviewing the senate; and in B. C. 28 again raised him to the consulate, giving him, at the same time, in marriage his own niece, the sister of the young Marcellus. Agrippa had indeed been previously married to the daughter of Cicero's friend, Atticus, by whom he had a daughter, Vipsania, afterwards the wife of Tiberius. Attica may have been dead, or it is not improbable that he divorced her to make room for Marcella. A third consulate awaited him the year following, in which he dedicated to Jupiter, in commemoration of the victory near Actium, the celebrated Pantheon, which remains to the present day, perhaps the most beautiful specimen of Roman architecture. It is now called, from its form, *Santa Maria della Rotonda*, but still bears the inscription, *M. Agrippa L. F. Cos. tertium fecit*. In 25 he assisted Augustus in the reduction of the Cantabri, and afterwards had the honour of representing the emperor at the marriage between the unfortunate Julia and Marcellus, who seemed thus marked out as the successor of Augustus. Yet the notion of any claim, founded upon hereditary descent, was not yet established among the Romans; and the splendid deeds of Agrippa, independently of his connexion with Marcella, gave him in some respects a superior title. A rivalry sprang up between them, which was encouraged by the ambiguous conduct of Augustus, more especially during his severe illness in 22, when, apparently on his death-bed, he publicly sent his ring to Agrippa. On the recovery of the emperor, Marcellus regained his influence, and Agrippa was sent by Augustus into honourable exile, as governor of Syria. Death in a few months removed his rival, and he was not merely recalled to Rome, but, at the request of the emperor, divorced his wife Marcella to marry the young widow Julia. In 19 he finally subdued the Cantabri, who had again been in arms for more than two years. Agrippa was now looked upon as the undoubted successor of Augustus; and in the following year was so far associated in the imperial dignity as to share the tribunician power with the emperor for five years. In 17 he proceeded a second time to the East, where his administration seems to have given general satisfaction, more especially among the Jewish nation, who benefited largely by his protection. On his return from that part of the world, his last military duty was to quell an insurrection among the Pannonians, for which his presence was sufficient. In Italy he received a renewal of the tribunician power for a second period of five years, but lived only a few months. He died in March, B. C. 12. His family, by Julia, were the two young Cæsars, Caius and Lucius, Julia, Agrippina, and Agrippa Postumus, born, as his name imports, after the death of his father; and it has been observed that every one of these came to a premature end. (Appian, Plutarch, Dion, Suetonius, &c.)

AGRIPPINA, the daughter of M. Vipsanius Agrippa and Julia, the only child of Augustus, married Germanicus, the son of Drusus, and nephew of Tiberius, to whom she bore nine children. Of these three died in their infancy, but among the remaining six were Caligula, afterwards emperor, and the second Agrippina, the mother of Nero. On the death of Augustus (A. D. 14), Germanicus and his wife were with the army on the banks of the Rhine, where they had much difficulty in restraining the mutinous soldiery from proclaiming Germanicus in opposition to his uncle. On this occasion Agrippina, by her determined bearing, shewed herself worthy of her descent from Augustus, and the following year she had again an opportunity of evincing the same spirit, in a general panic occasioned by an exaggerated report, that the army of Cæcina had been cut off by Arminius, and that a large body of the successful Germans were on the point of crossing the Rhine, and inundating the Gallic provinces. A proposition was made to destroy the Roman bridge over the river, but Agrippina, in the absence of her husband, prevented this disgraceful expedient. In the year 17, the disturbed state of the East afforded the emperor a pretext for recalling Germanicus from the scene of his successes in Germany. Agrippina accompanied her husband, and was with him in Syria when he fell a victim, at least such was his own conviction, to the arts of Piso and Plancina. Germanicus was not without suspicion that Piso and his wife had been urged on by the emperor and his mother, Livia, and under this feeling he implored his wife to restrain her proud temper, and submit to the evil times. Disregarding his prudent advice, she at once proceeded to Italy, and at Brundisium seemed to court the attention of the people as she left the vessel with the youthful Caligula and her youngest infant, bearing herself the funeral urn of Germanicus. The whole tenor of her conduct was such as to call upon her the anger of Tiberius, and when her cousin Claudia Pulchra (A. D. 26) was about to be the object of a prosecution encouraged by the emperor, she ventured to express her resentment to him in person in no measured terms. Agrippina had now remained in widowhood for seven years, when she requested the emperor to take pity on her single state and give her a husband. But Tiberius knew too well that the husband of Agrippina would be a dangerous enemy, and he parted from her without giving any answer to her pressing entreaties. The artifices of Sejanus completed the breach between them. By his agents he induced her to believe that there was an intention on the part of Tiberius to remove her by poison, and Agrippina, not accustomed to conceal her feelings, for ever offended the emperor, by plainly exhibiting to him her suspicions. She was banished to the island of Pandataria, and at last closed her life by starvation, October 18th, in the year A. D. 33. Her two eldest sons, Nero and Drusus, were also the victims of Tiberius. (Tacitus, Suetonius.)

AGRIPPINA, the daughter of Germanicus and the Agrippina of the preceding article, was born in the chief town of the Ubii, which she afterward raised to the rank of a Roman colony, calling it after herself *Colonia Agrippinensis* (now Cologne). She was but fourteen years of age when Tiberius gave her in marriage to Cn. Domitius Ænobarbus, by whom she had a son, who at first bore the name of his father, but afterwards under that of Nero became Emperor of Rome. After the death of Domitius, her disgraceful conduct was made by her brother Caligula a pretext for banishment: but on the accession of Claudius, she was recalled from exile and became the wife of Crispus Passienus. There seems to be some doubt whether Passienus was her first or second husband, though the probability is in favour of the latter supposition. By assassinating her husband Passienus she soon made herself again a widow, and now directed her efforts to gaining the affections of her uncle, the Emperor Claudius. Such a connection was held to be incestuous even among the Romans, but on the death of Messalina, the complaisant senate, influenced by the intrigues of Agrippina, affected to threaten the emperor with compulsion if he refused to take a step so essential to the welfare of the state (A. D. 50). Claudius yielded, and for the fifth time entered the state of matrimony. The control of the beautiful Agrippina over her aged husband was unbounded, and her first object was to secure to her own son those expectations to which Britannicus, the son of Claudius by the infamous Messalina, was more equitably entitled. The marriage of Domitius to Octavia, daughter of the emperor, and his adoption by the emperor himself, from which he derived the name of Nero, at once placed him above Britannicus; and in the year 54, Agrippina completed the object of her ambition by poisoning her imperial husband. Her son, now at the head of the empire, was not willing to allow his mother that share of the authority which she was desirous of assuming. Her power over him disappeared; and though for a time she partially recovered it by means of an incestuous intercourse with him, the beauty of Poppæa finally destroyed even this influence; and in the sixth year of his reign Nero determined under the encouragement of Poppæa to remove his mother from the world by her own arts. But it was not easy to poison one, who, familiar herself with poison, was ever on her guard. Nero, therefore, changed his course. After an unsuccessful attempt to effect her death near Baiæ by means of a vessel with a false bottom, which had been prepared for the purpose, she was openly dispatched by assassins (March, 60 A. D.). Her last words as she presented herself to the sword of her murderer were *Ventrem feri*, Strike the womb which gave birth to such a son. To enumerate all her debaucheries, all her murders, and other crimes, would require a much larger space than we think it necessary to assign to them. We will only add, that she wrote some commentaries of which Tacitus availed himself for his historical writings. They are also quoted by Pliny, vii. 8. (Tacitus, Suetonius, Dion.)

AGRO'STIS is a genus of grasses, consisting of a considerable number of species with loose-branched, capillary panicles of flowers, and a creeping habit. Among British grasses, it is at once known by the glumes (*a*), or outer scales of each flower, being two in number, unequal in size, of a membranous texture, and containing but a single floret; while the paleæ, or inner scales, are short, very thin, almost transparent, and two in number; the larger of them occasionally having an awn at its back.

Two species only are natives of this country,—one of which, *A. vulgaris*, is found everywhere in dry, exposed, barren situations, and is of very little value to the farmer, except for its earliness; the other, *A. alba*, is equally abundant in marshy places, where it forms a valuable pasture. Under the name of Irish florin grass, this species has been the object of much attention from experimental agriculturists, some of whom, as Dr. Richardson, have extolled its qualities very highly as a marsh-fodder; but the experience of others does not confirm their opinion; nor does it appear to thrive in England to the degree that is represented in Ireland, where its vigour is such as to have led to the belief that the Irish plant is a distinct species, called *A. stolonifera*. In England it is best known, along with *A. vulgaris*, under the name of quitch, or quicks, and is generally extirpated as a troublesome weed, in consequence of the rapidity with which, by means of its creeping, rooting, vivacious stems, it spreads and overruns pasture and garden-ground.



[Agrostis Alba.]

AGUE. In treating of the individual diseases to which the human body is subject, it would be out of place in this publication to enter into the details which are proper and indeed necessary in works purely medical. All at which we can aim is to endeavour to convey a clear and correct conception of the nature of each disease, the signs by which its approach is denoted, the symptoms which demonstrate its existence, the circumstances which predispose to it, the causes which actually excite it, the precautions by which its attack may be averted, and the remedies which experience has shown to be the most effectual in curing it.

With the exception of those who have studied medicine as a profession, even the educated class in this country are grossly ignorant of everything relating to this subject. Yet there is no reason why sound knowledge may not be acquired by every man on this subject as well as on chemistry, for instance. That any one who does not study medicine with a view of practising it as a profession, should make himself so familiar with its details, as to be able to dispense with the assistance of the physician when either himself, or any one in whom he takes an interest, is afflicted with a serious disease, is not indeed to be expected, and the attempt would be quite absurd. But the more real knowledge any person can acquire on subjects of this class, the better he will be able to guard against the ordinary causes of disease; the more surely he will know, at the very first moment of its attack, when any serious malady assails him; the better he will be able to communicate with his physician and his physician with him; and the more effectually he will be enabled to co-operate with whatever plan of treatment may be adopted for the removal of his disease.

For these reasons we conceive that there is no part of our undertaking likely to be attended with greater benefit to the public, than that of rendering intelligible, in all its practical bearings, to the unprofessional reader, the nature, the causes, and the treatment of the more important diseases which afflict, and shorten, and destroy human life.

Of these diseases, the first of which we have to treat, is that termed Ague, a disease of no slight importance, though happily the peculiar interest which once attached to it, at least in this country, from its continual recurrence and general prevalence, is now greatly diminished. Ague belongs to the class of febrile diseases, and is indeed commonly considered as a paradigm or example of fever in general. Fevers are divided into three great classes. In the first the morbid phenomena that constitute the disease continue for a certain length of time; then they wholly disappear: after having been some time absent they again recur, and this repetition and return of the phenomena alternate with one another for many times. The period that elapses between the cessation of the febrile phenomena and their recurrence is called an intermission. Such fevers, then, as are attended with a cessation or intermission of the febrile symptoms for an observable space of time, are for this reason called *intermittent fevers* or *agues*. This is the first class. In the second class the febrile symptoms do not altogether disappear, but merely diminish in violence; they do not *intermit*, they only *remit*; for this reason this second class of fevers are called *remittent fevers*. In the third class, during the whole course of the disease, there is not only no retrocession of the symptoms, but no notable diminution of their violence. Such as the phenomena are when the fever is completely formed, such they continue to be with scarcely any variation until its close. For this reason this class of fevers is denominated *continued fevers*.

The concourse and succession of phenomena which constitute a fever is called a paroxysm. An intermittent fever, or an ague, is therefore a fever consisting of a succession of paroxysms, between each of which there is an intermission more or less complete.

The phenomena which constitute a paroxysm of fever are the following: The person is affected first with a loss of mental vigour, commonly indicated by inaptitude to attend to his usual avocations, or by dullness or confusion of mind. If not simultaneously with, very shortly after this mental debility there comes on a sense of physical weakness. The patient is languid, listless, disinclined to move, while every movement is performed with difficulty, and the effort to move is exhausting. The muscles or organs of motion are not merely weak—they are, at the same time, the seat of several uneasy sensations; the muscles of the extremities, and of the back especially, are affected with the sensation of soreness, as if they had been over-exercised, and this soon increases to decided pain, which is often very severe.

The next train of symptoms are ushered in by pallidness of the face and extremities: the features shrink; the bulk of the external parts is diminished; and the skin over the whole body is in a morbid state, as if drawn tight. Some degree of coldness is now felt, which at first is so slight as scarcely to be noticed, but at length the patient is fully conscious of a sensation of cold, which he commonly feels first in his back, but which thence extends over the whole body. This sensation of coldness increases until it becomes so severe as to produce a tremor in the limbs, amounting sometimes to trembling and shaking, and almost always producing distinct shivering.

From the first approach of the mental and physical languor, the pulse becomes weaker than in health. As the sense of cold comes on the weakness of the pulse is still greater, and it is at the same time always more frequent than natural; often irregular, and sometimes intermittent. The respiration also is shorter, feebler, and more frequent than in a state of health. The appetite fails; there is sometimes even an aversion to food: frequently the loss of appetite is succeeded by a sense of nausea and sickness, which occasionally increases to vomiting, and with the matter vomited there is, for the most part, a mixture of bile. From the commencement of the paroxysm there is generally some degree of thirst, which increases in urgency as the sensation of cold advances, being always proportioned to, and probably arising from, the dryness and clamminess of the mouth and fauces. Not the secretions of the mouth alone, but all the secretions of the system are diminished. The excretions also are lessened in quantity, and especially the urine, which is scanty and nearly colourless, and the alvine evacuations are usually altogether suppressed. Even in this stage, headache may come on, but it usually does *not* appear until the following.

These symptoms having continued for some time, at length disappear, and a remarkable change takes place in the character of those that succeed. The sensation of cold gives place to that of heat, and a temperature far greater than that of health prevails over the whole body. The face which had been pallid now becomes flushed and red. The eyes which had been dull and heavy, are now more bright and glistening than natural. The features of the face and the other parts of the body recover their usual size and become even more turgid. The pulse becomes more regular strong, and full, the respiration fuller and more free, and the nausea and vomiting are less urgent: if before there were pain in the head, it now increases in severity; if there were none, it is now sure to come on, and while the sensibility is increased, the intellectual operations are more and more disordered.

By degrees these symptoms also pass away, and are succeeded by a different train. A moisture now breaks out first on the forehead, which by degrees extends over the whole body. As the perspiration flows, the heat abates; the pulse becomes slower and softer; the respiration more free; the nausea and vomiting cease; the thirst diminishes; the secretions and excretions are restored; most of the functions return to their ordinary state, and the patient is left comparatively free from disease, feeling only weak and exhausted.

Such are the phenomena that constitute a febrile paroxysm, and such is the order of their succession, and they obviously constitute three distinct states, or, as they are called, stages or fits; viz., the cold, the hot, and the sweating stage.

After one such paroxysm has remained for a certain length of time it ceases; after it has ceased for a certain length of time, the same series of phenomena again arises, and observes the same course as before, and this alternation is repeated many times. It has been already stated, that the length of time from the end of one paroxysm to the beginning of another is called an INTERMISSION, while the length of time from the beginning of one paroxysm to the beginning of the next is termed an INTERVAL.

Different names are given to the different varieties of this fever according to the length of the *interval*. If one paroxysm be succeeded by another within the space of twenty-four hours, the ague is termed a quotidian; if after forty-eight hours, a tertian; if after seventy-two hours, a quartan; if after ninety-six hours, a quintan. Those with longer intervals are usually termed erratic. The most common form is a tertian; the next most common a quartan; the next a quotidian; the least frequent a quintan. Agues are likewise divided into vernal and autumnal, the vernal beginning in February, and the autumnal in August. There is a great difference in their character. The vernal in general are milder and easily cured, while the autumnal are often severe and obstinate.

It sometimes happens that two intermittents attack the same person at the same time, and the ague is then said to be complicated. The most common complication is the case in which two tertians or two quartans attack simultaneously. What is called the double tertian, for example, consists of two tertians, each of which attacks at its regular time, and consequently the paroxysm occurs every day. This form of ague is distinguished from the quotidian, by comparing the paroxysms with each other. Though a paroxysm occur every day, yet if they be carefully observed it will be found that the alternate paroxysms only resemble each other, while if the paroxysm of a preceding day be compared with that of a succeeding day, some manifest difference will be observable. There may also be another form of the double tertian; namely, with two paroxysms on one day, and another on the following day: or there may be a triple tertian, with two paroxysms on each alternate day, and one only in the intervals. The double quartan also varies. It may occur with two paroxysms on the first day, none on the second or third, two again on the fourth day, or with a paroxysm on the first day, another on the second, but none on the third.

But whatever be the form of fever, the nature of it is essentially the same: yet the form is of some consequence, as denoting the severity and tendency of the disease; for a quartan is far more obstinate than a tertian, while a quotidian is apt to change into a continued fever. Quartans, for the most part, appear in autumn, while tertians are the most common in spring.

Whatever be the form of fever the duration of the pa roxysm is different in almost every different case. The longer the paroxysm the shorter the intermission; the shorter the intermission the longer the paroxysm. An extension of the period of the intermission, or a postponement of the period of attack, is in general a favourable event, denoting that the disease is declining; on the contrary, a prolongation of the paroxysm, or an anticipation of the period of attack, marks an increase in the severity of the disease, and is a sign that the intermittent is about to lapse into a remittent or into a continued fever.

From the preceding history of the disease it is clear, that the distinguishing character of intermittent fever is the regular return of the paroxysm at a fixed period, the entire cessation of it after a certain time, and the renewal of it after a specific interval, according to the species of the ague. Nevertheless, though these distinct intermissions and accessions are always apparent when the ague is regular, yet in the most severe and formidable cases it entirely loses its intermittent character and assumes a remittent, or even a continued form.

Innumerable cases, which are commonly considered and treated as continued fevers, are really of the nature of intermittents, and of this the older physicians, who had so many more opportunities of witnessing this malady in its more formidable aspect than the physicians of the present day, were fully aware. ‘Intermittents,’ says Sydenham, ‘take their names from the intervals between the fits. This is sufficient to distinguish them, if the seasons of the year wherein they happen, namely spring or fall, be considered; but some of these have no very visible character whereby they may be distinguished from continued fevers, though they really participate of the nature of intermittents. In general the character of spring intermitting fevers is sufficiently obvious; but when autumnal intermittents come early, namely, in July, and are common, these do not immediately assume their own proper shapes, for they imitate continued fevers so well, it is hard to distinguish them. But the violence of the constitution of the season being a little quelled, about the end of autumn, they put off their disguise, and then openly appear to be intermittents, either tertians or quartans, as indeed they really were at first. And if this be not carefully observed we shall be deceived in our prescriptions, while we mistake fevers of this kind which are to be accounted intermittents, for real continued fevers.’

The apparent change of character or type here stated, dependent on the severity of the disease, is constantly observed. If a fever, truly of an intermittent nature, be of a bad kind, it often commences with the form of an alarming and dangerous continued fever, but as the disease declines and becomes milder, the intermission becomes apparent, and the true nature of the malady manifest, while, if an intermittent commences under its own form, but in its progress becomes severe, it often changes into a disease which cannot be distinguished from a continued fever.

There is nothing in the nature of disease more curious and inexplicable than this property of periodicity. During the intermission what becomes of the malady? Why after a specific interval does it uniformly recur? Physicians have endeavoured to refer this singular phenomenon, which, if it were not so clearly seen would not be credible, to the principle of habit. Dr. Cullen endeavoured to show that there is in the human constitution a diurnal exacerbation, occurring towards evening, very analogous to the febrile state, and that the recurrence of the febrile paroxysm is referrible to this diurnal habit. But were this diurnal exacerbation fully established as a fact, which is not the case, it would not account for the regular return of the paroxysm of an intermittent fever, which, as we have seen, is commonly of the tertian type, and which, therefore, returns not every day, but every alternate day, and not in the evening but at noon. The regular return of the appetite for food at a given hour; the regular return of the desire for sleep; the regular return of the alvine evacuation, which it is so important to the health to cherish; even the facility with which articulate speech is pronounced, and the formation of the gait or air of a person by which each individual is distinguished from every other, these among innumerable others are examples of that law of the animal economy by which, when any motions, whether voluntary or involuntary, are performed two or three times in succession, the same motions are easily excited again. But to no such law can the phenomenon in general be referred, for the difficulty is not to account for the renewal of motions once excited, on the reapplication of the cause that produces them, but to explain why a cause which is always present, that of the malady, acts vehemently for a given time, ceases to act at all for a given interval, and then regularly commences at the termination of that interval. We have not advanced a single step towards the elucidation of this matter beyond the point at which Sydenham left it 200 years ago.

Of the Exciting Cause of Ague.—That the effluvia which arise from stagnant water or marshy ground are the immediate or the exciting cause of this disease is now universally admitted. What the nature of these effluvia is, is not known. Neither their physical nor their chemical properties have been ascertained. Even their presence is known only by their effects on the human constitution. No other test of their existence has as yet been ascertained. The most distinguished chemists have applied all the resources of their art to the investigation of this subject, but hitherto with so little success, that all which they have ascertained is the mere fact, that in certain situations an aëriform substance is generated capable of producing intermittent, remittent, and continued fever, together with several other painful and dangerous diseases. Some conjecture that this poisonous gas is carbonic acid; others that it is azote; others again that it is hydro-carburetted gas, or hydro-sulphuretted gas, or an undiscovered compound of azote and oxygen called septon. But chemistry has yet to discover even whether this poison be a simple substance or a compound body, as well as by what test, other than its action on the human body, its presence may be determined.

Though this poison be generated in the greatest abundance and intensity in marshy and swampy ground, yet without doubt it is also produced in situations which have none of the characters of a marsh. Wherever the ground is moist and contains decaying vegetable matter, this poison is capable of being generated. Woods afford it in almost as large a quantity as marshes, because in woods the ground remains a long time damp, and always abounds with decaying vegetable matter. Hence in all the densely wooded parts of England both intermittent and remittent fevers are rife. This is especially the case in the woody districts of Kent, Sussex, Hampshire, Wales, &c. The jungle of India consists of a low and dense brushwood, or a thicket of reeds and grass; and intense heat acting on the wet and decaying vegetation, with which it abounds, the poison is here produced in the highest degree of concentration. Rice grounds, for the same reason, are notoriously productive of it. But it is curious that the clearing of woods sometimes increases the evil. Dr. Rush states that, in Pennsylvania, epidemics invariably follow the clearing and cultivation of forest lands, and that they do not disappear until after many years of continued cultivation. The same remark has been made in France; and the district of Bresse, (Lyonnais,) which was comparatively healthy when full of woods, has become nearly depopulated since they were cut down. The shade of the trees kept the sun in a good measure from the wet ground; but the removal of the trees exposes the wet ground to the full action of the sun. Meadow land, imperfectly drained, contains in abundance the two conditions, moisture and decaying vegetable matter, and is in England a frequent and extended source of this poison. It is commonly considered that a large space of land in the condition of a marsh, a swamp, a thick and damp wood, or an undrained meadow is necessary to the production of the poison; but while it is not easy to fix the minimum of the space that is requisite, it is quite certain that an exceedingly small space is sufficient. These facts show, in a striking manner, the danger and folly of creating artificial marshes as ornaments in parks and gardens. ‘Hereafter,’ says Dr. Macculloch, ‘perhaps an English gentleman will be as much surprised that his neighbour should dig a sleeping canal before his door, as that his feudal ancestor should have built his castle in a marsh, and inclosed it with a putrid moat. The pond which has been constructed for a few gold fishes, or the river which meanders through the woody valley, is often the death spring of diseases; and the produce of a few bunches of rushes, or even a splendid display of water-lilies, are dearly purchased at the cost of the fevers and the toothaches which are the torments of the owner's family, the ailing wife who is his own torment, and the sciatica which is the torment of his poorer neighbours.’

Wherever generated, this poison, either mechanically mixed or chemically combined in the air, is capable of being conveyed in unimpaired power to a considerable distance by currents of wind. The influence of the Pontine marshes, situated at the distance of fourteen miles from Rome, is often felt in that city.

In warm climates, where this poison is generated in the highest degree of intensity, it sometimes proves suddenly fatal to individuals of a ship's crew when the vessel is several miles from land. It is brought with the land-wind. It seems certain that the poison can be carried as far as the smell of the land is perceptible. A memorable instance of this occurred in a vessel that was five miles from shore. The wind suddenly shifted; the smell of land was perceptible; the nature of the neighbouring coast was known to the people on board, and the danger duly appreciated; every one that could do so hastened below to save himself from the noxious breeze. Some of the crew, however, were unavoidably employed on deck; the armourer of the ship was detained a few minutes in order to clear an obstruction in the chain cable, and was seized with fatal cholera in the very act in which he was engaged. Of the men that remained on deck, several died of the same disease in a few hours, —the attack having been simultaneous with the very first perception of the land smell; and in our own country it is often conveyed by currents of wind to a distance of several miles. It frequently proceeds to the hills of Kent, for example, several miles distant from the marshes of Erith, Northfleet, or Gravesend. The watery vapour that is so apt to arise in situations most favourable to the generation of this poison appears to be an exceedingly formidable conductor of it. Sir John Pringle, who had many opportunities of observing this fact in the campaigns in Flanders, about the middle of the last century, uniformly found that the number of men who were seized with sickness during the prevalence of a fog, far exceeded the number attacked when the weather was clear, though he did not attribute to the fog the production of the poison, but justly considered it as merely the conductor of it.

But to whatever distance a current of wind or a dense fog may be capable of conveying this poison in sufficient quantity and concentration to produce disease, yet there cannot be a question that the poison is most intense the nearer to the marsh and the closer to the ground. Persons who live within a certain distance of an unhealthy spot often suffer severely, while those who reside at a somewhat greater distance escape. Persons who live in the basement story of a damp and undrained house, and especially those who sleep there, are constantly attacked with fever, while those who live in the upper apartments of the same house remain free from disease.

There are spots in which this poison is generated in such quantity and intensity as to be capable of killing instantaneously whoever is exposed to it. Exposure to it in certain situations has proved fatal with a rapidity and certainty equalled only by a mortal dose of Prussic acid. Exposure to it in other situations produces what may appear to be, and what is sometimes mistaken for, apoplexy—an affection of the brain causing death more rapidly than almost any other disease to which the human body is subject. Exposure to it when less concentrated produces malignant fever of a continued form, destroying life in a few days or hours. Exposure to a still smaller concentration produces remittent, and to a yet smaller, the milder form of intermittent fever. And it may be so minute in quantity or so destitute of virulence in its own nature, as to be incapable of producing even intermittent fever, in its regular and well-marked form, and yet sufficiently potent to produce a long catalogue of grievous maladies. The secondary diseases which have this origin, and which have been much overlooked, consist for the most part of those painful affections of the nerves, which have been lately classed together under the general term of *neuralgia.* The exquisitely painful, and too often unmanageable diseases called tic douloureux, the disease called sciatica, the toothache, and more especially periodical headache, are oftentimes clearly traceable to this poison, and are as certainly produced by it as the most distinct and regular ague. Persons who live in situations where this poison is generated in abundance may never have ague, but at the same time they never enjoy a moment's health; while it is certain that long-continued exposure to it, though it may not produce any specific disease, included in the catalogue of the nosologist, fearfully abridges the term of life. Few persons in such situations attain the age of fifty. In some parts of America, few of the inhabitants formerly lived beyond the age of forty; those who survived thus long had, at that early period, all the characters of extreme old age; already in those very situations, by the clearing, draining, and general cultivation of the land, the average term of life has been extended fifteen or even twenty years. There can be no question that the value of life which, in modern times, has increased so much in our own country, and which has improved in the rural districts in proportion to the better cultivation and the more complete draining of the land; and in the larger towns and cities to the better ventilation and the greater cleanliness for which they have been remarkable, has been mainly owing to these causes. So recently as the beginning of the present century, a celebrated physician, who had large experience of this matter, states, as a fact that came within his own observation and experience, that in small villages, in which the annual number of persons attacked with ague amounted to 200, not one case had occurred for several years.

Dr. Macculloch gives a vivid and but too faithful picture of the external appearance and of the constitutional disorder of the people who constantly reside in the midst of this poison, and who are not suddenly cut off by it under some acute form of disease.

Of the remote or predisposing Cause. It has been stated* that the remote, or the predisposing cause of disease is that which brings the system into a condition capable of being affected by the immediate or exciting cause. Whatever diminishes the vigorous action of the organs, impairs their functions, and so weakens the general strength of the system, is capable of becoming a predisposing cause of fever; and every predisposing cause acts in one or other of these modes, and becomes a predisposing cause only and in proportion as it lessens the energy of the system, or disturbs the balance of its actions, which in fact is to render some portion of it weak. During a state of vigorous health the body is endowed with the power of resisting the influence of noxious agents, which in a less perfect state of health are capable of producing intense and fatal disease; and the action of all predisposing causes is to lessen this resisting power, or to weaken the energies of life.

Of all the predisposing causes of ague the most powerful is the continued presence, and the slow operation of the immediate or the exciting cause. The manner in which the immediate or the exciting cause of fever operates as a predisposing cause has been amply illustrated by Dr. Southwood Smith. 'It is a matter of constant observation,' says this author, 'that the febrile poison may be present in sufficient intensity to affect the health, without being sufficiently potent to produce fever. In this case the energy of the action of the organs is diminished, their functions are languidly performed, the entire system is weakened, and this increases until at length the power of resistance is less than the power of the poison. Whenever this happens, fever is induced; not that the power of the poison may be at all increased, but the condition of the system is changed, in consequence of which it is capable of offering less resistance to the noxious agent that assails it.

'We have seen that the vegetable or animal poison may exist in sufficient intensity to produce fever on the slightest exposure to it, without the operation of any predisposing cause, in a body in the state of the soundest health, and endowed with the greatest degree of strength. Examples of this kind are but too frequent in tropical climates. In countries where the temperature never rises so high, and seldom continues so long, it is rare that fever is produced immediately on exposure to the exciting cause. Concentrated and potent as that poison is in many parts of Flanders, yet Sir John Pringle states that, "on removing to an unhealthy situation, the men rarely became ill at once; that they generally continued in tolerable health for some days; and that recruits recently arrived in the country resisted the noxious agent longer than the men who had been long there." Dr. Potter gives a remarkable example of the same fact, with regard to the yellow fever, which fell under his own observation, and states other facts strikingly illustrative of the influence and operation of the predisposing causes. Strangers, from certain countries, he informs us, are insusceptible of yellow fever in America. In the most malignant and protracted epidemics which afflict that country, these strangers uniformly escape; emigrants from the West Indies, and other warm latitudes, for example, invariably resist the cause which produces these maladies in the native inhabitants. But the curious fact is, that such persons are unable permanently to resist the operation of the exciting cause; for, after a residence in America of some years, their constitution is so completely assimilated by the influence of the climate to that of the American, that they become equally sensible to its febrile miasma, and are as exquisitely impressed by them as the American citizens themselves. The illustration is equally striking and instructive if the position be reversed. The natives of northern climates are extremely susceptible to the influence of these miasma; that susceptibility is in exact proportion to the latitude of their country: those from the north of Europe scarcely ever escape an attack; the natives of Great Britain are nearly as susceptible to the influence of the poison, while persons even from the more northern countries of the United States are more liable to the disease than the citizens of the southern and middle states.’

---

* See Treatise on Fever by Dr. Southwood Smith.

Among the other predisposing causes may be reckoned the period of life. All persons between the age of puberty and that of thirty-eight are peculiarly predisposed to this disease. After the disease has once existed, there remains in the constitution a remarkable susceptibility to its recurrence; and that from very slight causes, as from the prevalence of an easterly wind, or exposure to a very minute quantity of the poison that originally produced it, such as would not affect a person who had never been the subject of the disease. Hence, persons who have been once or twice, or oftener affected with ague, are most delicate tests of the presence of the exciting poison. Deficient and poor diet; intemperance; physical and mental fatigue; anxiety, cold, damp, debility, however induced—all these are extremely powerful predisposing causes. They enable a less dose of the poison to produce the fever, and they increase the intensity of it when established. They all act by weakening the resisting power inherent in the constitution, that is, by enfeebling the powers of life. In a vigorous state of the health, exposure to the poison, even in a concentrated state, may occasion no mischief, because the resisting power of the constitution may be greater than the power of the poison, but no human strength can resist a continued exposure to it; for, as has been already stated, if such long-continued exposure do not produce disease in the form of ague, it will certainly produce it in some other shape; which, if it do not immediately kill, will assuredly shorten life.

Of the Cure.—The first object in the treatment of a person affected with ague is to remove him from the influence of the poison by taking him out of an unhealthy, and placing him in a healthy situation. Unless this can be done, every remedy employed must act at a great disadvantage, and the power of the poison, or the debility of the patient, may be such as to render every effort to cure the disease unavailing without a change of residence. Often, however, circumstances will not admit of the removal of the patient. Whenever this is the case, the sick person must at least be put and kept in an apartment the most remote from the noxious spot, and it is a good and important general rule to place him in the highest part of the house. When this precaution is neglected, remedies constantly fail which readily and completely succeed when it is observed.

A vast variety of medicines have been recommended as sovereign remedies in this disease, and such an enumeration may be useful to the experienced and judicious practitioner, because he knows how to select, and he may find in the catalogue what may suggest the precise modification adapted to any individual case of peculiarity and difficulty which he may chance to have in hand. But the student and the young practitioner require more precise direction, and the mode of procedure which proves the most effectual in the great majority of cases cannot be too clearly and definitely pointed out.

Passing by the treatment adapted to the severest cases that occur in hot climates, in which, indeed, human art is too often of no avail whatever, we are fortunate in possessing three remedies, the proper employment of which seldom fails to cure the most formidable and inveterate intermittent which ever occurs in this country, namely, ipecacuanha, bark, and arsenic.

The treatment of ague includes the management during the paroxysm, the intermission and the convalescence. None of these remedies is suitable to all these periods, and what will effectually cure in one, may prove positively *injurious in another.*

First of the treatment during the paroxysm. The approach of the paroxysm should be carefully watched. The moment the first indication of its accession is apparent, whether that indication be afforded by a return of languor, or listlessness, or pain of the head, or a sense of confusion, or, above all, of coldness or chilliness, an emetic, consisting of twenty grains of the powder of ipecacuanha with one grain of the tartar emetic, should be given. The operation of the emetic may be promoted by drinking freely warm water, or warm chamomile tea *after* (*but not previously*) the first act of vomiting has occurred. As soon as the operation of the emetic is over, a draught should be taken, consisting of forty drops of laudanum in an ounce and a half of camphor julep. This plan, in almost all cases, will completely stop the coming on of the cold fit; in a great number of cases it will also prevent altogether the accession of the hot fit, inducing at once the sweating stage, that is, the stage which constitutes the solution of the paroxysm. But if it should not actually stop the accession of the hot stage, it will assuredly diminish its violence and shorten its duration; and as soon as the hot stage is formed, the laudanum should be repeated in smaller doses, namely, in doses of from ten to twelve drops, repeated every hour, and continued until the sweating stage is completely established.

As soon as the cessation of the sweating stage terminates the paroxysm, and the latter is succeeded by the stage of intermission, the bark should be freely taken. Of all the preparations of bark, the sulphate of quinine is incomparably the best. The dose is from two to four grains, and the most convenient mode of administering it is in the form of pill. During the whole period of the intermission, the dose of quinine should be repeated every hour, or every two hours, according to the urgency of the case. If the biliary secretion be unhealthy, which it almost always is, it will be useful to combine with every alternate dose of the quinine, from the sixth to the fourth part of a grain of blue pill, together with two grains of the extract of gentian. If the bowels be constipated, the addition to each pill of from one to two grains of the extract of rhubarb will form an excellent aperient. Given in this mode, the extract of rhubarb moderately, but in general effectually, stimulates the alimentary canal, gently increasing its action, without producing purging. If, however, the bowels be constitutionally torpid, or be rendered so by the disease, a more active aperient must be substituted, and such will be found in the compound decoction of aloes, or the infusion of senna with camomile. The condition of the bowels must never be neglected, for a state of constipation will powerfully counteract every remedy.

This plan should be continued without intermission until the recurrence of the symptoms which denote a fresh accession of the paroxysm. Then the quinine, &c. should be suspended, and the emetic should be again repeated, which, as soon as its action has ceased, should be followed by the opiate, and this, on the solution of the paroxysm, by the bark, and so on in a constant series, until the paroxysm return no more. By this method of treatment the disease is usually cured after the third accession, consequently it is seldom necessary to repeat the emetic more than three times, and often twice and even once is sufficient. Formerly there was a great difficulty in exhibiting the bark. From one to two drachms of the powder was prescribed every hour, and nothing was thought to be accomplished unless from one to two ounces were accumulated in the stomach before the expected return of the paroxysm. There were few stomachs which could bear this quantity, and accordingly all sorts of combinations with aromatics and spirits were tried, but commonly tried in vain, to enable the stomach to retain it. The system, besides being oppressed by the disease, was thus still further harassed by the disorder of the stomach and bowels occasioned by the remedy. The preparation of quinine has obviated all these difficulties, and the science of medicine owes a large debt of gratitude to chemistry, for the wonderful simplification and concentration of the most potent remedies which it has effected. One grain of quinine will accomplish more than a dram of the bark. The necessity of taking fifty-nine drams of useless matter which oppressed and irritated the stomach, already in a weak and irritable state, is obviated, and consequently the cure is much more easily and rapidly effected.

Bark, however powerful and effectual during the intermission, is commonly conceived to be useless and even pernicious during the paroxysm. But this is the period when opium is most effectual. It has now been tried on a very large scale, and the favourable report of it by those who first tried it has been fully confirmed by subsequent experience. Extended opportunities for observing ague do not occur in London, and when they do occur, the cases are never, perhaps, the most formidable. Cases, however, are continually occurring, and we have witnessed more than enough to satisfy us of the speedy and most beneficial effects of opium, especially when the exhibition of it has been preceded by an emetic. It has, however, been given with success as the sole remedy. Dr. Trotter, who had an opportunity of observing its effects on a large scale in the Channel fleet, under Earl Howe, states, that whenever the sick felt the first approach of an attack, he prescribed from thirty to forty drops of laudanum; that if this dose did not bring on some warmth in the course of ten or fifteen minutes, he gave from twelve to fifteen drops more; that it was seldom necessary to increase the quantity beyond sixty drops in the space of an hour, decided relief being always afforded in that time; that in a few minutes from the exhibition of the opiate the spirits became exhilarated; the constriction on the skin was removed, and was followed by relaxation; the countenance looked more animated; a flush spread itself over the cheek; the pulse, from having been weak, quick, irregular, and sometimes intermittent, became less frequent, and more full and more equal; an agreeable warmth was diffused over the whole frame, and every unpleasant feeling vanished sometimes in a quarter of an hour. As soon as any symptoms indicated a return of the paroxysm, the laudanum was repeated in the same manner as at the accession of a former fit, and always with equal success, so that the patient seldom experienced much trembling and shaking; it was observed that the second paroxysm was commonly an hour or two later in the day than the preceding, and but few instances occurred of a return of the disease after the third paroxysm. The patients themselves were so satisfied of the efficacy of this remedy, that the moment they felt the first approach of an attack, they were sure to run to the cockpit for relief.

Dr. Lind, who also tried this remedy on a large scale, states, that, according to his experience, the good effects of opium are more uniform and powerful in intermittent fever than in any other disease, and that it affects the disease more rapidly than any other medicine; that if taken during the intermissions, it has no effect either in preventing or mitigating the succeeding paroxysm; that when given in the cold fit, it occasionally removed it; but that when administered half an hour after the commencement of a hot fit, it almost always afforded immediate relief. 1. It abated the violence of the fit and shortened its duration. 2. It relieved the head, put an end to the burning heat, and brought on a profuse sweat, which was more copious than when not occasioned by opium, and attended with a softness of the skin instead of the intense burning sensation common in the sweating stage. 3. It constantly produced a tranquil and refreshing sleep, from which the patient awoke bathed in sweat, and in a great measure free from all complaint. From the speedy and complete solution of the attack, it is contended that this remedy not only shortens the duration of the disease more than other medicine, but more effectually preserves the constitution from injury, insomuch that, after its use, it is seldom that dropsy, jaundice, or ague, disease of the liver, spleen, or any other viscus, is witnessed. According to this physician, opium is the best preparative for the bark; since it not only produces a complete intermission, in which case alone the bark is effectual or even safe, but it occasions such a copious and salutary evacuation by sweat, as generally to render a much less quantity of bark requisite.

The names just cited are both good and independent authorities, their statements are the result of observation and experience, and they show in a striking manner the efficacy of the practice we have recommended, which is also derived from ample experience.

When the intermittent is of long continuance, or when the patient is advanced in years and weak, or when the season is rainy, or the situation damp, it will be advisable to add serpentaria to the quinine, and to combine some aromatic with both. Thus the quinine may be given in two ounces of the infusion of serpentaria, with a dram of the compound tincture of cardamom, and a scruple of the aromatic confection.

It is not sufficient that the recurrence of the paroxysm has been stopped once or twice by the use of the remedies prescribed. It should be borne in mind that there is in this disease a great tendency to relapse, and this tendency continues through the whole period of convalescence, and for some time after. The quinine should be continued in smaller doses for some weeks after the last paroxysm has supervened, especially if the weather be damp or easterly winds prevail.

If aperients are necessary, they should be warm and aromatic, and given during the intermission, so that their operation may be over before the accession of the paroxysm.

When an ague is severe, obstinate, neglected, ill treated, or attacks a person whose constitution was previously unsound, organic disease is occasionally produced, which always renders the treatment difficult and the cure uncertain. The organs that are most liable to be diseased are the liver and the spleen; these become enlarged and hardened, schirrous, as it is technically termed. The tumors occasionally press upon the great veins of the liver, and prevent the blood from passing freely from the abdominal viscera; the passage of the blood being retarded, the serum or the fluid part of the blood is exhaled into the cavity of the abdomen in greater quantity than the absorbents can take up, consequently it accumulates and thus forms dropsy.
